T. Fleitmann and W. Henneberg prepared sodium ferric pyrophosphate by boiling ferric pyrophosphate in excess with a soln. of sodium pyrophosphate, and precipitation with alcohol. W. H. Milck used an analogous process. Analyses of the salt were made by T. Fleitmann and W. Henneberg, J. H. Gladstone, J. Persoz, and W. H. Milck. The best representative value is: $2\text{Na}_4\text{P}_2\text{O}_7\cdot\text{Fe}_4(\text{P}_2\text{O}_7)_3\cdot 14\text{H}_2\text{O}$. The salt obtained by precipitation is colourless and easily soluble. The soln. can be evaporated to a syrupy consistency without becoming turbid, but it is thereby partially decomposed. A. Naumann observed that the complex salt is insoluble in acetone. According to W. H. Milck, no turbidity or discoloration appears if the aq. soln. be left to evaporate spontaneously for a month. When treated with hydrogen sulphide, the soln. becomes brown, and deposits sulphur; with ammonium sulphide, a green colour develops. Sodium chloride precipitates the salt from its soln.; ferric chloride precipitates ferric pyrophosphate; acids precipitate white ferric phosphate; potassium thiocyanate gives a white jelly soluble in excess. M. Rieckher said that the soln. is not precipitated by ammonium carbonate, alkali hydrocarbonates, potassium thiocyanate, sodium phosphate, or alkali acetates or succinates; freshly-precipitated barium carbonate does not precipitate ferric oxide. The soln. is not reduced by metallic iron, but it is by stannous chloride which also produces a white precipitate. W. H. Milck added that with ammonia, the soln. acquires a reddish colour, and if the boiling soln. be then evaporated, a red precipitate appears, which is soluble in ammonia, and on adding alcohol to the soln., a triple salt is deposited.

S. Frommer and W. Händler prepared **sodium ferric hydroxypyrophosphate**, $\text{Na}[\text{Fe}(\text{OH})(\text{P}_2\text{O}_7)]\cdot n\text{H}_2\text{O}$, as a *pentahydrate*, and *hemitrihydrate*; also **sodium ferric dihydroxypyrophosphate**, $\text{Na}_3[\text{Fe}(\text{OH})_2(\text{P}_2\text{O}_7)]\cdot 4\text{H}_2\text{O}$, but not the potassium and ammonium salts. They also prepared **sodium ferric pyrophosphate**, $\text{Na}_2[\text{Fe}(\text{P}_2\text{O}_7)]\cdot 2\frac{1}{2}\text{H}_2\text{O}$, and **ammonium ferric pyrophosphate**, $(\text{NH}_4)_2\text{Fe}(\text{P}_2\text{O}_7)\cdot 2\text{H}_2\text{O}$. P. Pascal emphasized the masking of the iron in sodium ferric pyrophosphate so that the soln. is simply coloured reddish-yellow when ammonia is added. When ammonia, of sp. gr. 0.880, is added to a soln. obtained by mixing 15 per cent. soln. of ferric chloride and sodium pyrophosphate, the liquid is coloured red, and

there are produced (i) a crystalline precipitate equal to one-third of the sodium pyrophosphate used ; (ii) a layer of red clots surmounted by one of yellow clots at the junction where the two liquids initially separate ; and (iii) long, silky, felted needles in the upper part of the liquid. All three products are **sodium ferric amminopyrophosphates** in which the iron is masked in the presence of the usual reagents for the detection of ferric salts. The ammines are not well-defined. P. Pascal observed that when the soln. of the sodium salt, $\text{Na}_6\text{Fe}_2(\text{P}_2\text{O}_7)_3 \cdot 9\text{H}_2\text{O}$, is treated with a soln. of a copper salt, greenish-blue **copper ferric pyrophosphate**, $\text{Cu}_3\text{Fe}_2(\text{P}_2\text{O}_7)_3 \cdot 12\text{H}_2\text{O}$, and with a soln. of a silver salt, greenish-yellow **silver ferric pyrophosphate**, $\text{Ag}_6\text{Fe}_2(\text{P}_2\text{O}_7)_3 \cdot 4\text{H}_2\text{O}$, are formed.

The acidic salt, $\text{Fe}_2\text{O}_3 \cdot 3\text{P}_2\text{O}_5$, prepared by P. Hautefeuille and J. Margottet, can be regarded not only as the dihydrophosphate, but also as **ferric trimetaphosphate**, $\text{Fe}(\text{PO}_3)_3$; the other two hydrates become respectively the *trihydrate*, $\text{Fe}(\text{PO}_3)_3 \cdot 3\text{H}_2\text{O}$, and the *dihydrate*, $\text{Fe}(\text{PO}_3)_3 \cdot 2\text{H}_2\text{O}$. R. Maddrell²¹ first prepared the salt by adding ferric chloride to an excess of a dil. soln. of metaphosphoric acid, concentrating the liquid, and heating the residue to 315° . P. Hautefeuille and J. Margottet obtained it from a sat. soln. of ferric oxide or phosphate in metaphosphoric acid ; and K. R. Johnson, from a soln. of anhydrous ferric sulphate in that acid when the mixture is heated until crystallization sets in. The salt has a sp. gr. 3.02. It is insoluble in water, and dil. acids, but soluble in conc. sulphuric acid. P. Pascal found that **sodium ferric metaphosphate**, $\text{Na}_3\text{Fe}(\text{PO}_3)_3$, can be prepared from a soln. of sodium and ferric metaphosphates. P. Hautefeuille and J. Margottet obtained **silver ferric metaphosphate**, $2\text{Ag}_2\text{O} \cdot 2\text{Fe}_2\text{O}_3 \cdot 5\text{P}_2\text{O}_5$, in high refractive, rose-coloured prisms, from a fused mixture of silver phosphate and ferric metaphosphate. S. Freed and C. Kasper discussed the complex ion, $[\text{Fe}(\text{PO}_3)_6]^{3-}$.

A. Glatzel obtained **ferric tetrametaphosphate** by melting a ferrous or a ferric salt with a small excess of phosphoric acid, and slowly cooling the product. The violet crystals are insoluble in water, and hydrochloric or nitric acid ; they are partly decomposed by sulphuric acid. H. Lüder reported that **ferric hexametaphosphate** is not produced when sodium hexametaphosphate is treated with ferric chloride.

M. Stange²² was unable to prepare **sodium ferric triphosphate**, analogous with the corresponding ferrous salt, $\text{Na}_3\text{FeP}_3\text{O}_{10} \cdot 11\frac{1}{2}\text{H}_2\text{O}$.

CHAPTER LXVII

COBALT

§ 1. The History of Cobalt

THE terms *kobalt*, *kobold*, *kobald*, *kobelt*, *kobolt*, *cobel*, *cobelt*, *cobalt*, etc., appear in the mining and mineralogical literature of the sixteenth century. G. Agricola,¹ in 1530, first used the term *kobelt* for a mineral, although, according to V. Ducange, the term was employed in 1335, in some chronicles of Leoben, for the gnomes living in the mines. *Kobold* is the German word for gnomes and goblins, and it is applied by the miners to the ore partly on account of the worthlessness of the ore, and partly on account of its mischievous effects on their own health owing to the arsenic also present in the ore. The suffering was attributed to the work of malevolent gnomes. Later, the term was extended to include the disagreeable ore. Thus, C. Encelius, in 1551, said that the name was used for a pyritic ore, and also for a metal. Similarly with G. Dorneus, M. Ruland, J. K. G. Jacobsen, D. I. Walchin, and W. Johnson. J. Mathesius, in 1562, in a series of mining sermons, wrote :

Sometimes, however, from dry, hard veins a certain black, greenish, grey or ash-coloured earth is dug out often containing good ore, and this mineral being burnt gives strong fumes and is extracted like "tutty." It is called *cadmia fossilis*. You miners call it *cobelt*. Germans call it the Black Devil and the old Devil's furies, old and black *cobel*, who injure people and their cattle with their witchcrafts. Now the Devil is a wicked, malicious spirit, who shoots his poisoned darts into the hearts of men, as sorcerers and witches shoot at the limbs of cattle and men, and work much evil and mischief with *cobalt* or *hipomane* or horses' poison. After quicksilver and *rotgültigen* ore, are *cobalt* and *wismuth* fumes ; these are the most poisonous of the metals, and with them one can kill flies, mice, cattle, birds, and men. So, fresh *cobalt* and *kisswasser* [vitriol] devour the hands and feet of miners, and the dust and fumes of *cobalt* kill many mining people and workpeople who do much work among the fumes of the smelters. Whether or not the Devil and his hellish crew gave their name to *cobelt*, or *kobelt*, nevertheless, *cobelt* is a poisonous and injurious metal even if it contains silver. I find in 1 Kings 9, the word *Cabul*. When Solomon presented twenty towns in Galilee to the King of Tyre, Hiram visited them first, and would not have them, and said the land was well named *Cabul* as Joshua had christened it. It is certain from Joshua that these twenty towns lay in the Kingdom of Aser, not far from our *Sarepta*, and that there had been iron and copper mines there, as Moses says in another place. Inasmuch, then, as these twenty places were mining towns, and *cobelt* is a metal, it appears quite likely that the mineral took its name from the land of Cabul. History and circumstances bear out the theory that Hiram was an excellent and experienced miner, who obtained much gold from Ophir, with which he honoured Solomon. Therefore, the Great King wished to show his gratitude to his good neighbour by bestowing on him a number of mining towns. But because the King of Tyre was skilled in mines, he first inspected the new mines, and saw that they only produced poor metal and much wild *cobelt* ore, therefore he preferred to find his gold by digging the gold and silver in India, rather than by getting it by the *cobelt* veins and ore. For truly, *cobelt* ores are injurious, and are usually so embedded in other ores that they rob them in the fire and consume (*madtet und frist*) much lead before the silver is extracted, and when this happens it is especially *speysig*. Therefore Hiram made a good reckoning as to the mines and would not undertake all the expense of working and smelting, and so returned Solomon the twenty towns.

In 1783, J. C. Adelung said that the metallurgists applied the term cobalt to ores—called *false ores*—which gave no metal when smelted ; and in 1773, J. G. Krünitz

added that the miners applied the term *kobalt* or *kobolt* to all earths they did not know, and that later, the term was applied to earths which coloured glass blue.

The term *cobalt* or *kobold* is said to be derived from the Greek *κόβαλος*, a mine. M. Berthelot suggested that the word is of Grecian or Egyptian origin; and E. Merck derived it from the slavonic *kowalti*, metallic. W. W. Skeat, and J. Berenides, thought that the word might have come from the Greek *κόβαλος*, a parasite, because the cobalt is usually associated with nickel; but this cannot be right, since nickel was not discovered until three centuries after the word cobalt had been in use. It is more probable that the word is of Germanic origin, and has nothing to do with Latin or Greek. The term *kobold*, at first employed locally by the miners in the Harz or Erzgebirge, became common German, and then passed into all the European languages—*vide* nickel.

According to L. Franchet, cobaltiferous earth was used by the Egyptians for colouring certain statuettes blue. The inscriptions of these figures show that they belonged to the 22nd Dynasty—about 3000 years ago. According to H. V. Hilprecht, and E. Darmstaedter, cobalt was also used for decorating pottery by the early Persians, Babylonians, Assyrians, Arabians, and the Chinese. According to B. Neumann, the ancient glasses and the glazes and bodies of many of the early Egyptian figures are coloured with copper—6. 40, 25—but, according to L. Franchet, a bluish-black cobalt colour was also employed. B. Neumann said that the glazes on the Alexandrian, Roman, and Byzantine ware which he examined owe their blue colour to copper, and not cobalt.

J. F. Gmelin, H. D. Richmond and H. Off, and M. H. Klaproth could not detect the presence of cobalt in antique glasses, but H. Davy, J. J. Ferber, J. B. J. Fourier, and X. Landerer found samples of cobaltiferous blue glass in the ruins of Pompeii, etc.; and B. Neumann observed cobalt in some ancient Venetian glasses.

The early alchemists prepared the cobalt pigment by roasting the natural mineral so as to eliminate sulphur and arsenic, and they called the product *safré*. This is not to be confounded with *azur*, which Pliny, in his *Historia naturalis* (33. 517), tells us was a blue enamel obtained by fusing cupriferous minerals with a flux. Later the term *azur* was also applied to a blue derived from cobalt as well as from copper, for P. J. Macquer said in 1789:

'The vitreous glass obtained by fusing a cobalt ore with a flux is called *smalt* when it is *en masse*, and in commerce it takes the name *azur* when it has been reduced *en poudre*.

C. Piccolpassi used roasted cobalt ore for decorating pottery about 1548, and he said that the *safré* which comes from Venice, gives a brownish-violet colour. C. Piccolpassi also applied the term *bleu azur* generally to cobalt blues. In the first half of the sixteenth century, some special earths were employed for colouring glass blue. They were prepared by mixing roasted cobalt earth with sand, and different names—*sapphire*, *zaphara*, *zaphera*, *zapher*, *zaffre*, *saffra*, *safflor*, and *saffran*—were applied to the preparations by H. Cardanus, A. Cæsalpinus, J. B. Porta, and A. Libavius. Clear directions were given by J. von Kunckel, in 1679, for the preparation of *zaffre* by heating the roasted mineral mixed with sand, and of *smalt*, by fusing the mineral with sand. The history of the subject was discussed by J. C. Scaliger, C. Melzer, A. Neri, C. Merret, J. von Kunckel, W. Bruchmüller, H. Kopp, F. Kapff, and B. Neumann.

In 1540, V. Biringucci mentioned the use of *zaffera* as a mineral which does not melt alone, but which, when mixed with vitreifiable substances, melts to form an azure-blue pigment for staining glass, or pottery glazes, blue. He did not connect *zaffera* with the ores then called cobalt. G. Agricola referred to cobalt-blue, but he also missed the relation between cobalt ore and *zaffre*, for he considered that the *zaffre* came from the bismuth ore. This belief was based on the fact that the cobalt ore of Erzgebirge occurs in intimate association with bismuth ore. G. Agricola also said that "the slag of bismuth, mixed with metalliferous substances, which when melted make a kind of glass, which tint glass and earthenware glazes blue."

G. Agricola, and others indicated above, indeed, were much confused as to the zinc, cobalt, and arsenic minerals, so that cadmia and cobalt were considered to be similar things.

In the sixteenth or seventeenth century, Basil Valentine² included cobalt in a list of metallic ores; and in the sixteenth century, Paracelsus stated that a metal is produced from cobalt "which is fluid like zinc, with a peculiar black colour, beyond that of lead and iron, and possessing no brightness or metallic lustre. It is capable of being wrought, and is malleable, but not to such an extent as to fit it for practical use." There is, however, nothing here to show that Paracelsus referred to the metal now understood by cobalt.

In 1742, G. Brandt³ showed that the blue colour of smalt is due to the presence of cobalt, which he regarded as a demi-metal. He obtained a regulus of cobalt, which he called *cobalt rex*, by reducing the ore, and observed that it has a grey colour with a rosy tinge, and that it may be lamellar, granular, or fibrous according to the temp. employed in reducing the metal. Like iron, too, the metal is magnetic. G. Brandt showed that the metal cobalt is free from bismuth, and that in the absence of cobalt, bismuth does not colour glass blue. A soln. of bismuth in nitric acid gives a white precipitate when treated with water, but not so with a similar soln. of cobalt. G. Brandt also showed that the blue colour of smalt is not produced by iron or by arsenic, but is solely due to the presence of cobalt. In spite of this, both J. G. Lehmann, and J. F. Henckel attributed the blue coloration to the presence of iron, or of iron and arsenic. The elemental character of cobalt was subsequently established by the work of T. Bergman,⁴ B. M. Tassaert, C. F. Bucholz, R. Kirwan, F. Kapff, J. B. Richter, L. J. Thénard, and J. L. Proust. The history of cobalt was discussed by D. F. Hehnemann, and M. E. Weeks.

In 1653, P. Borel⁵ suggested that invisible writing could be made by using a soln. of lead acetate in place of ordinary ink; the writing to be afterwards made visible by a soln. of a sulphide. The term *atramentum sympatheticum* was applied by J. le Mort to the invisible ink, whilst N. Lemery used the term *l'encre sympathique* for the *sympathetic ink*. Salt soln. of other metals were recommended as sympathetic inks by G. Homberg in 1698; and in 1705, D. J. Walchin recommended a soln. of bismuthiferous cobalt. The invisible writing became grass-green when heated. According to J. H. Pott, the cobalt sympathetic ink was made by a German lady at the beginning of the eighteenth century, and by H. F. Teichmeyer, about 1731. J. Hellot also relates that a German artist of Stollberg showed a cobalt sympathetic ink to him. A similar ink was suggested by F. Hoffmann in 1732; and J. Hellot, in 1737, first published recipes for preparing this sympathetic ink. J. H. Pott attributed the phenomenon to the presence of a bismuth salt, but J. A. Gesner showed that the effect is not due to the bismuth, but rather to the cobalt. The subject was discussed by G. Homberg.

H. D. Richmond and H. Off⁶ thought that they had discovered a new element in the alum of Egypt, and they called it *masrium*, from *Masr*, the Arabic name for Egypt. Nothing further developed from the alleged discovery. J. B. Richter reported a new element to be present in cobalt ores, and it was called *niccolanum*, but it was afterwards shown to be a mixture of nickel, cobalt, arsenic, and iron. W. A. Lampadius also reported a new element in these ores, and he called it *wodanium* after the mineral *wodankies*—now *gersdorffite*—in which it was found. F. Stromeyer, however, showed that the alleged new element was a mixture of nickel, arsenic, etc. The element *gnomium*, reputed by G. Krüss and F. W. Schmidt to be present in ordinary cobalt and nickel, was disproved by C. Winkler.

§ 2. The Occurrence of Cobalt

As emphasized by K. Kraut,¹ cobalt is widely diffused in nature, but not abundantly. It occurs combined usually as sulphide or arsenide, or in oxidized derivatives of these compounds. According to F. W. Clarke and H. S. Washington, the relative abundance of cobalt in the igneous rocks of the earth's crust is 0.001, when that of nickel is 0.020, and that of iron is 5.01 per cent. J. H. L. Vogt

gave 0.00n; and W. Vernadsky, 0.001. A. E. Fersmann calculated 0.00029 for the percentage number of atoms in the earth's crust. W. and J. Noddack and O. Berg gave 3×10^{-6} for the absolute abundance of cobalt in the earth; 3×10^{-5} for nickel; and 10^{-2} for iron. The general subject was also discussed by A. von Antropoff, E. Dittler, G. Tammann, J. L. Howe, W. D. Harkins, V. M. Goldschmidt, E. Herlinger, G. Berg, O. Hahn, W. Lindgren, P. Niggli, R. A. Sonder, H. S. Washington, and J. Joly—*vide* the occurrence of iron.

Cobalt alloyed with iron and nickel is of extra-terrestrial origin. F. Behrend and G. Berg,² E. Cohen, J. M. Davison, A. F. Foote, V. M. Goldschmidt, H. Haushofer, W. E. Hidden, J. L. Howe, J. F. John, M. H. Klaproth, H. von Klüber, S. M. Losanitsch, A. Madelung, G. P. Merrill, P. Niggli, J. and W. Noddack, W. Ramsay and L. H. Borgström, H. N. Russell, A. Ben-Saude, F. Stromeyer, W. Tassin, W. J. Taylor, G. Trottaelli, J. H. L. Vogt, M. E. Wadsworth, E. Weinschenk, and J. E. Whitfield have reported the occurrence of cobalt in meteorites. E. Cohen agrees with J. L. Smith that cobalt is present in all the meteorites that he examined. The amount varies from about 0.5 to 2.5 per cent.—according to G. Berg, and E. Herlinger, on the average, 0.07 per cent. in stoney meteorites, and 0.58 per cent. in iron meteorites. G. P. Merrill estimated that the analyses published up to 1916 showed that meteorites contained 0.07 per cent. of metallic cobalt and 0.06 per cent. cobalt oxide. J. and W. Noddack's estimates for the percentage distribution, and the relative atomic distribution with oxygen unity, are:

Earth's crust	Igneous rocks	Meteoric iron	Troilite	Atomic distribution
1.8×10^{-5}	1.8×10^{-4}	5.47×10^{-3}	2.08×10^{-3}	2.7×10^{-3}

In some of the earlier analyses cobalt was not specially sought for, and its presence may therefore have been overlooked. Only in a few cases has cobalt been sought and not found. V. de Luynes, J. J. Berzelius, E. Geinitz, P. G. Melikoff and L. Pissarjewsky, I. Domeyko, W. P. Blake, and H. A. Prout discussed the subject.

The spectral lines of the sun were found by G. Kirchhoff,³ H. M. Vernon, F. McClean, H. A. Rowland, C. Young, C. G. Abbot, W. W. Morgan and G. Farnsworth, F. J. M. Stratton, H. von Klüber, H. N. Russell, J. and W. Noddack, S. A. Mitchell, C. E. St. John, J. N. Lockyer; J. N. Lockyer and F. E. Baxendahl, A. de Gramont, W. F. Meggers, W. S. Adams, and A. Cornu to agree with the assumption that cobalt is present in the sun. The occurrence of cobalt in stellar atmospheres has been discussed by H. von Klüber, C. H. Payne and C. P. Chase, T. Dunham, G. E. Hale and co-workers, C. D. Shane, and V. M. Goldschmidt. J. N. Lockyer and F. E. Baxendahl observed no signs of cobalt in stellar spectra.

F. Beyschlag⁴ and co-workers estimate that the available analyses of terrestrial materials and of meteorites show that the cobalt and nickel occur in relative proportions between 1:8 and 1:20.

Cobalt ores occur in veins along with other minerals—*e.g.*, silver, bismuth, etc.—so that the cobalt is only of secondary importance; they also occur in surface concentrations of decomposition products of the weathering of basic igneous rocks—*e.g.*, serpentized dunites or peridotites. The vein occurrences occur in different kinds of rock—*e.g.*, crystalline limestone, clay-slates, conglomerates, quartzite, schists, etc. The characters of the enclosing rocks are so varied that they furnish no clue to the origin of the cobalt. It is generally supposed that the vein deposits are of thermal origin having been transported by, and deposited from, magmatic waters of considerable depth. This is confirmed by the fact that the cobaltiferous veins are nearly always in the immediate vicinity of intrusive igneous rocks—*e.g.*, the deposits of Ontario, Canada. In some cases the veins have a dual origin, having been deposited from magmatic, and meteoric waters. Surface agencies may have altered the primary ore to form secondary minerals like erythrite. The subject has been discussed by A. E. Barlow, A. P. Coleman, A. C. Dickson, R. Beck, C. W. Knight, W. G. Miller, C. E. Ellsworth, W. Campbell and C. W. Knight,

C. Palmer and E. S. Bastin, M. E. Wilson, F. Beyschlag and co-workers, V. M. Goldschmidt, G. Berg, F. Weinert, J. H. L. Vogt, P. Niggli, H. Schneiderhöhn, A. Beutell, A. Bergeat, E. Commanducci, A. M. Finlayson, J. Roth, F. Sandberger, etc. Colloidal precipitations were studied by G. Berg, N. G. Chatterji and N. R. Dhar, P. B. Sarkar and N. R. Dhar, P. Krusch, G. A. Thiel, J. H. L. Vogt, W. Vernadsky, F. Behrend, S. Imori, A. Cissarz, and F. Beyschlag.

Metallic cobalt, in traces, occurs associated with other metals. For instance, the presence of cobalt has been noted in the iron of Ovivak, Greenland, by F. Wöhler,⁵ A. E. Nordenskjöld, E. Cohen, F. W. Clarke, K. J. V. Steenstrup, C. Benedicks, W. Eitel, J. L. Smith, A. Daubrée, R. Naukhoff, and G. Tschermak; in the platinum metals, by P. Krusch, and L. Duparc and M. Tikanowitch; and in the silver of cobalt, Ontario, by T. L. Walker.

The more important cobalt minerals are: cobaltite, linnæite, skutterudite, smaltite, cobaltiferous pyrites, glaucodote, asbolan, and erythrite. The cobalt minerals include:

Alloclasite, $(\text{Fe}, \text{Co})(\text{As}, \text{Bi})\text{S}$, with part of the cobalt replaced by iron. **Annabergite**, $(\text{Co}, \text{Ni})_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$. **Asbolan**—see asbolite. **Asbolite**, asbolan, earthy cobalt, or wad, an impure mixture of manganese and other oxides containing variable proportions, 4.05 to 34.37 per cent., CoO ; that from Djebel Debar approximates $\text{CoO} \cdot 2\text{MnO}_3 \cdot 4\text{H}_2\text{O}$. **Badenite**, $(\text{Co}, \text{Ni}, \text{Fe})_3(\text{As}, \text{Bi})_4$, or $(\text{Co}, \text{Ni}, \text{Fe})_2(\text{As}, \text{Bi})_3$. **Bieberite**, $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$. **Bismuto-smaltite**, $\text{Co}(\text{As}, \text{Bi})_2$ —a skutterudite containing bismuth. **Bismuth skutterudite**, $(\text{Fe}, \text{Co})(\text{As}, \text{Bi}, \text{Sb})_3$. **Cabrerite**, $(\text{Ni}, \text{Mg}, \text{Co})_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$. **Carrollite**, CuCo_2S_4 , or $\text{CuS} \cdot \text{Co}_2\text{S}_3$. **Cobalt bloom**—see erythrite. **Cobalt glance**—see cobaltite. **Cobalt ochre**—see erythrite. **Cobalt pyrites**, $(\text{Co}, \text{Fe})\text{S}_2$ —see linnæite. **Cobalt spar**, CoCO_3 —see sphærocobaltite. **Cobaltite**, or cobalt glance, CoAsS , or $\text{CoS}_2 \cdot \text{CoAs}_2$. **Cobaltomenite**, $\text{CoSeO}_3 \cdot 2\text{H}_2\text{O}$. **Danaite** is a cobaltiferous and nickeliferous mispickel. **Earthy cobalt**—see asbolite. **Erythrite**, cobalt bloom, red cobalt, or cobalt ochre, $\text{Co}_3\text{As}_2\text{O}_8 \cdot 8\text{H}_2\text{O}$. **Ferrocobaltite**, $\text{FeAsS} \cdot n\text{CoAsS}$. **Forbesite**, $\text{H}_2(\text{Ni}, \text{Co})_2(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$. **Gersdorffite**, $(\text{Ni}, \text{Fe}, \text{Co})\text{AsS}$. **Glaucodote**, $(\text{Co}, \text{Fe})\text{AsS}$. **Grey cobalt ore**—see smaltite. **Hauchecornite**, $(\text{Ni}, \text{Co})_7(\text{S}, \text{Sb}, \text{Bi})_3$. **Hengleinite**, $(\text{Co}, \text{Ni}, \text{Fe})\text{S}_2$. **Heterogenite**, a hydrated oxide of cobalt, nickel, copper iron, or manganese. **Heubachite**, $2\text{Co}_2\text{O}_3 \cdot \text{H}_2\text{O} + \text{Co}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, or $3(\text{Co}, \text{Ni}, \text{Fe})_2\text{O}_3 \cdot 4\text{H}_2\text{O}$ —a hydrated oxide of cobalt, nickel, copper, iron, and manganese. **Jaipurite**, CoS . **Julienite**, a thiocyanate, $\text{Na}_2\text{Co}(\text{SCN})_4$. **Kerzinite**, a peat containing nickel silicate. **Keweenawite**, $(\text{Cu}, \text{Co}, \text{Ni})_2\text{As}$. **Koeltigite**, $(\text{Cu}, \text{Co}, \text{Ni})_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$. **Lavendulane**, an arsenate of cobalt and copper. **Leudouxite**, $(\text{Cu}, \text{Co}, \text{Ni})_4\text{As}$. **Linnæite**, siegenite, or cobalt pyrites, Co_3S_4 or $\text{CoS} \cdot \text{Co}_2\text{S}_3$, where the cobalt is replaced by more or less nickel—siegenite—and to some extent by iron and copper. **Lubeckite**, $4\text{CuO} \cdot \frac{1}{2}\text{Co}_2\text{O}_3 \cdot \text{Mn}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$. **Lusakite**, a cobalt bearing silicate, $8[\text{RO} \cdot \text{Al}_2\text{SiO}_5]$. **Maucherite**, $(\text{Ni}, \text{Co})_3\text{As}_2$, or $(\text{Ni}, \text{Co})_4\text{As}_3$. **Mohawkite**, $(\text{Cu}, \text{Co}, \text{Ni})_3\text{As}$. **Nickel skutterudite**, $(\text{NiCo})\text{As}_3$. **Pateraita**, an impure mineral supposed to be a cobalt molybdate. **Penroseite**, $2\text{PbSe}_2 \cdot 3\text{CuSe} \cdot 5(\text{Ni}, \text{Co})\text{Se}_2$, or $\text{PbSe} \cdot \text{Cu}_2\text{Se} \cdot 3(\text{Ni}, \text{Cu})\text{Se}_2$. **Petzite**, $(\text{Ag}_2\text{Al}_2, \text{Fe}, \text{Co})(\text{Te}, \text{As})$. **Polydymite**, $(\text{Co}, \text{Ni}, \text{Fe})_4\text{S}_6$, or $(\text{Co}, \text{Ni}, \text{Fe})_3\text{S}_4$. **Rammelsbergite**, $(\text{Ni}, \text{Co})\text{As}_2$, or $(\text{Ni}, \text{Co}, \text{Fe})\text{As}_2$. **Red cobalt**—see erythrite. **Remingtonite**, a hydrated cobalt carbonate. **Rhodalose**—see bieberite. **Roselite**, $(\text{Cu}, \text{Co}, \text{Mg})_3\text{As}_2\text{O}_8 \cdot 2\text{H}_2\text{O}$. **Safflorite**, $(\text{Fe}, \text{Co})\text{As}_2$. **Schulzenite**, $2\text{CoO} \cdot \text{Co}_2\text{O}_3 \cdot \text{CuO} \cdot 4\text{H}_2\text{O}$. **Siegenite**—see linnæite. **Saynite**—a polydymite. **Skutterudite**, CoAs_3 . **Smaltite**, or grey cobalt ore, or speiss cobalt, CoAs_2 . **Sphærocobaltite**, or cobalt spar, CoCO_3 . **Speiss cobalt**, CoAs_2 —see smaltite. **Stainerite**, $(\text{Co}, \text{Al}, \text{Fe})_2\text{O}_3 \cdot \text{H}_2\text{O}$. **Sychnodymite**, $(\text{Co}, \text{Cu})_4\text{S}_5$. **Tilkerodite**, a lead selenide. **Transvaalite**, $\text{Co}_2\text{O}_3 \cdot n\text{H}_2\text{O}$ —an oxidation product of cobalt arsenide. **Villamaninite**, $(\text{Cu}, \text{Ni}, \text{Co}, \text{Fe})(\text{S}, \text{Se})_2$. **Violarite**, $(\text{Ni}, \text{Fe}, \text{Co})_3\text{S}_4$. **Wad**—see asbolite. **Willyamite**, $\text{CoS}_2 \cdot \text{NiS}_2$. $\text{CoSb}_2 \cdot \text{NiSb}_2$, or $(\text{Co}, \text{Ni})\text{S}_2 \cdot (\text{Co}, \text{Ni})\text{Sb}_2$, or $(\text{Co}, \text{Ni})\text{SbS}$. **Winklerite**, $2\text{Co}_2\text{O}_3 \cdot \text{Ni}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ —see heterogenite.

The ores of cobalt are not abundantly distributed.⁶ The only deposits suitable for working under present economic conditions are those of Ontario, Missouri, New Caledonia, Belgian Congo, and Schneeberg. There are other deposits in Australia, Austria, Norway, and Sweden which have been worked. Those at Schneeberg, and Annaberg have been worked for 300 years, though the output is now very small. New Caledonia was the main source of the world's supply for some years preceding the opening up of the Ontario deposits, but the production there is now comparatively small. The map, Fig. 1, summarizes the geographical distribution of the principal deposits of cobalt.

Europe. In the **British Isles**,⁷ a number of small and unimportant deposits of cobalt minerals has been reported—Moel Hiraddug in Flintshire; Alderley Edge and Mottram

St. Andrews in Cheshire; Wheal Trägo, Wheal Sparnon, Wheal Huckworthy, Wheal Ann, St. Austell, Fowey Consols, and East Pool in Cornwall and Devon; Hilderstone mine in Linlithgowshire; Coille-Chraghad mine in Inverary; Tyndrum mine, Argyllshire; Alva mines of Clackmannanshire; and at Corrycharmaig, Perthshire. In France,⁸ some cobalt occurs in the silver-cobalt-nickel veins at Chalanches, Dauphiné; at Juzet, Haute-Garonne; and Sainte Marie aux Mines, Alsace. In Germany,⁹ there are lodes at Schneeberg, and Annaberg, Saxony; and at Marienberg, Erzgebirge, Wittichenau, Wolfbach, Schweina, Querbach, Giehren, Fichtegebirge, and Siegen. In Austria,¹⁰ and Germany there are deposits between Salzburg and Steiermark; in the Tyrols, etc. In Jugoslavia,¹¹ there are deposits at Aljon, Dob, and Jasikowa. In Norway,¹² there are cobaltiferous fahlbands about Skutterud and Snarum which were once the main producers of the world's cobalt, but they are not rich enough for present-day requirements. Cobaltiferous ore also occurs about Modum. In Sweden,¹³ cobaltiferous ore occurs at Gladhammer in Kalmar Län; at Vena near Vettern; at Los in Helsingland; at Tunaberg in Södermannland; and at Hakanbol in Oerebro Län. In Czechoslovakia,¹⁴ there are deposits at Joachimsthal, Bohemia; and at Dobsina, formerly in Hungary. In Italy,¹⁵ cobalt and nickel occur with the copper ores of Switzerland,¹⁶ are cobaltiferous and occur at Valais, Ryr, and Kaltenberg. In Spain,¹⁷ there are cobaltiferous ores in the valley of Gistain, Huesca; and at Guadalcanal, Andalusia. In Portugal,¹⁸ cobalt occurs in the Sierra de Cabreire. In Greece,¹⁹

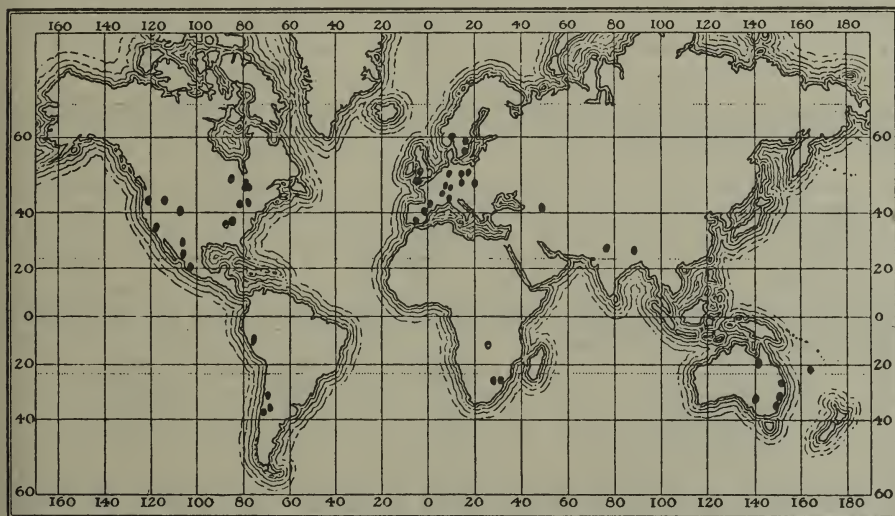

FIG. 1.—The Geographical Distribution of the World's Cobalt Deposits.

only traces of cobalt have been found in the Laurion. In Asiatic Russia,²⁰ there are abandoned workings at Dachkessan, Government of Elizabetopol, Transcaucasia. In Poland,²¹ there are deposits at Miedzianka.

Asia. In Persia,²² cobalt occurs near Täbris, Imam-radsh-David, and Anarak. In India,²³ a mixture of cobaltite and danaite, known as *sehta*, occurs at Khetri and other parts of Rajputana. Small proportions of cobalt occur near Arumanallar, Madras; and Olatura, Kalahandi State. Asbolite occurs at Henzai; erythrite in the Bawdwin mines, Burma; and Linnaite, at Sikkim. In New Caledonia,²⁴ there are deposits which supplied the major portion of the world's output before the discovery of the Canadian ore. In China,²⁵ there are deposits near Tsangscheng.

Africa. In Algeria,²⁶ cobalt ores occur near Djebel Tonila. In East Africa,²⁷ at Kenya. In Belgian Congo,²⁸ there are cobaltiferous copper ores at Katanga. In the Union of South Africa,²⁹ several deposits have been located in Transvaal—at Balmoral, Bushveld, Hartebeestfontein, and Wifontein.

North America. In Canada,³⁰ there are the well-known silver-cobalt ores about the cobalt districts, Ontario—e.g., Gowganda, Casey, Otter, Sudbury, Silver Islet; and also near Lake Wendigo, Bay Lake, Gowland Lake, and Lake Superior. There are cobaltiferous minerals east of Big Island Lake, Manitoba. In the United States,³¹ there are no large deposits, but there are some cobaltiferous ores near Fredericktown, Missouri; Marion, Kentucky; Grant Co., Prairie City, and Jackson Co., Oregon; Hill Mine, Maryland; Rock-Run, Alabama; Tanana River, Alaska; near Lowell, Massachusetts; Antony's Nose, Pennsylvania; Salina Co., Arkansas; Fort Apache, Arizona; Blackbird, Idaho; Gothic, Colorado; Los Angeles, California; and in the Goodsprings district of Nevada.

In **Mexico**,³² there are cobaltiferous minerals near Pilhuano, Jalisco; Iturbide, in Chihuahua; Guanacevi and Tamazula, in Durango; Cosala, in Sinalva; and El Boles, in Lower California.

South America. In **Argentina**,³³ cobaltiferous ore occurs at Valle Hermosa, province of La Rioja; and in the province of Catamarca. In **Chile**,³⁴ there are deposits in the province of Atacama, Coquimbo, and Aconcagua. In **Peru**,³⁵ cobalt occurs in the deposits of Rapi in Ayacucho; and at Vilcabamba in Cuzco. Small occurrences have been reported in **Bolivia**.³⁶ There are also deposits in Nueva Providencia, **Venezuela**.³⁷

Australasia. In **New South Wales**,³⁸ workable deposits occur at Carcoar, Port Macquarie, and Bungonia. There are smaller deposits in several other places. In **Queensland**,³⁹ cobaltiferous ore occurs near Selwyn; in **South Australia**,⁴⁰ at Bimbowrie near Olary; and in **Western Australia**,⁴¹ at Parkerville.

Reliable statistics for the world's output of cobalt are not available. C. W. Drury⁴² said that until 1913, the world's annual output of cobalt oxide amounted to about 250 tons, and it then increased, attaining about 400 tons in 1916. Very little, if any, cobalt metal was extracted in 1913, but in 1916, 165 tons of cobalt metal were produced. The approximate outputs of Canada and New Caledonia in tons were:

	1893	1903	1913	1923
New Caledonia	110	414	—	250
Canada	—	82	387	396

and according to the Annual Report of the mineral production of Canada for 1928, the outputs, in tons, were:

	1924	1928	1930
Canada	423·6	430·0	—
Queensland	197·2	7·7	—
Katanga	273·2	400·0	—
Chile	34·0	—	—
Germany	6·0	—	—

According to F. Ullmann, the outputs for cobalt oxide, with 70 per cent. cobalt, cobalt metal, etc., were, in tons:

	1918	1923	1926
Cobalt oxide	52·5	20·3	10·0
Cobalt metal	21·2	10·2	17·7
Mixed oxides	—	—	12·3
Cobalt compounds	—	35·4	—

The highest price per lb. for the metal in 1914 was 8s. 4d., and the lowest, 5s. 2½d.; in 1917, the highest price was 8s. 4d., and the lowest, 6s. 3d.; and in 1920, the highest price was 25s., and the lowest 12s. 6d. In 1917, the highest price for the oxide was 6s. 3d., and the lowest 4s. 2d.; and in 1920, the highest price was 17s. 1d., and the lowest, 8s. 2d.

Cobalt almost invariably accompanies nickel, so that analyses of nickel generally show the presence of some cobalt, and *vice versa*—e.g., the analyses of W. R. Barclay,⁴³ and R. J. McKay. Traces of cobalt have also been observed in numerous nickel ores—e.g., H. Laspeyres found cobalt in *beyrichite*; F. A. Genth, in *millerite*; C. W. Dickson, in *pentlandite*; W. F. Hillebrand, and G. Kalb and E. Meyer, in *bravoite*; F. A. Genth, W. F. Hillebrand, and A. Diesseldorf, in *melonite*; C. A. Winkler, in *colloidal nickel silicate*; T. L. Walker, F. Grünling, C. Palmer, and A. Rosati, in *maucherite*; K. Schlossmacher, in *niccolite*; E. Mattiolo, in *breithauptite*; D. Lovisato, in *asite*; F. von Sandberger, in *wolfachite*; H. Laspeyres, in *ballitite*; and A. Brand, in *antimonial nickel*. The analyses of the copper-nickel coinage of Bectria, 146 to 246 B.C., by W. Flight, show the presence of 0·544 per cent. of cobalt. W. Flight also observed cobalt in some old Roman bronzes; and J. Sebelien, in ancient *Egyptian and Mesopotamian bronzes*. A. Cossa in *alum* from Vulcano island; H. D. Richmond and H. Off, in *Egyptian alum*; E. D. Campbell observed cobalt in American pig-irons; J. Pattinson, C. O. Braun, H. Rössler, H. Weiske, F. Wrightson, A. Terreil, G. Lippert, M. Rubach, and O. L. Erdmann, in different kinds of *iron and steel*, and *iron ores*; H. Rössler, in *copper ores* and in

copper ; and F. N. Guild, and C. A. Münster, in *silver ores*—e.g., H. Wurtz, in *huntite* ; D. Forbes, in *arsenical silver* ; I. Domeyko, and A. L. Parsons and E. Thomson, in *proustite* ; H. Wurtz, A. L. Parsons and E. Thomson, and T. L. Walker, in *antimonial silver*, and *discracite* ; and I. Domeyko, in *naumannite*. B. Kosmann reported 0.04 per cent. of cobalt in the *brown iron ore* of Silesia ; F. J. Pope, 0.04 to 0.10 per cent. in the *magnetite* of Ontario ; C. F. Rammelsberg, G. Langhaus, S. P. de Rubies and J. Dorronsoro, L. L. Fermor, and L. G. Eakins, in various samples of *psilomelane* ; L. L. Fermor, J. L. Jarman, S. P. de Rubies and J. Dorronsoro, D. T. Day, W. Gregory, A. Völcker, and H. Rössler, up to 0.7 per cent. in *pyrolusite* ; S. P. de Rubies and J. Dorronsoro, A. Völcker, and W. Gregory, in other *manganese ores* ; J. Murray and A. F. Renard, and J. Y. Buchanan, in deep-sea *manganese nodules* ; G. Natta and M. Strada, in *spinel* ; H. Buttgenbach, in *gummite* ; A. Schöpe, in *renardite*, and in *coronetite* ; W. Campbell and C. W. Knight, C. W. Dickson, R. Beck, A. Stelzner, K. Sauer, C. F. Plattner, H. Schneiderhöhn, C. Bodewig, C. Doelter, H. Laspeyres, F. Kuhlmann, and H. Rössler, in various forms of *pyrites* ; A. Carnot, and A. Beutell, in *arsenical pyrites* ; F. von Sandberger, in *iron glance* ; K. Schulz, and T. Petersen, in *löllingite* ; C. F. Rammelsberg, P. Pilipenko, H. Peltzer, F. von Sandberger, H. A. Hillger, and T. Petersen, in *fahlerz* ; C. Zincken and C. F. Rammelsberg, in *bourbonite* ; A. Carnot, in *bismuth glance* ; C. F. Rammelsberg, in *kobellite*, and in *lillianite* ; F. A. Genth, and T. L. Walker, in *cosalite* ; R. Schneider, in *wittchenite* ; W. Skey, in *köttigite* ; F. Zambonini, in *vesbine* ; S. P. de Rubies, in *chromite*, and in native *platinum* ; F. A. Genth, and G. Frebold, in *zinc blende* ; J. J. Berzelius, F. Stromeyer, H. Rose, and G. Frebold, in *clausthalite* ; F. Heusler and H. Klinger, and F. Pisani, in *zorgite* ; C. A. Winkler, in *roselite*, and in *rhagite* ; J. J. Berzelius, in *cerite* ; A. Sachs, in *red zinc ore* ; and W. P. Headden, in a Cornish *tin* furnace ; C. A. de Gouvenain, up to 2 per cent. Co_2O_3 in the *china-clay* of Allier ; L. Azema, in *clays* from Bordes, in France, and Branchville, in Connecticut ; C. Bischof, in the *clays* of Lower Silesia. G. Bertrand and M. Mokragnatz, W. O. Robinson, J. S. MacHargue, and G. Tissandier discussed the occurrence of cobalt in *soils*. G. Bertrand and M. Mokragnatz found in two samples of arable soils, respectively 0.00028 per cent. of cobalt and 0.00136 per cent. of nickel, and 0.00037 per cent. of cobalt and 0.00174 per cent. of nickel. A. Brongniart observed cobalt in the soils near Paris ; J. Crocq, in the *sands* of Woluwe St. Lambert, near Brussels ; F. Kuhlmann, and W. E. Howarth, in coals ; K. Kraut, in the ashes of various *peats* and *lignites*, and in the *Abraum salts* of the potash works at Eime, Hannover ; A. Stelzner, in the *gneiss* of Himmelsfürst ; H. Rössler, in the *porphyry* of Imsbach ; T. Wherry, in *amethyst* ; and F. von Sandberger, in *hornblende*.

G. Torchhammer,⁴⁴ and W. Dittmar observed the presence of traces of cobalt in sea-water ; and S. S. Miholic, in mineral waters. O. Henry, N. P. Hamburg, and M. Mazade detected cobalt in the mineral waters of Nerac, and of Ronneby ; L. de Launay, in the water of Lamalou, Hérault ; F. Jaquot and E. Willm, in the water of Anjou ; R. Nasini and co-workers, in the mineral waters of Roncegno ; C. F. Eichleitner, in those of Orsola ; M. B. Hardin, in the water of Rockbridge Alum Spring, Virginia ; F. W. Clarke, in the water of the Mountain View Mine, Montana ; W. Lindgren, in the water of Cresson Spring, Pennsylvania, and of the Alleghany Springs, Montgomery Co. ; and G. F. Becker, in sinter from the waters of the steam-boat Springs, Nevada.

Cobalt has been noted to occur in traces in some living organisms. G. Forchhammer⁴⁵ observed cobalt to occur in marine algæ, and in the ashes of the oak ; T. Wherry, and J. S. MacHargue, in Kentucky blue glass—*Poa pratensis*—and in the soja-bean ; J. Roth, in the ash of the *Zostera marine* ; W. Vernadsky, in different plants ; F. B. Flinn and I. M. Inouye, in a number of plants and sea animals ; and G. Bertrand and M. Mokragnatz discussed the general occurrence of cobalt in various cryptogams and phanerogams. They found minute traces of cobalt in onions, potatoes, spinach, lettuce, cress, tomato, apricots, beans, lentils,

buckwheat, wheat, maize, rice, and mushrooms. The amounts vary from below 0.005 mgrm. to 0.30 mgrm. per kgrm. of the fresh substance. They found both nickel and cobalt in all plants examined, but in very small proportions. The relative proportions of nickel and cobalt present are roughly parallel, organs relatively rich in cobalt being correspondingly rich in nickel. The proportions are highest in the leaves, dried leaves of the following plants named containing the weight indicated (mgrm. per kgrm.) of nickel and cobalt (parenthetical figures): lettuce, 1.51 (0.054); carrot, 1.83 (0.314); spinach, 2.37 (0.74); lime, 2.50 (0.20); apricot, 3.0 (0.40); beech, 3.0 (0.35); cabbage 3.3 (0.07). Seeds or berries, after the leaves, are richest in nickel and cobalt, containing (per kgrm. of dried matter) from 0.14 to 2.25 mgrm. of cobalt in buckwheat and 0.35 mgrm. in lentils, the amount in oats being too small to be determined. The integuments of the berries are richer in nickel and cobalt than the kernels, oat bran containing 0.44 mgrm. of nickel and 0.011 mgrm. of cobalt, and wheat bran 0.39 mgrm. of nickel and 0.011 mgrm. of cobalt. The kernel of decorticated and polished rice is extremely poor in nickel and cobalt, containing only 0.02 and 0.006 mgrm., respectively, this being parallel with the poverty in manganese, zinc, and titanium already noted. Nickel and cobalt are more abundant in the bark than in the wood, beech wood containing 0.12 mgrm. of nickel and 0.01 mgrm. of cobalt and the bark 0.40 and 1.10 mgrm. respectively. The lignified shells protecting certain seeds are poor in both metals. Edible organs or parenchymatous tissues of fruits, roots, bulbs, or tubercles when dry contain moderate amounts of nickel and cobalt, the highest amount found being 3.5 mgrms. of nickel and 2.13 mgrms. of cobalt per kgrm. of dried *cantharellus cibarius*. Nickel and cobalt may act as catalysts in vegetable cells. J. S. McHargue also observed the presence of traces of nickel and cobalt in soils, animals, and plants.

H. M. Fox and H. Ramage observed the presence of cobalt in some animal tissues. The liver of the *Archidoris tuberculata* contained 0.003 per cent. of cobalt, but no nickel. Usually, the cobalt is accompanied by a high proportion of nickel. According to G. Bertrand and M. Machebœuf, cobalt occurs in all the tissues examined, excepting in certain muscles, adipose tissue, and egg-white, in all classes of animals. The organs in general contain rather more cobalt than nickel. The pancreas of all species of animals examined contain relatively large amounts of nickel and cobalt compared with the other organs. P. Dutoit and C. Zbinden also found that cobalt, nickel, and lead accumulates in the pancreas.

§ 3. The Extraction of Cobalt

The mining of cobalt necessarily varies with the nature of the deposit, and the character of the surrounding rocks. Vein deposits are mined by sinking shafts on or near the veins, and driving from the shafts along the veins. The asbolite ore of New Caledonia is a surface deposit, so that the ore is picked down after the overburden has been removed. The concentration of the ore is partly done by hand-sorting, and partly by wet-gravity, or flotation methods. Neither of these processes is available for the New Caledonia ore, but the hand-picked ore can be concentrated to a matte in a blast-furnace—this was discussed by J. S. Godard,¹ and C. S. Parsons and co-workers.

The metallurgical treatment of the complex cobalt ores involves the recovery of the contained silver, nickel, arsenic, and possibly copper. The primary consideration may be the silver, whilst the other elements are subordinate. Prior to the opening up of the Canadian deposits about 1902, nearly all the world's cobalt was produced in Europe; whilst in Europe the ores were treated for cobalt alone, in Canada, the silver, etc., are recovered. The arsenic, sulphur, copper, iron, and

nickel are associated with the ores of Europe and Canada, but those of New Caledonia contain very little sulphur and arsenic, and relatively a large proportion of manganese. The metal cobalt is not separated from the accompanying metals by dry methods, and wet methods are employed when a separation is needed.

A.—Furnace Processes

I. *Arsenical ores*.—In the extraction of cobalt oxide by smelting a mixture of the powdered arsenical ore with limestone and quartz in small blast-furnaces, there are produced (i) a cobalt, nickel, iron, and copper speiss (a regulus of arsenides) or a matte (a regulus of sulphides) containing much silver; (ii) crude silver bullion with about three-fourths of the silver contained in the ore—the remaining silver is contained in the speiss or matte and slag; (iii) a silicate slag which is rejected unless it contains over 10 ozs. of silver per ton; and (iv) a flue-dust of crude arsenious oxide which is re-sublimed and sold. The process of the extraction of the cobalt was described by R. W. Bridges.²

The speiss is crushed and ground with 20 per cent. of sodium chloride, and the mixture is roasted in a reverberatory furnace. The chloridized roast is leached with water to remove the excess of sodium chloride as well as soluble compounds of copper, nickel, and cobalt. The copper is precipitated with scrap-iron; and the cobalt and nickel are precipitated as hydrated oxides by means of sodium hydroxide. The precipitate is washed, dried, calcined, and ground. It contains about 40 per cent. cobalt, 3 per cent. nickel, and about 15 ozs. of silver per ton. The residue from the extraction of the chloridized speiss is further extracted with a soln. of sodium thiosulphate to remove silver chloride. The residue is dried, ground, and smelted with quartz to remove most of the iron as slag. The slag still contains silver and cobalt and it is re-worked in the blast-furnace with more ore. The new speiss is treated as before. The final residue is dried; heated with 20 per cent. of sodium nitrite and 10 per cent. of sodium carbonate in a reverberatory furnace. The arsenic is converted into sodium arsenate, which is extracted with hot water. The dried residue has cobalt 30.7 per cent.; nickel, 28.5 per cent.; arsenic, 1.1 per cent.; and silver, 34.6 ozs. per ton; and it is sold to the cobalt and nickel refiners. Modifications of the general method employed by other companies, etc., were described by C. W. Drury, A. A. Cole, J. de Coppet, T. H. Gant, G. M. Dyson, E. Roger, A. J. Wadhams and R. C. Stanley, C. P. Linville, S. B. Wright, F. P. Dewey, C. G. Fink, H. W. Hixon, W. Philipps, J. Savelsberg, R. Sevin, W. Borchers and F. Warlimont, D. Levat, W. Stahl, C. W. B. Natusch, O. Dyckerhoff, P. Manhès, J. Garnier, J. H. Reid, D. Lance, M. Uchino, C. Schreiber, W. Langguth, P. Louyet, O. Barth, C. Guillemain, V. Tafel, F. J. G. Beltzer, H. B. H. Hallowell, W. A. Dixon, and H. Herrenschildt and M. Constable.

At Deloro, Canada, the crushed ore is mixed with the necessary fluxes in a pug-mill and smelted in a blast-furnace for slag, speiss, and crude silver bottoms. The crushed speiss is calcined with a chloridizing roast. The roasted product is extracted with a soln. of sodium cyanide, and the silver precipitated by aluminium dust. The crude silver bottoms from the blast-furnace are heated in an oxidizing atm., whereby the impurities are oxidized and largely eliminated. The silver is further refined by mixing it with the precipitated silver from the cyanide soln., and it is fused with nitre and borax, and cast into bars. The arsenic is recovered as arsenic trioxide in the flues and bag houses connected with the blast-furnace, and when a high degree of purity is desired, it is re-sublimed.

In F. Wöhler's old process for the extraction of cobalt from arsenical ores like smaltite, skutterudite, and cobaltite, 1 part of the powdered ore is fused with 3 parts of potassium carbonate, and 3 parts of sulphur. The cold mass is extracted with water to remove potassium sulphoarsenate; impure cobalt sulphide remains. The treatment with alkali carbonate and sulphur is repeated to remove the arsenic, and there remains cobalt sulphide mixed with the sulphides of nickel, iron, lead, copper, and bismuth. These sulphides are converted into sulphates by treatment

with nitric acid, or by roasting. The acidulated soln. is then treated with hydrogen sulphide to precipitate the sulphides of lead, copper, and bismuth, and the boiling filtrate is treated with nitric acid and calcium carbonate to precipitate a basic salt of iron. The cobalt and nickel sulphates remain in soln. C. G. Richardson roasted the ore with sodium sulphide, or sulphate, or other sulphates—*e.g.*, N. H. M. Dekker used magnesium sulphate, $4\text{CoAs}_2 + 5(\text{MgSO}_4 \cdot 4\text{H}_2\text{SO}_4) = 4\text{As}_2\text{O}_3 + 4\text{CoSO}_4 + 5\text{MgSO}_4 + 20\text{H}_2\text{O} + 16\text{SO}_2$. Modifications were described by J. von Liebig, A. Duflos, L. Thompson, L. A. Pélatan, J. W. Neill, H. Herrenschmidt and M. Constable, W. de Witt, N. V. Hybinette, W. Wright, S. F. Hermbstädt, P. Papencordt, O. Dyckerhoff, and H. A. Lewis and F. G. Price. The arsenical ore can also be treated with chlorine fractionally to sublime different chlorides as in the processes of A. L. D. d'Adrian, W. H. Dyson and L. Aitchison, H. T. Kalmus, W. Mc. A. Johnson, and the Metallurgical Development Corporation; W. A. Dixon, and H. A. Megraw heated the arsenical ore to redness in hydrogen chloride to volatilize the arsenic (and zinc) as chlorides, and extracting the mass with water or other solvent. P. M. McKenna tried heating the speiss with boric oxide. J. H. Reid heated the speiss in a vacuum arc-furnace to volatilize fractionally first the sulphur, then the arsenic, then the silver chloride, and finally, at 3000° , the nickel and cobalt. C. G. Fink heated the speiss with calcium carbonate and carbide in an electric vacuum furnace and observed the reaction symbolized: $2\text{CaO} + \text{CaC}_2 + \text{CoAs}_2 = 2\text{CO} + \text{Ca}_3\text{As}_2 + \text{Co}$.

II. *Sulphide ores*.—The ore is desulphurized by smelting in a shaft-kiln, and then heating by a blast in a converter, and treating the product as an oxidized ore—*vide infra*. The ore can be heated with silica or silicates, as described by W. Wanjukoff; smelted with polysulphides, or sulphates, carbon and silica, as indicated by R. W. E. McIvor, and J. E. Harding; bessemerized with limestone, as discussed by P. Manhés, N. V. Hybinette, V. Tafel, A. Bremshorst, P. C. Gildchrist and S. G. Thomas, A. Vogt, and J. Savelsberg; or smelted with barium sulphate and silica, as indicated by C. Künzel. P. Manhés used boracite, and B. Bogitsch, sodium sulphate, to facilitate the formation of a slag. There are also processes involving sulphate-roasting, in which sulphates or basic sulphates are found and subsequently leached out with water or dil. acid. They were discussed by W. Borchers and co-workers, O. Barth, R. W. E. McIvor, F. O. Kichline, M. B. Pécourt, Meyer Mineral Separation Co., A. E. Smail, and W. N. Hartley and W. E. B. Blenkinsop. J. A. McLarty oxidized the sulphide ores by heating them in steam under press. E. E. Naef heated the ore mixed with alkali chloride, sulphate, or sulphide, and calcium carbonate, with or without the addition of carbon, in hydrogen and obtained the metal. The Compagnie Electrometallurgique heated the sulphide ore in a resistance furnace between iron electrodes to form iron sulphide and cobalt. P. Manhés heated the sulphide ore with calcium oxide, and chloride or bleaching powder. A. Bremshorst heated the sulphide ore with a mixture of carbon and sodium sulphate, and at 1300° the sulphides of the foreign metals form a mobile liquid which can be poured off the cobalt sulphide. The latter can then be reduced to metal by heating it with carbon. J. Swinburne and E. A. Ashcroft heated the sulphide ore in a converter, treated the product with a molten chloride and chlorine or sulphur monochloride, and then again heated it in a converter, and removed the iron manganese chlorides by volatilization in chlorine. W. McA. Johnson employed a modification of the process.

III. *Oxidized and silicate ores*.—Processes have been devised for treating roasted ores, and oxides, and silicate ores. W. Stahl, and W. Wanjukoff melted the ore with suitable additions to cause the iron to pass into the slag as a silicate or ferrite, and to leave the cobalt and nickel compounds behind. Cobalt is extracted from the copper ores of Katanga by heating them with a little carbon so that only a partial reduction occurs. Most of the copper is reduced to metal, and the cobalt remains with the slag. The slag is then mixed with lime and carbon, and heated

electrically. This produces an alloy of cobalt, copper, iron, and silicon in the respective percentage proportions 30, 26, 40, and 0.7. When a layer rich in cobalt is treated with dil. sulphuric acid, the iron and cobalt pass into soln.—most of the copper remains undissolved. Details were discussed by L. Detrez, and F. Kroll. J. W. Moffat heated the ore with carbon monoxide without fusion, and afterwards melted the metal in an electric furnace. B. Bogitsch heated the ore with carbon and lime. O. Barth melted the ore with carbon, and calcium sulphate. Modifications were described by H. Herrenschmidt and E. Capelle, O. Massenez, W. Mathesius, J. H. Reid, J. Savelsberg, and P. Schwalb. O. Barth heated the oxidized ore in a current of sulphur dioxide and air to convert the cobalt into sulphate and enable it to be leached out with water. Modifications of the process were made by J. G. and C. J. G. Aarts, F. A. Eustis, and W. Savelsberg. C. W. B. Natusch, W. Schöneis, and W. Stahl subjected the oxidized ore to a chloridizing roast and extracted the cobalt chloride with water.

B.—*Leaching Processes*

S. F. Hermbstädt, and P. Berthier opened the ore by fusion with potassium nitrate; T. Barton and T. B. McGhie, by fusion with sodium carbonate; P. M. McKenna, by fusion of the speiss with boric acid when the heavier nickel speiss separates from the lighter cobalt borate slag; and A. Patera fused a mixture of the roasted ore with calcium, sodium, and potassium nitrates. Some of the cobalt minerals can be opened up by digestion in nitric acid, or in dil. sulphuric or hydrochloric acid mixed with nitric acid. The nitric acid is not needed for earthy cobalt. The roasted ore is more difficult to dissolve than the raw ore. P. Louyet, G. A. Quesneville, A. Patera, B. M. Tassaert, F. Claudet, W. de Witt, and A. Laugier, for example, dissolved the roasted ore in nitric acid; W. McA. Johnson, O. Barth, A. J. Wadhams and R. C. Stanley, F. J. G. Beltzer, A. Drouin, J. de Coppet, H. Lundberg, and A. Carnot, in conc. hydrochloric acid; H. Rosalt, hydrochloric acid and ozonized air; L. J. G. de Burlet, V. N. Hybinette, F. Borchers, O. Barth, C. von Hauer, J. de Coppet, W. Borchers, D. Lance, H. A. Frasc, E. Schulze, M. J. Udy and A. C. Ralston, A. J. Wadhams and R. C. Stanley, and W. Phillips, sulphuric acid; J. B. Readman, sodium sulphate and sulphuric acid; J. von Liebig, and W. Borchers, potassium or sodium hydrosulphate; F. J. C. Beltzer, sodium hydrosulphate and sulphuric acid; F. Gautier, hydrochloric and sulphuric acids; M. Dixon and M. Ratte, sulphurous acid; R. W. E. McIvor, a soln. of magnesium chloride under press.; C. Gabrielli, a soln. of a ferric salt in air; C. W. Drury, a soln. of ferric chloride or sulphate; and H. N. Warren, a hydrochloric acid soln. of copper nitrate. The soln. obtained by extracting the ore with acids can be treated with an excess of ammonia. When the ammoniacal soln. is heated, oxides are precipitated approximately in the order: zinc, cadmium, cobalt, nickel, copper, and silver. Processes based on these reactions were described by H. Caron, C. Gabrielli, D. Lance, M. Malzac, L. Schlecht and co-workers, and V. Varlez.

Speiss, and regulus can be dissolved by making them the anode in an electrolytic cell. In C. C. Cito's method for extracting cobalt and nickel, the ore is treated with copper and fluxes in a reverberatory furnace. An alloy of copper, silver, nickel, cobalt, and arsenic is formed along with a slag. The alloy is cast in anode moulds, and used as anodes in a bath of copper sulphate with sheet-copper cathodes. The copper is deposited on the cathodes, the silver is precipitated as slime, the cobalt and nickel remain in soln., and the arsenic occurs partly in the anode slime, and partly in soln. G. Vortmann based a process on the assumption that if a current be passed through a soln. of nickel and cobalt containing no alkali sulphates or other neutral alkali salts, cobaltous and nickelous hydroxides or basic salts are deposited on the cathode during electrolysis. If the current is reversed, the nickelous hydroxide or basic salt dissolves, whilst cobaltous hydroxide is oxidized to hydrated cobaltic oxide. On repeating the operation a number of times, all the

cobalt can be obtained as hydrated cobaltic oxide, whilst the nickel remains in soln. If a small proportion of a chloride be present in the liquid, the cobaltous hydroxide is converted to cobaltic hydroxide without changing the direction of the current. The separation of cobalt is facilitated by warming. When the precipitation is complete, the current is stopped, and the liquor heated to 60° or 70° whereby a small quantity of nickelous hydroxide remaining with the cobaltic oxide is dissolved. The nickel in soln. is free from cobalt. H. S. Guiterman extracted cobalt by the electrolysis of a soln. of nickel and cobalt chlorides. The chlorine liberated at the anode reacts with the electrolyte to form hydrated cobaltic oxide and free acid. To prevent the electrolyte becoming too acidic, and then dissolving some cobaltic hydroxide, some sodium carbonate is added. Electrolytic processes were also devised by L. J. G. de Burlet, H. H. A. and W. W. Wiggin and A. S. Johnstone, E. E. Armstrong, G. A. le Roy, A. Coehn and E. Salomon, E. Günther, C. L. Mayer, W. Kaiser, L. Münzing, H. A. Frasch, and N. H. M. Del'ker.

In H. Herrenschmidt and M. Constable's process, the powdered wad is made into a thin paste with a soln. of ferrous sulphate, and boiled. Cobalt, nickel, and manganese sulphates pass into soln., whilst iron oxide, silica, and alumina remain as a residue: $2\text{FeSO}_4 + \text{MnO}_2\text{CoO} = \text{Fe}_2\text{O}_3 + \text{MnSO}_4 + \text{CoSO}_4$; and $2\text{FeSO}_4 + \text{Co}_2\text{O}_3 = \text{Fe}_2\text{O}_3 + 2\text{CoSO}_4$. Sodium sulphide is added to the filtered soln. to precipitate the cobalt, nickel, and manganese as sulphides. A soln. of ferric chloride is now added, and this oxidizes the manganese sulphide to sulphate, which passes into soln.; the cobalt and nickel sulphides are washed, converted into soluble sulphates by roasting, and extracted with water. The sulphates are converted into chlorides by calcium chloride. A fraction of the chloride soln. is treated with milk of lime, and the insoluble cobaltous and nickelous hydroxides which are precipitated are oxidized by chlorine. The washed precipitate is introduced into the remainder of the chlorine soln., stirred, and heated. Black hydrated nickel oxide passes into soln. whilst the cobalt in soln. is precipitated. The result is a soln. of nickel chloride with a suspension of hydrated cobaltic oxide. The latter is separated by filtration, washed, and ignited.

The soln. of cobalt salt associated with salts of other metals has to be treated to isolate the cobalt salt. The process employed depends on the nature of the associated metals, and the solvent. O. Barth said that with sulphuric acid as solvent, lead will be wholly precipitated as sulphate, and that antimony will be precipitated almost completely, and three-fourths of the arsenic as a basic iron salt. Hydrochloric acid soln. will deposit much of the lead as lead chloride, antimony as basic chloride, and antimony and arsenic as basic iron salts.

E. Sack added lead dioxide to a soln. of cobalt, manganese, iron, lead, and aluminium salts and found that all but the cobalt were precipitated. P. Louyet found that iron can be precipitated from a soln. of cobalt and nickel salts, by additions of cobalt hydroxide. T. M. Careis treated a hydrochloric acid soln. of the metals with sodium hydroxide, and dissolved the precipitate in sulphuric acid. The soln. was neutralized with alkali to precipitate copper, iron, and other metals. The cobalt and nickel remaining in soln. were treated with hot ammonium or potassium sulphide to precipitate the nickel. The cobalt was precipitated by zinc as recommended by H. Grosse-Bohle. T. Watanabe described the recovery of 0.05 to 1.0 per cent. of cobalt from cupriferous pyrites.

Processes for separating salts of foreign metals from the soln. of cobalt salts were suggested by C. H. Aaron, E. F. Anthon, C. F. Bucholz, J. M. Carew, H. Caron, R. S. Carreras, W. A. Dixon, M. Dixon and M. Ratte, J. B. du Faur, H. A. Frasch, J. T. Carrick and B. St. Pattison, C. von Girsawald and co-workers, H. Grothe, J. O. Handy, S. S. Hanes, H. Herrenschmidt, H. Herrenschmidt and E. Capelle, H. Hirtz, C. Hoepfner, W. McA. Johnson, J. P. A. Larson and G. K. L. Helme, A. Laugier, D. M. Liddell, W. Malzac, Metallurgical Development Corporation, Metals Extraction Corporation, Orkla Grube Aktiebolaget, M. B. Pécourt, H. Pederson, G. Perry, the Rhodesia Broken Hill Development Co., H. Rosalt, E. Sack, C. F. Schantz, G. Schreiber, La Société Anonyme des Établissements Malétra, S. P. L. Sörenson, F. A. Sperry, W. Stahl, A. Taraud and

co-workers, J. H. Thwaites, J. H. Thwaites and S. J. Ralph, M. J. Udy and O. C. Ralston, A. J. Wadhams and R. C. Stanley, H. N. Warren, A. Weissenborn, H. H. A. and W. W. Wiggins and A. S. Johnstone, C. Winkelblech, and G. C. Wittstein.

§ 4. The Separation of Cobalt and Nickel

Many processes have been proposed for the separation of cobalt and nickel for analytical purposes, and for preparing nickel and cobalt of a high degree of purity. Only a few are suited to give good, clean separations. Some are rough separations where extreme purification is not usually so important. The subject was discussed by R. Fischer,¹ F. Gauhe, and C. Krauss.

(i) A. Laugier digested the mixed precipitate of cobalt, nickel and iron hydroxides with an excess of a soln. of oxalic acid, and removed the soluble iron oxalate by filtration and washing. The insoluble oxalates were dissolved in ammonia, and on exposing the filtered soln. to air for several days ammonium nickel oxalate and manganese oxalate were deposited, whilst cobalt oxalate above remained in soln. F. Stromeyer, P. Louyet, E. F. Anthon, W. de Witt, C. Winkelblech, C. Künzel, and G. A. Quesneville used modifications of this process. A. Carnot said that when a soln. containing alkali or ammonium oxalate, is treated with

ammonium sulphide, nickel remains in soln. as a sulpho-salt, but the cobalt is precipitated as sulphide.

(ii) According to R. Phillips, and G. C. Wittstein, if a soln. of the two oxides in an excess of acid is supersaturated with ammonia, diluted with air-free water, and treated with potassium hydroxide, nickel oxide is first precipitated, and the cobalt remains in the filtrate. J. J. Berzelius added that, if air-free water is not employed or if the liquor after treatment with potash-lye is exposed to air, cobaltic oxide is precipitated along with the nickel oxide.

(iii) J. Persoz separated the two oxides by dissolving them in hydrochloric or nitric acid, saturating the soln. with phosphoric acid, adding ammonia until the precipitate first produced is re-dissolved, and exposing the soln. to air. The phosphate precipitation process in the presence of acetic acid was examined by M. S. Cheney and E. S. Richards, J. Hope, J. Persoz, T. H. Henry, G. Schreiber, G. Perry, S. P. L. Sörensen, P. Dirvell, and H. Baubigny.

(iv) T. Barton and T. B. McGhie proposed separating the two chlorides by the fractional crystallization of the slightly acidified chloride soln.; R. S. Carreras, by the fractional crystallization of the sulphates; and J. H. Reid, by the fractional precipitation of the orthophosphate.

(v) J. B. Richter separated the two salts by crystallization from a soln. containing a large quantity of ammonium sulphate.

(vi) C. F. Bucholz, and D. Lance proposed separating cobalt and nickel oxides by fractional precipitation with ammonia, or by dissolving the oxides in ammonia after precipitation. F. Pisani also described a modification of the process.

(vii) J. L. Proust treated a soln. of the two oxides in sulphuric acid with potassium hydroxide, and found that the less soluble potassium nickel sulphate separates out first, but several repetitions of the process are necessary.

(viii) J. von Liebig found that potassium nickel cyanide is decomposed by acids under conditions where the corresponding cobalt salt is not decomposed. Hence, potassium cyanide is added to an acidulated soln. of the two metals until the precipitate re-dissolves. The soln. is gently heated, and after cooling, it is treated with dil. sulphuric acid and filtered. The filtrate is treated with nitre, evaporated, and ignited for cobaltic oxide. The precipitate is decomposed by potassium hydroxide or carbonate into soluble potassium cobalt cyanide, and insoluble nickel hydroxide or carbonate. J. von Liebig, and T. H. Henry found that this process is not quite satisfactory because the nickel always contains some cobalt.

J. von Liebig obtained satisfactory results by modifying the process. The mixed oxides are treated first with hydrocyanic acid, and then with potash-lye, and the liquid is warmed till all is dissolved. The soln. is boiled to expel hydrocyanic acid, and the potassium cobaltous cyanide is converted into potassium cobaltic cyanide by chlorine or bromine, whilst the nickel remains in soln. as a complex cyanide. Finely-powdered mercuric oxide is added to the warm soln. to precipitate the nickel partly as oxide and partly as cyanide. The ignition of the washed precipitate furnishes nickel free from cobalt. The filtrate is supersaturated with acetic acid, and the boiling soln. is treated with cupric sulphate, whereby copper cobalt cyanide is precipitated. The precipitate becomes granular if the mixture is boiled for some time. It is then filtered, washed, and dissolved in hydrochloric acid. The soln. is treated with a little nitric acid, then with hydrogen sulphide. The filtrate is boiled for a moment to expel the hydrogen sulphide, treated with boiling potassium hydroxide, and the precipitated cobalt hydroxide is well washed, dried, and ignited for cobaltic oxide free from nickel.

The process was discussed by A. Carnot, E. Fleischer, O. W. Gibbs, F. Wöhler, F. Gauhe, A. Guyard and H. Tamm, J. F. Hambly, A. Jorissen, H. Kämmerer, A. Kläye and A. Deus, L. L. de Koninck, C. H. John, W. E. Pawlow, J. S. C. Wells and H. T. Vulté, and C. Zimmermann. H. Fleck, and A. Guyard observed that when the ammonium sulphide precipitate is treated with a soln. of potassium cyanide, only the nickel passes into soln. J. A. Sanchez found that the cobalt is precipitated from a cyanide soln. by silver nitrate, the nickel remains in soln.

(ix) H. Rose treated a hydrochloric acid soln. of the mixed oxides with chlorine

to form cobaltic chloride. The soln. is then treated with an excess of barium carbonate and allowed to stand in the cold for about 18 hrs. with frequent agitation. The precipitated cobaltic oxide mixed with the excess of barium carbonate is dissolved in hot hydrochloric acid. The barium is removed as sulphate, and the cobalt precipitated by potassium hydroxide. The filtrate containing nickel and barium chlorides is similarly treated to remove the barium as sulphate, and then the nickel as hydroxide. The process was examined by J. D. Smith, T. H. Henry, T. Fleitmann, E. Donath, T. Moore, and R. L. Taylor.

(x) F. Claudet added ammonium chloride to a nitric acid soln. of the mixed oxides, saturated the liquor with ammonia, and agitated it with air or oxygen and boiled with an excess of hydrochloric acid, whereby cobalt purpureochloride, $[\text{CoCl}(\text{NH}_3)_5]\text{Cl}_2$, is precipitated. The method was recommended by S. P. L. Sørensen, and H. Copaux as a useful process for preparing pure cobalt; and T. W. Richards and G. P. Baxter employed the process for purifying cobalt for their at. wt. determinations. Modifications were described by R. Phillips, W. de Witt, H. A. Frasch, G. T. Morgan and J. D. M. Smith, G. Schuster, H. Grothe, and H. Rose. S. P. L. Sørensen's directions are :

The carbonate—say 20 grms.—is dissolved in the smallest quantity of hydrochloric acid (1 : 1); and to the filtered and cooled soln. is added a mixture of 250 c.c. of conc. aq. ammonia, and 50 grms. of ammonium carbonate dissolved in 250 c.c. of water. A current of air is passed through the liquid for 3 hrs. The soln. is now mixed with 150 grms. of ammonium chloride, and evaporated on a water-bath for a couple of hours, when a mush is produced. This is stirred up with dil. hydrochloric acid. If any carbon dioxide is developed, the liquid is slightly over-saturated with ammonia by adding 10 c.c. of the conc. aq. soln. The 400 to 500 c.c. of liquid are heated for an hour on the water-bath; 300 c.c. of conc. hydrochloric acid are added, and all is warmed on a water-bath for half to three-quarters of an hour. The ammine salt is then filtered from the cold liquid; washed with hydrochloric acid (1 : 1) until freed from ammonium chloride; and then washed with alcohol until freed from acid. The yield is 3.45 grms. The salt can be re-crystallized by dissolution in about 400 c.c. of 2 per cent. aq. ammonia, filtered, and then mixed with 300 c.c. of conc. hydrochloric acid, etc., as before. The yield is now 33 grms. The salt can be reduced to cobalt by heating it in a stream of hydrogen; it can be converted into oxide by fusion with sodium carbonate, or by heating it with nitric acid, evaporating the soln. to dryness, and heating the product until nitrogen oxides are no longer evolved.

(xi) A process has been devised which is based on the reaction discovered by N. W. Fischer, that when potassium nitrite is added to an acetic acid soln. of a cobalt salt, potassium nitritocobaltate is precipitated, whilst nickel does not yield an insoluble salt under these conditions. Observations on this subject were made by A. Stromeyer, W. de Witt, V. Dreyer and A. Richter, H. Pützer, H. Nitze, O. W. Gibbs and F. A. Genth, A. Duflos and N. W. Fischer, O. Brunck, E. Murmann, O. Köttig, B. Brauner, H. Rose, O. L. Erdmann, F. Gauhe, A. Streng, H. Baubigny, J. B. Mackintosh, T. Fleitmann, S. R. Benedict, H. Bötticher, and H. Copaux. T. W. Richards and G. P. Baxter employed the process in purifying cobalt for their at. wt. determinations.

(xii) According to M. Ilinsky and G. von Knorre, if a soln. of nitroso- β -naphthol be added to a mixed soln. of cobalt and nickel salts, a bulky precipitate of the cobalt salt is produced, whereas nickel gives no such precipitate. The process is used for separating small amounts of cobalt from large amounts of nickel; it was examined by R. Fischer, H. Copaux, C. Krauss, L. L. de Koninck, R. Burgess, A. Eder, P. Ślawik, K. Wagenmann, L. A. Congdon and T. H. Chen, F. G. Germuth, W. H. Chapin, and C. Meineke.

(xiii) O. Brunck observed that if an excess of α -dimethylglyoxime be added to a strongly ammoniacal soln. of cobalt and nickel salts, the nickel salt alone gave a precipitate of the complex salt. The process is useful for separating a small proportion of nickel from a large proportion of cobalt; it was examined by L. Tschugaeff, K. Kraut, A. Ivanicky, H. Wdowiszewsky, F. Feigl and H. J. Kapulitzas, F. G. Germuth, V. Cuvelier, A. R. Middleton and H. L. Miller,

P. Bogoluboff, L. V. W. Spring, F. Ibbotson, H. Pederson, and S. W. Parr and J. M. Lindgren.

(xiv) H. Grossmann and co-workers found that dicyanodiamidine sulphate likewise precipitates relatively small proportions of nickel from large proportions of cobalt.

(xv) R. Fischer, and A. Carnot obtained an imperfect separation of cobaltic oxide by adding hydrogen dioxide to the cold soln. of nickel and cobalt salts either before or after saturation with ammonia. The separation is not complete. A. Carnot found that if hydrogen dioxide, ammonium chloride, and ammonia is added to a mixed soln. of cobalt and nickel salts, and the soln. is treated with ammonium molybdate and an excess of acetic acid, a bulky, rose-coloured precipitate of cobalt molybdate is formed, which, when heated to redness, has the composition $2\text{CoO} \cdot 7\text{MoO}_3$.

(xvi) E. Sack, J. D. Smith, and W. J. Harshaw treated the soln. of sulphate with the calculated quantity of lead dioxide when hydrated cobalt oxide is precipitated, and nickel sulphate remains in soln.

(xvii) A. Coehn and E. Salomon found that hydrated cobalt oxide is precipitated by the addition of a persulphate, say ammonium persulphate, to the soln., and nickel salt remains in soln.

(xviii) According to P. Louyet, and A. Patera, if bleaching powder is added to a mixed soln. of the salts, manganese peroxide is first precipitated, then cobaltic oxide, and lastly nickel. The process, using as oxidizing agents, sodium or calcium hypochlorite, sodium hypobromite, potassium hydroxide and bromine, or sodium hypochlorite and ammonia, was applied by T. Fleitmann, E. Donath, A. Carnot, J. Bernard, T. H. Gant, C. von Hauer, G. Schreiber, A. von Kripp, W. McA. Johnson, G. Selve, O. Barth, F. H. Rhodes and H. J. Hosking, M. J. Udy and O. C. Ralston, E. J. Mills and J. J. Smith, O. W. Gibbs, G. Delvaux, R. L. Taylor, H. Rose, O. Popp, T. H. Henry, O. C. Ralston, C. W. Drury, H. N. Warren, K. S. Guiterman, P. Berthier, G. Vortmann, A. Terreil, C. Krauss, and A. Jorissen. Modifications in which, say, chlorine is passed into alkali-lye in the presence of the mixed hydrated oxides, were described by W. A. Dixon, H. Herrenschildt, and La Société Anonyme des Établissements Malétra.

In applying the process, the mixed oxide is dissolved in hydrochloric acid. Powdered calcium carbonate is added to the warm liquor gradually, with stirring, until no further precipitate is obtained. The precipitate of iron, arsenic, and silica is removed by filtration, and the soln. is treated with bleaching powder added slowly, with stirring, until nearly all the cobalt is precipitated as black oxide. Very little nickel is precipitated. The washed and dried precipitate is calcined for cobalt oxide. The oxide is boiled with a soln. of sodium carbonate to convert calcium sulphate to carbonate. The precipitate is washed with dil. hydrochloric acid, then with water, and finally dried and calcined. According to H. T. Kalmus, the initial and final products of this treatment had the composition :

	Co	Ni	Fe	S	As	SiO ₂	Ca
Crude oxide . . .	70.36	1.12	0.82	0.45	0.10	0.20	0.50
Purified oxide . . .	71.99	0.041	0.11	0.02	none	none	0.02

(xix) A. Rosenheim and E. Huldshinsky treated the soln. of mixed salts with an excess of ammonium thiocyanate, and extracted the cobalt salt by a mixture of amyl alcohol and ether (1 : 25). The nickel salt remains in the aq. layer. The process was discussed by W. Skey, C. H. Wolf, H. W. Vogel, M. Pritze, A. D. Powell, and H. Grossmann.

(xx) E. Pinerua, J. Renner, and F. S. Havens found that whilst cobalt chloride is readily soluble in ether saturated with hydrogen chloride, nickel chloride when similarly treated gives a yellow precipitate.

(xxi) L. Mond based a process for the separation of nickel on the fact that nickel readily combines with carbon monoxide at 50° to 80° to form a volatile carbonyl which decomposes at a higher temp., whilst cobalt under similar conditions does not form a carbonyl. The process was discussed by W. Singleton, and W. C. Roberts-Austen.

(xxii) H. Delfs found that if insufficient sodium acetate for complete decomposition be added to a soln. of cobalt and nickel nitrates, and the liquid treated with hydrogen sulphide, cobalt is precipitated free from nickel, or nickel free from cobalt, according to the proportion of sodium acetate employed.

(xxiii) J. H. Vivian thought that it would be possible to separate cobalt and nickel by taking advantage of the different affinities of the two elements for arsenic.

(xxiv) T. L. Phipson, L. Compin, W. Singleton, E. Cattelain, A. Whitby and J. P. Beardwood, and E. D. Campbell found that potassium xanthate precipitates both cobalt and nickel xanthates; when a few drops of ammonia are added, the nickel passes into soln. whilst the cobalt xanthate can be collected on filter-paper.

(xxv) W. R. Omdorff and M. L. Nichols found that cobalt in neutral soln. is precipitated by dinitrosoresorcin, and that it can be thus separated from a small proportion of nickel.

(xxvi) A. Carnot proposed separating small proportions of nickel from cobalt by adding ammonium molybdate to a soln. containing an excess of ammonium chloride, ammonia, and hydrogen dioxide. Cobalt molybdate is precipitated. L. A. Congdon and T. H. Chen did not obtain good results, owing to the difficulty of adding the exact amount of ammonium molybdate required for the purpose.

(xxvii) The fractional precipitation of cobalt as ammonium cobalt phosphate and weighing as cobalt pyrophosphate has been discussed by J. Clark, L. A. Congdon and T. H. Chen, H. D. Dakin, J. Dick, P. Dirvell, J. Hope, R. Strebing and J. Pollak, C. S. Tatlock, and H. H. Willard and D. Hall.

(xxviii) P. Gucci evaporated a soln. of the two metals to dryness, heated the residue in molten potassium nitrate, extracted the mass with hot water, and extracted the nickel from the residue by dil. nitric acid. C. Krauss said that the separation is incomplete.

(xxix) E. A. Demarçay observed that when an ammoniacal soln. is treated with zinc, the nickel is precipitated before the cobalt.

(xxx) L. Thompson treated with ammonium carbonate a soln. containing ammonium chloride and found that the nickel remains in soln. and the cobalt is precipitated. C. Winkler said that the separation is qualitative and not quantitative.

(xxxi) K. Flick based a process on the fractional decomposition of the sulphates by heat.

J. V. Dubsy and V. Dostal studied the purification of cobalt salts from nickel through the formation of complex amines. Methods for the separation of cobalt and nickel electrolytically in analytical work, etc., have been proposed by E. Basse and G. Selve,² W. J. Harshaw, R. L. Suhl and co-workers, W. D. Bancroft, C. A. Kohn and J. Woodgate, J. E. Root, G. Vortmann, A. Coehn and E. Salomon, A. Coehn and M. Gläser, A. Classen, D. Balachowsky, E. F. Smith, S. A. Pleteneff and W. W. Kusnezowa, and H. H. Alvarez. In the opinion of B. Neumann, F. M. Perkin, E. F. Smith, O. P. Watts, and P. Bruylants, the proposed methods are not satisfactory. P. Röntgen and R. Buchkremer discussed the effect of cobalt in zinc electrolytes in reducing the yield.

There are some monographs and textbooks dealing with the metallurgy of cobalt. For instance:

L. Ouvrard, *Industries du Chrom, du manganese, du nickel, et du cobalt*, Paris, 1910; E. Prost, *Cours de métallurgie des métaux autres que le fer*, Paris, 1912; C. Schnabel, *Handbuch der Metallhüttenkunde*, Berlin, 1904; London, 2. 753, 1907; C. W. Drury, *Cobalt—its Occurrence, Metallurgy, Uses and Alloys*, Toronto, 1919; H. Herrenschmidt and E. Capelle, *Le cobalt et le nickel*, Rouen, 1885; M. Fourment and L. Guillet, *Métallurgies du plomb du nickel et du cobalt et alliages de ces métaux*, Paris, 1926; H. § 5. The Preparation of Metallic Cobalt

Cobalt is fairly readily reduced from its compounds. According to E. D. Clarke,¹ cobalt oxide is reduced to the metal in the oxyhydrogen flame. F. O. C. Gren, W. A. Lampadius, W. Hankel, B. M. Tassaert, P. Berthier, G. Selve and F. Lotter,

H. T. Kalmus, and H. Moissan found that the oxide is reduced by heating it in a carbon crucible, or by heating it when admixed with carbon or starch. C. Winkler heated a mixture of cobaltous oxide and 10 to 12 per cent. of starch or wheat meal, covered with pieces of charcoal, in a porcelain crucible at a white-heat for an hour. There is formed a spongy metal which can easily be crushed to powder; if the heat be too intense, the metal appears in thick plates. To remove carbon from the metal, the product can be mixed with 25 to 30 per cent. of cobalt oxide, and melted. L. Thompson reduced the oxide by potassium tartrate in a carbon crucible, and the product containing about 4 per cent. of carbon was then melted with cobalt oxide and borax in a crucible lined with alumina. H. Moissan, and D. M. Liddell reduced the metal in an electric furnace. H. T. Kalmus said that the reduction of cobalt oxide by anthracite required 1 hour at 1200° for complete reduction under conditions where with charcoal, or lampblack, the reduction is completed in 1 hour at 900° , and in 10 minutes at 1000° to 1100° . About 20–30 per cent. more carbon was employed than corresponds with the equation: $2\text{Co}_3\text{O}_4 + 4\text{C} = 6\text{Co} + 4\text{CO}_2$. The application to industrial processes was discussed by A. L. D. d'Adrian, L. P. Basset, and S. B. Wright. B. Bogitch investigated the reduction of cobalt oxide by carbon monoxide, wood-charcoal, and coal. If the temp. is high enough for the slag to separate, the degree of reduction is independent of the proportion of reducing agent present. The rapid fusion of the oxide ore prevents a state of equilibrium between the ore and the reducing agent being established. C. G. Fink used calcium carbide as reducing agent. J. J. Berzelius, J. W. Döbereiner, H. St. C. Deville, and R. Schneider reduced cobalt oxalate to metal by heating it to redness; and, according to H. Moissan, cobalt oxide begins to be reduced by carbon monoxide at about 300° ; and H. T. Kalmus found that between 500° and 750° , over 90 per cent. of cobaltous oxide is reduced by carbon monoxide in a few minutes, but the remainder is reduced very slowly at that temp.; between 750° and 900° , the part that is not reduced in the first few minutes is smaller the higher is the temp. At 900° , about 98.8 per cent. is reduced in the first few minutes. At low temp., say between 350° and 450° , the finely-divided metal acts on the carbon monoxide with the separation of carbon. The subject was studied by B. Bogitch, L. Mond and co-workers, the Farbenindustrie Aktien Gesellschaft, and the Badische Anilin- und Sodafabrik. J. Jahn, and V. Tafel observed that, unlike nickel oxide, cobalt oxide is reduced by water-gas at 250° to 350° . H. T. Kalmus said that producer gas is the cheapest reducing agent to employ for industrial purposes, and that the metallic product should be cooled in a reducing atmosphere. P. E. Martin, and D. Mendeléeff reduced the oxide by heating it in a current of hydrocarbons.

C Brunner reduced ammonium cobalt oxalate to metal by heating it in a closed crucible. H. Copaux observed that the product of the action of heat on cobalt oxalate is a mixture of cobalt, and cobalt oxide, and that the reduction should be completed by heating the product in hydrogen. W. Biltz said that a very reactive form of cobalt is obtained rapidly by heating to redness in hydrogen, at 120° ; the powdered and dried oxalate. The product is powdered and again heated in hydrogen. A. Brochet observed that the cobalt obtained from the oxalate is not pyrophoric. W. O. Snelling obtained the metal by heating the formate at a low temp. in vacuo, or in hydrogen. The metal is very reactive, but, according to A. Brochet, it is not pyrophoric. J. Riban observed that some metal, as well as oxide, is formed when a soln. of cobalt formate is heated at 175° in a sealed and evacuated vessel.

W. Müller, C. H. Wolff, A. Sieverts, G. Magnus, C. Zimmermann, J. Jahn, and W. Ohl observed that the oxide or oxalate is reduced by heating it in a current of hydrogen. W. Müller, F. Glaser, and G. Gallo thought that a suboxide is formed—*vide infra*. W. Müller said that the reduction of cobalt oxide by hydrogen begins at 320° ; H. Moissan, 190° to 200° , and that pyrophoric metal can be formed at 250° ; and F. Glaser observed that the reduction of the oxide occurs at 228° , and that the

weights obtained at 250°, 306°, and 298° are constant, owing to the intermediate formation of hydrides. T. W. Richards and G. P. Baxter observed that cobalt oxide is only slowly reduced by hydrogen at the temp. available in a hard glass tube. G. Gallo said that 'he reduction begins at 118°, and is completed in 4 hrs. at 400°, in 15 minutes at 700°. G. F. Hüttig and R. Kassler observed the yield obtained by heating hydrated cobaltic oxide in hydrogen for 5 hrs. at :

	250°	300°	350°	400°	500°
Cobalt.	77.52	84.25	91.82	99.34	99.86 per cent.

H. T. Kalmus obtained a 90 per cent. reduction in a few minutes between 500° and 700°, but the subsequent progress of the reaction was slow ; and as the temp. rises from 700° to 1100°, the proportion reduced in the first few minutes with rise of temp. rapidly increases to 100 per cent. Thus :

	609°				824°			1073°			
Time	7	15	30	60	2.5	30	150	1	5	30	60 mins.
Reduction	62.2	81.8	83.0	93.0	98.5	99.0	99.2	90.0	99.4	99.8	100 per cent.

when the product is cooled in hydrogen. The reduction of the oxide for industrial purposes was described by T. A. Edison, and H. C. Hubbell ; and for the preparation of a cobalt catalyst, by the Farbenindustrie Aktien Gesellschaft, I. L. Fohlin, C. Ellis ; and H. S. Taylor and R. M. Burns, E. Péligot, and W. Spring obtained crystals of cobalt by reducing the cobalt chloride in hydrogen ; and C. Winkler, and W. Spring obtained mirrors of cobalt by reducing the vapour of the chloride with hydrogen.

H. Rose obtained cobalt by heating a mixture of cobalt oxide and ammonium chloride. T. W. Richards and G. P. Baxter said that a spongy metal is produced when the oxide is reduced by heating it in a current of ammonia ; C. Winkler said that the metal appears as a black powder which glows in air. C. Winkler, and B. Kerl reduced cobalt chloride by heating it in ammonia. E. Péligot, E. H. von Baumhauer, R. Schneider, W. Sharwood, W. Casselmann, S. P. L. Sørensen, and F. Claudet obtained cobalt by heating the chloride or the aminochloride in hydrogen.

J. Jahn, and H. T. Kalmus reduced the oxide by aluminium in the thermite process. The thermal value of the reaction is : $3\text{Co}_3\text{O}_4 + 8\text{Al} = 4\text{Al}_2\text{O}_3 + 9\text{Co} + 9.902 \text{ Cals.}$ L. Weiss and O. Aichel used mischmetal instead of aluminium. H. Moissan obtained cobalt by the distillation of the amalgam.

H. St. C. Deville melted cobalt in a lime crucible standing inside a graphite crucible ; A. A. Valenciennes employed a magnesia crucible arranged in a similar way. C. Winkler melted the cobalt along with about 25 per cent. of cobalt oxide in a porcelain crucible. The Berndorfer Metallwaarenfabrik reduced the oxide to metal, moistened the metal with a 4 per cent. soln. of potassium permanganate, and melted the product in a suitable furnace. H. Copaux said that cobalt takes up silica from the so-called magnesia or alumina crucibles, and he recommended crucibles made of aluminium silicate bonded with calcium aluminate.

A. C. and E. Becquerel obtained a bright deposit of cobalt by the electrolysis of a soln. of cobalt chloride which had been neutralized with ammonia or potassium hydroxide. A. Gaiffe, H. T. Kalmus, L. Schlucht, H. Fresenius and F. Bergmann, and F. Mylius and O. Fromm used a similar process. C. Winkler recommended 100 c.c. of a soln. of cobalt sulphate having 11.62 grms. of cobalt per litre, 30 grms. of aq. ammonia of sp. gr. 0.905, and 500 c.c. of water. The electrodes consisted of two platinum plates, 9.4 cms. \times 5.9 cms. ; and the current employed was 0.7 amp. at 3 volts.

A. C. Becquerel observed that *copper* immersed in a soln. of sodium cobalt chloride, acquires a coating of cobalt. According to Z. Roussin, D. Vitali, A. Siemens, and A. Commaille, *magnesium* deposits cobalt from slightly acid soln. of

cobaltous salts. S. Kern obtained an incomplete precipitation as hydrated oxide ; and K. Seubert and A. Schmidt obtained a complete precipitation as cobaltous hydroxide. T. M. Careis, H. Grosse-Bohle, The Farbenindustrie Aktien Gesellschaft, A. E. Demarçay, Z. Roussin, and J. L. Davies reduced cobalt from soln. of cobalt salts by means of *zinc*. N. W. Fischer obtained no precipitation with soln. of cobalt nitrate. According to L. de Boisbaudran, cobalt is not precipitated from neutral soln. by zinc except in the presence of a metal easily reducible by zinc—*e.g.*, lead or copper, but not cadmium ; if a copper salt be present, copper alone is deposited if the liquid is acidic. F. Stolba, and C. Mène obtained analogous results with zinc, and L. de Boisbaudran, with *cadmium*. R. Kremann and co-workers observed that with a soln. of cobalt sulphate at ordinary temp., zinc or cadmium precipitates cobalt largely in a form of cobaltous hydroxide ; but less hydroxide is formed at 100°. The reaction is not only dependent on the temp. but also on the ratio, Co : Zn, or Co : Cd, and on the conc. of the soln. The cobalt forms a solid film or an alloy at the surface of the precipitant. M. Centnerszwer and J. Drucker studied the effect of the conc. of the soln. on the reaction. R. Müller and F. R. Thois observed an incomplete precipitation by zinc or cadmium with a soln. of cobaltous chloride in ethyl alcohol. A. Damour obtained cobalt amalgam by the action of zinc amalgam on a soln. of a cobalt salt. C. Formenti and M. Levi observed that *aluminium* precipitates cobalt as a black powder from soln. of the nitrate, acetate, or chloride. W. C. Reid found that *thallium* deposits a basic salt from a soln. of cobalt nitrate. O. Prelinger found *manganese* precipitates cobalt from soln. of cobalt salts ; and M. Perry, that *iron* precipitates cobalt first from a mixed soln. of salts of cobalt, iron, nickel, and manganese. L. Kritschewsky observed that *hydrogenized palladium* does not reduce a soln. of a cobalt salt to metal ; and B. Neumann, that hydrogen in the presence of palladium does not precipitate cobalt from a soln. of its simple or complex salts. W. Ipatéeff and B. Zragin found that under a press. of 100 atm. *hydrogen* precipitates a mixture of cobalt and cobalt sulphate from 2*N*-CoSO₄ and 0.2*N*-CoSO₄, but with 4 days' heating, the reaction is not completed ; at 100°, soln. of the nitrate give no metal ; but with chloride soln., there is a small yield of metal. J. H. Weibel said that the separation of cobalt and cobalt oxide by hydrogen or carbon monoxide begins at 250° ; but at 300°, only cobalt is formed. The subject was further examined by the Farbenindustrie Aktien Gesellschaft, and W. D. Richardson. T. W. Richards and G. P. Baxter² found that an ammoniacal nitrate soln. furnishes an oxy-salt which makes the electrolysis impossible ; but an ammoniacal soln. of the sulphate furnishes a good deposit with a current density of 0.7 amp. per sq. dm. E. Vogel obtained spongy deposits with 0.5*N*-CoSO₄ and 0.1*N*-CoSO₄ and 8.5 amps. per sq. dm. According to H. G. Denham and S. W. Penny-cuick, reproducible cobalt electrodes are formed by deposition on platinum from a soln. of cobalt chloride containing 2 c.c. of a 5 per cent. soln. of phosphoric acid, 20 c.c. of a 10 per cent. soln. of sodium dihydrophosphate, and 2 c.c. of a sat. soln. of sodium dihydrophosphite and a current density of 0.008 amp. per sq. dm. during 24 hrs.

B. Neumann observed that the deposits obtained from a soln. of cobalt chloride or sulphate and boric acid are hard, bright, and white, but readily peel off if too thick. G. B. Bomino and M. Bottini obtained *cobaltized cobalt*—analogous to platinized platinum—on platinum from a soln. of cobalt and ammonium sulphates, using 4.5 volts for half an hour, and then 50 to 60 volts for 1 minute. E. Müller and P. Spitzer obtained a deposit of spongy cobalt on platinum with a very high current density, and an acidified soln. of cobalt sulphate. A. Estelle produced cobalt as a fine powder by the electrolysis of a neutral soln. of a cobalt salt mixed with an organic hydroxyl-compound like sugar or glycerol. According to V. Kohlschütter and F. Jakober, the contraction developed by the deposition of a film of cobalt on platinum depends on the current density, temp., and composition of the electrolyte.

F. Mylius and O. Fromm found that with a cobalt cathode on the bottom of

a sat. soln. of cobalt sulphate, and a platinum wire anode, flecks of cobalt appear on the surface of the soln.

R. Schildbach observed that the occluded hydrogen is greater at low temp., and is very small at higher temp., and this hydrogen causes a fall of potential after the current is broken. With a neutral soln. of cobalt sulphate at 0°, 20°, 50°, and 92°, the fall of potential was, respectively, 45, 18, 9, and 4 millivolts. Observations were made by F. Förster, H. T. Kalmus, M. M. Raessler, O. P. Watts, C. Winkler, and R. Schildbach discussed the presence of oxide in electro-deposited cobalt. A. C. and E. Becquerel, and M. M. Raessler noted the contamination of the deposit with iron.

According to G. Coffetti and F. Förster, some hydrogen is evolved in the electrolysis of soln. of cobalt sulphate, and R. Schildbach observed that from neutral soln. in an atm. of hydrogen, cobalt is deposited with quantitative current efficiency. The difference of potential between the electrode and the electrolyte is, however, much larger than the equilibrium value. The difference increases with the current density, and diminishes as the temperature rises, almost vanishing at 90°; it is very much increased by the addition of small quantities of acid to the solutions, and this effect is especially marked at low temp. M. J. Udy observed that in the electrolysis of soln. of cobalt sulphate, containing 0.3 to 1.0 per cent. of free sulphuric acid, the current efficiency is 80 to 95 per cent.; and with 5 per cent. of acid, about 8 per cent. The voltage required for soln. with up to 1 per cent. of free acid is 0.5 to 2.0 volts lower than it is with neutral soln. having the same current efficiency—there is a strong tendency for oxides to be formed on the anode. J. H. Paterson showed that with dil. soln., and low current densities there is a cathodic separation of hydroxide and hydrogen. M. M. Raessler's observations on the influence of composition, acidity, temp., and current density, D , amp. per sq. dm., at the cathode, on the deposition of cobalt are summarized in Table I.

TABLE I.—THE EFFECT OF VARIABLES ON THE DEPOSITION OF COBALT.

2.500	2.60	63.73	1.55	80.55	1.32	82.24

The preparation of cobalt by electrolysis has not developed very far industrially. The subject was discussed by H. T. S. Britton, J. L. G. de Burlet, E. B. Cutten, N. H. M. Dekker, V. Engelhardt, C. Hoepfner, V. N. Hybinette, G. H. Montillon and N. S. Cassel, C. J. Reed, and M. J. Udy. C. J. Reed obtained an amalgam by

electrolysis with a mercury cathode, and removed the mercury by distillation. H. Moissan also obtained cobalt by distilling mercury from the amalgam. J. W. Beckmann electrolyzed a fused mixture of cobalt oxide and lime; and H. Skappel electrolyzed fused sulphide, or a mixture of sulphide and oxide.

H. Roehler electrolyzed soln. of cobalt chloride in formamide, but did not obtain deposits of the metal; but H. A. Pagel and O. C. Ames, and L. F. Yntema and L. F. Audrieth obtained a deposit with a soln. of cobalt acetate in formamide at 100°; and with a soln. of cobalt chloride in acetamide at 100°, but not with soln. of cobalt chloropentamminochloride or of potassium cobaltcyanide in acetamide at 100°. H. S. Booth and M. Merlub-Sobel studied the deposition of cobalt from soln. of thiocyanate in liquid ammonia.

The deposition of cobalt for electrochemical analysis has been investigated by many. A. Classen recommended using a soln. of 0.3 grm. of cobalt sulphate, 4 to 5 grms. of ammonium oxalate made up to 120 c.c., and employing a current density of 1 ampere per sq. dcm. for 2.5 to 3.5 hrs. at 60° to 70°, and 3.1 to 3.8 volts. According to F. M. Perkin, the deposit is contaminated with a little carbon. H. Fresenius and F. Bergmann recommended as an electrolyte: 0.5 grm. of cobalt sulphate, 5 to 6 grms. of ammonium sulphate, and 40 c.c. aq. ammonia of sp. gr. 0.96 made up to 150 to 170 c.c., using 0.7 amp. at 20° to 25°; B. Neumann recommended: 1 grm. of cobalt chloride, 5 grms. of ammonium chloride, and 30 c.c. aq. ammonia made up to 150 c.c., using 1.5 amp. for 5 to 6 hrs.; E. F. Smith added 0.1 grm. more potassium cyanide to a soln. of a cobalt salt than is needed for precipitation and re-solution, along with 2 grms. of ammonium carbonate made up to 150 c.c., and using 1.5 amp. at 60° and 6.0 to 6.5 volts for 3.5 hrs. B. Neumann added that if the potassium cyanide is in excess, the separation of cobalt is incomplete. F. M. Perkin and co-workers recommended adding to a soln. of the cobalt salt, 2 c.c. of a 5 per cent. soln. of phosphoric acid, and 20 to 25 c.c. of a 10 per cent. soln. of sodium dihydrophosphate. The subject was studied by J. M. Albahary, D. Balachowsky, A. Brand, O. Brunck, E. D. Campbell and W. H. Andrews, M. S. Cheney and E. H. S. Richards, A. Classen and M. A. von Reis, O. Ducru, N. V. Emelianova, M. Engels, A. Fischer and co-workers, F. Förster, H. Fresenius and F. Bergmann, O. W. Gibbs, R. von Foregger-Greifenturn, V. Kohlschütter and F. Jakober, C. A. Kohn and J. Woodgate, C. Lucknow, Mansfeldsche Berg- und Hüttendirektion in Eisleben, E. Murmann, B. Neumann, H. Nissenson and H. Danneel, F. Oettel, W. Ohl, H. A. J. Pieters, O. Piloty, N. A. Puschin and R. M. Trechzinsky, A. Rosenheim and E. Huldskinsky, A. Riche, J. E. Root, G. A. le Roy, F. Rüdorff, L. Schlucht, C. P. Schweder, M. Schlötter, H. Thomälen, G. Vortmann, A. Waller, H. S. Warwick, and F. Wrightson. E. F. Smith and co-workers obtained good results with soln. containing formic acid, lactic acid, or a lactate. P. Bruylants, F. F. Exner, H. Fresenius and F. Bergmann, E. F. Smith and co-workers, B. Tougarnoff, and K. Wagemann used a rotating anode, with or without a mercury cathode, for the rapid precipitation of cobalt from soln. of the chloride or sulphate.

In 1842, R. Böttger³ showed that metal could be coated with cobalt electrolytically. The similarities between cobalt and nickel are so great that much of the work which has been done on the electroplating of nickel can be applied to the electroplating of cobalt. This is the conclusion from the various writers—G. Langbein, A. Hollard and L. Bertiaux, A. Brochet, W. Pfanhäuser, W. G. McMillan and W. R. Cooper, A. Watt, S. P. Thompson, E. Brüant, W. Maigne and O. Mathey, and W. R. Barclay and C. H. Hainsworth. Several of the earlier soln. which were proposed, were based on that of A. C. and E. Becquerel indicated above. Thus, G. W. Beardslee used a soln. of 30 to 45 grms. of cobalt chloride per litre of water made faintly alkaline with ammonia; I. Adams, 22.5 grms. of cobalt chloride and 15 grms. of ammonium or magnesium chloride. E. D. Nagel employed a soln. of 400 parts of cobalt sulphate, and 200 parts of ammonium sulphate, dissolved in 6000 parts of distilled water mixed with 120 parts aq. ammonia of sp. gr. 0.909.

The soln. was employed at 38°. I. Adams also employed soln. of cobalt sulphate with ammonium or magnesium sulphate. A. Brochet also used a soln. of ammonium cobalt sulphate; and S. P. Thompson, either a soln. of 60 grms. of cobalt sulphate, 30 grms. of magnesium sulphate, and 60 grms. or less of ammonium sulphate; or a soln. of 100 grms. of ammonium cobalt sulphate, 50 grms. of magnesium sulphate, 6.2 grms. of citric acid, and 12.5 grms. of ammonium carbonate. W. Maigne and O. Mathey used a soln. of 28.6 grms. cobalt chloride, 14.3 grms. of potassium cyanide, and 143 grms. of sodium thiosulphate; or else a soln. of 20 grms. of cobalt chloride and 10 grms. of potassium thiocyanate. G. Langbein, and B. Neumann used a soln. of 40 grms. of ammonium cobalt sulphate and 20 grms. of boric acid. J. Vanderersch used a soln. of cobalt along with one of several acids—benzoic, salicylic, boric, gallic, pyrogallic, sulphurous, perchloric, formic, lactic, or acetic acid. M. Kugel recommended the addition of 1 to 10 grms. per litre of perchloric, perbromic or sulphuric acid at 30°. A. Classen used a hot soln. of 50 grms. cobalt sulphate, 80 grms. of ammonium oxalate, 20 grms. of potassium oxalate, and a litre of water. E. Placet and J. Bonnet specified the use of “bisulphate, biphosphates, and biacetates.” H. T. Kalmus and co-workers recommended 200 grms. of ammonium cobalt sulphate per litre for current densities up to 4 amps. per sq. dcm.; and 312 grms. cobalt sulphate, and 19.6 grms. sodium chloride per litre, and nearly saturating the soln. with boric acid for current densities between 3.5 and 26.4 amps. per sq. dcm. G. Fuseya and co-workers studied the effect of various additions to the bath.

A. Watt tried soln. of various kinds, and H. T. Kalmus and co-workers studied the subject. It was concluded that by the methods just indicated, cobalt can be deposited on to brass, iron, steel, copper, tin, lead, Britannia metal, and German silver, so as to give a firm adherent, hard, uniform surface which can be buffed and finished to give a white metal with a bluish cast, and possessing good lustre. The deposit of cobalt is harder than that of nickel, and it can be hammered, bent, or burnished as in the tests applied to nickel deposits. The electrical conductivity of the cobalt soln. is greater than is the case with ordinary nickel soln., and they can therefore be worked at a lower voltage for a given speed of plating.

Electroplating with cobalt was discussed by W. S. Barrows, A. C. and E. Becquerel, C. H. Buchanan and T. Haddom, B. Carr, Farbenindustrie Aktien Gesellschaft, M. Fiedler, C. Formenti and M. Levi, A. Gaiffe, T. H. Gant, B. Jirotko, P. R. Jourdain and A. R. Bernard, W. G. Knox, D. J. McNaughton and A. W. Hotherhall, P. Marino, Q. Marino, C. P. Madsen, G. H. Montillon and N. S. Cassel, E. D. Nagel, A. Nefgen, A. Rosenberg, G. A. Roush, M. Schlötter, L. Schulte, O. Sprenger, F. T. Taylor, H. N. Warren, and E. Weintraub.

W. Guertler and G. Tammann⁴ observed that the cobalt of commerce contained 2.22 per cent. nickel, 0.08 per cent. copper, 0.23 per cent. iron, and 0.04 to 0.06 per cent. of matter insoluble in acid, whilst the *cobaltum purissimum* of commerce had 1.62 per cent. nickel, 0.10 per cent. iron, and traces of copper. H. Copaux said that the cobalt of commerce contains sulphur, phosphorus, copper, aluminium, calcium, iron, and nickel; and in addition, S. P. L. Sørensen found lead, arsenic, zinc, manganese, alkaline earths, and silica. H. T. Kalmus found that cobalt reduced from commercial oxide contained 96.8 to 99.63 per cent. of cobalt; 0 to 0.65 per cent. of nickel; 0.56 to 2.36 per cent. of iron; 0.021 to 0.47 per cent. of sulphur; 0.062 to 0.24 per cent. of carbon; 0 to 0.06 per cent. of calcium; 0 to 0.14 per cent. of silica; and about 0.06 per cent. of manganese, 0.11 per cent. of arsenic; and 0.017 per cent. of phosphorus. H. Moissan's cobalt prepared in the electric furnace contained 0.733 per cent. of impurity. The subject was discussed by P. Georgi and G. Schnieder, C. Winkler, and W. Hessenbruch. A. Sieverts and W. Krumbhaar removed occluded gases by heating the metal to 1400°. B. Egeberg removed zinc by volatilization from the molten metal; C. Winkler, carbon, by heating the metal with cobalt oxide; B. Bogitch, sulphur,

by heating the metal with wood-charcoal; and P. Manhès, iron and sulphur, by fusion with alkali fluxes.

The melting and casting of cobalt were discussed by H. Copaux,⁵ W. Hankel, C. Winkler, and S. B. Wright, for containing vessels—*vide supra*. The mechanical working of the metal was discussed by Berndorfer Metallwaarenfabrik, C. Brunner W. B. Clarke, H. Copaux, P. G. Ehrhardt, T. Fleitmann, P. Georgi and G. Schnieder, H. T. Kalmus, P. McCorkle, E. Maurer, P. F. Monnot, G. Selve and F. Lotter, A. Valenciennes, and C. Winkler. T. Fleitmann prepared **malleable cobalt** by adding magnesium to the molten metal as described for nickel (*q.v.*). S. Kaya obtained **single crystals of cobalt** several c.c. in vol. from 99.8 per cent. electrolytic cobalt, by cooling molten cobalt extremely slowly when the metal is in the vicinity of its transition temp. Many processes of reduction of cobalt salts in aq. soln., the reduction of the oxide by hydrogen, and distillation of the amalgam, and the thermal decomposition of the carbonyl, furnish **pulverulent cobalt**. A. Estelle also obtained a fine powder by the electrolysis of a neutral salt of cobalt mixed with a hydroxylic organic compound—sugar or glycerol. G. Magnus prepared **pyrophoric cobalt** by reducing the oxides in a current of hydrogen. H. Moissan added that the best temp. for reduction is about 250°; if the metal is reduced at 700°, or obtained by distilling the amalgam, it is not pyrophoric. N. Nikitin also found that the oxalate reduced between 275° and 350° is not pyrophoric, but if the oxalate is previously triturated alone or mixed with less than 50 per cent. of manganous oxalate and heated to 330° to 350°, it furnishes pyrophoric cobalt. C. Winkler, and B. Kerl said that when cobalt oxide is reduced with ammonia so that it contains 14 to 16 per cent. of oxygen, it glows when exposed to air. Pyrophoric cobalt is a black powder which burns brilliantly when exposed to air in consequence of rapid oxidation.

A. Kundt, H. Bracchetti, L. R. Ingersoll, J. Strong and C. H. Cartwright, W. Lobach, A. Skinner and A. G. Tool, E. Breuning and O. Schneider, R. M. Bozorth, E. Hirsch, V. Kohlschütter and F. Jakober, and E. P. T. Tyndall and W. W. Wertzbaucher discussed the preparation of **cobalt mirrors** electrolytically—*vide* iron mirrors; A. Skinner and A. G. Tool, E. O. Hulburt, and J. D. Hanawalt and L. R. Ingersoll, by cathodic spluttering; A. Knocke, J. C. Steinberg, and A. J. Sorensen, by the evaporation of cobalt, which begins in vacuo at about 640°; W. Spring, by the reduction of the vapour of cobalt chloride with hydrogen; and F. K. Richtmyer and F. W. Warburton, by reducing the oxide, composed to a thin layer, with hydrogen. T. A. Edison, and H. C. Hubbell prepared films of oxidation and reduction, and treated them with dil. acids to remove iron, and arsenic; the resulting surfaces were said to be very active chemically. G. F. Taylor obtained **cobalt filaments** by drawing the molten metal enclosed in a suitable quartz-glass tube, and afterwards removing the glass with hydrofluoric acid.

F. Ehrenhaft,⁶ and O. Scarpa prepared **colloidal cobalt** by electrical spluttering under water by G. Bredig's method—3. 23, 10—and T. Svedberg added that the product was probably a colloidal hydroxide or oxide. T. Svedberg prepared the colloid by an oscillating discharge—3. 23, 10. C. Benedicks, D. Zavrieff, A. H. Erdenbrecher, and J. Billitzer also prepared the colloid by electrical spluttering. The Chemische Fabrik von Heyden obtained the colloid by electrical spluttering in the presence of a reducing agent, and a protective colloid, and found that with 0.03 per cent. of cobalt, the sol is very dark brown, almost black in reflected light, and dark brown in transmitted light. A. Pieroni and E. Girardi reduced pyridine soln. of cobalt salts by a soln. of pyrogallol, pyridine, and diluted the mixture with water—if cobalt acetate is used, the dilution with water is not necessary. C. Paal, and C. Paal and H. Boeters obtained the hydrosol by reducing a hydrosol of cobalt hydroxide in the presence of a hydrosol of palladium—with sodium protalbate or lysalbate as protective colloid. H. H. Franke used gum arabic, gelatin, gum tragacanth, saponin, and sodium lysalbate as protective colloid, and hydrazine, or a salt of hydrazine, in the presence of alkali, as reducing

agent. The hydrosol or hydrogel is reversible. L. Hugounenq and J. Loiseleur used glycogen as protective colloid. A. Job and R. Reich obtained a colloid by the action of ethylmagnesium bromide on cobalt iodide in benzene. H. Nordenson said that colloidal cobalt is not formed by the action of ultra-violet light, or X-rays, or radium rays on cobalt in contact with water or other dispersion media. The oxidizable metals yield hydrated oxides, and the action of these radiations is to accelerate changes which occur in their absence. T. Svedberg prepared **alcosols** by oscillatory sparking under isobutyl or ethyl alcohol as dispersive medium. A. Lesure obtained a colloidal suspension in oil for intramuscular injections.

§ 6. The Physical Properties of Cobalt

The cobalt obtained by the reduction of the oxide in hydrogen, is a grey or black powder. A. A. Valenciennes¹ said that the metal *en masse*, after it has been fused, has the **colour** of polished iron; whilst H. T. Kalmus and co-workers said that its colour is like that of nickel, although, when plated and polished, it is silver-white with a slight bluish tinge. C. Brunner, W. A. Lampadius, P. Georgi and G. Schneider, H. Nagaoka and K. Honda, and H. Copaux also said that the metal is silver-white, and C. Winkler, that it is bluish-white or greyish-white like zinc. Sometimes cobalt appears as a black matte. According to A. W. Wright, a thin film of cobalt in transmitted light appears grey or brownish-grey; and G. T. Beilby said blue. P. Berthier said that the metal has a fracture like that of cast-iron. E. van Aubel discussed the colour and transparency of thin films of cobalt.

H. T. Kalmus and co-workers,² R. Vogel, R. Ruer and K. Kaneko, and K. Friedrich observed that deep etching shows massive cobalt to contain polyhedral **crystals**. R. Ruer and K. Kaneko observed twinning in the crystals of cast cobalt, and R. Vogel added that twinning is an effect of cold-work, and vanishes when re-crystallization occurs during annealing. R. Vogel observed Neumann's lines; G. Tammann and Q. A. Mansuri, the re-crystallization of cobalt; F. Sauerwald, the grain-growth during sintering; G. Quincke, the formation of what he called foam-cells during the solidification of the molten metal; and R. M. Bozorth, and R. Vogel, the orientation of the crystals. Cobalt is dimorphous in that it forms a variety with hexagonal crystals stable at ordinary temp., and a variety with cubic crystals stable above 400°, although both forms may be present in ordinary cobalt. S. B. Hendricks and co-workers said that cobalt has a hexagonal lattice above 1015° and below 400°, and in between, a cubic lattice. H. Perlitz studied the

distance apart of the atoms. G. T. Beilby observed that the polished metal has a transparent, glass-like film which may pass into minute scales or granules. H. Kersten, R. M. Bozorth, F. Bitter, and V. Kohlschütter and F. Jakober studied the structure of the electro-deposited metal.

A. W. Hull observed that the **X-radiograms** of electro-deposited cobalt correspond with a close-packed, hexagonal lattice—Fig. 2—with the side of the

FIG. 2.—Close-packed, Hexagonal Lattice of Cobalt.

elementary, triangular prism $c=2.514$ A., and the distance between the nearest atoms, $a=2.514$ A., or $a:c=1:1.633$; S. Sekito gave $a=2.498$ A., $c=4.052$ A., and $a:c=1:1.622$; A. Osawa gave $a=2.492$ A., $c=4.056$ A., and $a:c=1:1.63$; and F. Wever and U. Haschimoto, $a=2.514$ A., $c=4.17$ A., and $a:c=1:1.66$. A. W. Hull observed that filings of the metal, after being heated in hydrogen to 600° for 6 hrs., possessed a mixture of cubic and hexagonal lattices in about equal proportions. It was not possible by annealing to complete the transformation from the hexagonal to the cubic form, but by reducing the oxide in hydrogen at 600° , the metal had a face-centred, cubic lattice of side $a=3.554$ A., and a distance of 2.514 A. between the nearest atoms. S. Sekito found for the cubic lattice $a=3.558$ A.; F. Wever and U. Haschimoto, $a=3.554$ A.; A. Osawa, $a=3.525$ A.; and L. Vegard and H. Dale, $a=3.533$ A. H. Kahler, E. A. Owen and E. L. Yates, A. Karlsson, H. Shoji, S. B. Hendricks and co-workers, H. Masumoto, R. W. G. Wyckoff, and E. C. Bain discussed this subject. L. R. Ingersoll and J. D. Hanawalt found that a cobalt film spluttered in nitrogen is metallic and non-magnetic; it has a face-centred, cubic lattice, with $a=4.297$ A., and this reduces to the normal, face-centred, cubic lattice with $a=3.554$ A., when it is degassed and crystallized at 400° ; and H. Kahler observed that a film obtained by cathodic spluttering had a regular orientation of crystallites of both cubic and hexagonal forms. G. Sachs studied the effect of mechanical work on the lattice; and W. H. Rothery, the relations amongst the lattice constants of cobalt and other metals.

From a study of the gold-cobalt alloys, W. Wahl³ inferred that above 1400° , cobalt forms cubic crystals, and below that temp., hexagonal crystals. H. Pechaux also considered that two breaks in the thermoelectric curve of cobalt at 280° and 550° represent **allotropic transformations**. K. Konda and S. Shimizu observed discontinuities in the effect of temp., on the magnetization of cobalt, and inferred that there is a transition temp., or change of phase at 464° . It is now known that cobalt exists at ordinary temp. in a form, **α -cobalt**, with a stable, close-packed, hexagonal lattice, and that at the **transition temperature**, about 400° , it furnishes **β -cobalt**, the stable form above 400° , and possessing a face-centred, cubic lattice. Both forms may exist side by side at ordinary temp., but α -cobalt is the stable form, β -cobalt the unstable form. U. Dehlinger and co-workers discussed the mechanism of the transformation and inferred that a single crystal suffering an allotropic transformation does so by a simple shearing movement of the atoms on that atom plane of the proper family of planes which will produce the smallest increase in the surface area of the crystal.

A. Schulze observed that the temp. coeff. of the electrical resistance of cobalt of a high degree of purity remains nearly constant between 444° and 467° ; and that the reverse transformation is completed at about 350° ; with cobalt containing 0.47 per cent. of iron, the transformation temp. is between 403° and 446° , and the reverse transformation is completed at 150° . Measurements of the thermal expansion indicate a transformation between 451° and 452° , and the reverse transformation ends at about 100° . Measurements of the thermoelectric force against platinum indicate a transformation between 456° and 470° . A. Schulze gave 444° for the transition temp.; S. B. Hendricks and co-workers gave 400° ; G. Wassermann, 450° ; S. Umino, 460° ; and P. H. Emmett and J. F. Schultz between

340° and 360°—but this last result is too low. H. Masumoto observed that the effect of impurities on the transformation temp. is irregular when determined by observations on the thermal expansion, thermal effects, electrical resistance, or magnetization. Both forms are ferromagnetic, and the transformation exhibits an hysteresis being much lower on a falling temp. than it is on a rising temp. With cobalt of the highest degree of purity, and with the following percentage proportions of iron—other impurities in brackets—the observed transformation temp. were :

Impurities	.	.	0	0.04 (0.189)	0.10 (0.162)	0.33 (0.086) per cent.
Transition	{ Heating	.	477°	447°	442°	427°
	{ Cooling	.	403°	400°	400°	360°

S. B. Hendricks and co-workers observed that β -cobalt appears when cobaltous oxide is reduced in hydrogen above 400°, and after standing 7 months, it shows no sign of the presence of α -cobalt; but the cast metal, and cobalt reduced from cobaltous oxide by hydrogen above 1015° has the close-packed hexagonal lattice of α -cobalt. The cubic form is therefore stable between 400° and 1015°. According to A. W. Hull, a sample of 99.7 per cent. cobalt gave an X-radiogram consisting only of α -cobalt; and after heating for about 6 hrs. at 600° in hydrogen, it contained about equal proportions of α - and β -cobalt; it was not possible to obtain a complete transformation into β -cobalt at this temp. Cobalt obtained from the oxide reduced by hydrogen at 600° consists of β -cobalt, and only traces of α -cobalt. The electrolytic metal contains about equal parts of the two forms, whereas S. Sekito found that the electrolytic metal often contains only α -cobalt. S. Kaya found that a slowly-cooled sample, with 0.116 per cent. of iron, and 0.0924 per cent. of other impurities, consisted entirely of α -cobalt; and A. B. Cardwell observed commercial samples of 99.9 per cent. cobalt sometimes contained β -cobalt, and other samples not so. M. R. Andrews observed that alloys with 100 to 5 per cent. of iron had the cubic lattice; alloys with 2 per cent. of iron had the cubic lattice and faint signs of the hexagonal lattice, and cobalt alone had the hexagonal lattice. A. Rogers found that electrolytic cobalt previously heated to 500°, had a transition temp. of 420° and when melted in vacuo, and heated to 1100°, the transition temp. was 445°. F. Wever and U. Haschimoto attributed the variations in the determinations of the transition temp. as due to strong hysteresis, and to the presence of different proportions of the two allotropes in the metal prepared in different ways. C. L. Utterback observed an irregularity in the total reaction of cobalt between 1047° and 1107° corresponding with the Curie point.

The transformation was shown by H. Masumoto, W. C. Ellis, and S. B. Hendricks and co-workers to be influenced by strong magnetic fields. According to A. B. Cardwell, in the intermediate stages of the transformation the photoelectric and thermionic sensibilities are augmented; and he believes that the purified metal, thoroughly free from occluded gases, will have a higher transition temp. than that usually accepted. For the energy changes during the transformation, *vide infra*.

Both α - and β -cobalt are ferromagnetic, and H. Masumoto found that cobalt becomes paramagnetic at 1100°. This, the Curie temperature, corresponds with the A_2 -arrest of iron at 790°, and with nickel, at 380°. S. Umino gave 1150° for the Curie temp., and A. Schulze, 1128°—*vide infra*. There is a doubt whether the temp. of magnetic transformation is connected with a change of phase. G. Wassermann observed no allotropic transformation point at 10° to 15°. W. Guertler and G. Tammann, and R. Ruer and K. Kaneko considered that there is also a polymorphous change at the Curie temp. H. Masumoto, however, said that there is no change of phase, or of atomic arrangements. S. N. Hendricks and co-workers also said that there is no change in the lattice constant at the Curie temp., 1103°, although there is a transformation temp. at 1015°—*vide supra*. A. Schulze said that the curves of electrical resistance, and thermoelectric force against platinum change their direction at 1128°, but there is no abrupt change as usually occurs with changes of phase.

T. Bergman⁴ gave 7.7 for the **specific gravity**, but his metal was impure, and the datum was too low; J. J. Berzelius gave 8.5131; C. Brunner, 8.485; B. M. Tassaert, 8.5385; S. Bottone, 8.5 at 15.5°; R. J. Häuy, 8.5384; W. A. Lampadius, 8.7; T. H. Henry, 8.558; and L. Playfair and J. P. Joule, 7.718 to 8.260; C. F. Rammelsberg gave for the reduced metal, 8.132 to 9.495—mean, 8.57. These observations, and those by F. A. C. Gren, were made before chemists had learned to purify the metal adequately. For the metal which had been fused, W. A. Tilden gave 8.718 at 21°/4°; G. Neumann and F. Streintz, and R. von Dalwitz-Wegner, 8.6; O. Block, 8.920; H. Copaux, 8.8 at 15°/4°; A. Schulze, 8.79 at 20°; and C. Winkler, for electrolytic cobalt foil, 7.9678 at 20°. T. M. Lowry and R. G. Parker gave 8.7706 for the metal in bulk, and 8.7453 for the cold-worked metal (filings). H. T. Kalmus and C. H. Harper found for 99.9 per cent. metal, cast from just above its m.p., about 1500°, 8.7562 at 15°; for the metal cast and swaged down to a thin cylindrical bar, 8.9227, at 19°; and for the cast metal, annealed at 700°, 8.8105 at 19°. A. W. Hull calculated for both the hexagonal forms a sp. gr. of 8.66, when the best representative value for ordinary cobalt is 8.8; S. Sekito similarly calculated 8.89 for α -cobalt and 8.64 for β -cobalt. J. A. Groshans discussed some relations of the density of cobalt. For cobalt reduced from the oxalate by hydrogen, W. Biltz and W. Holverschheit observed 8.83 at 25°/4°, and for the **atomic volume**, 6.68. I. I. Saslawsky, and E. Moles studied the at. vol.; and W. Biltz and K. Meisel calculated 6.58 for the at. vol. at absolute zero. The subject was studied by I. I. Saslawsky, and A. Heydweiller. E. Donath and J. Mayrhofer, I. Traube, and P. Niggli made observations on some relations of the at. vol. T. Barth and G. Lunde calculated from the lattice dimensions of the cubic form of cobalt the at. vol. 6.84, a value which lies between that of the cubic, face-centred forms of iron (7.11) and of nickel (6.53). F. Ephraim's relation between the dissociation temp., T° at 500 mm., and the at. vol. v , namely $T^{1/3}v^{1/3}=14.0$, furnishes 6.8. A. W. Hull, W. P. Davey, and J. K. Morse gave 1.257 Å. for the **atomic radius**; W. F. de Jong and H. W. F. Willems, 1.27 Å. to 1.29 Å.; and V. M. Goldschmidt, 1.26 Å. W. L. Bragg gave 1.37 Å. for the **ionic radius**. A. M. Berkenheim, M. L. Huggins, H. Grimm, E. Piwowarksy, P. Röntgen and W. Koch, E. Herlinger, E. J. Cuy, V. M. Goldschmidt, L. Pauling, P. Walden, R. G. Lunn, A. Ferrari and F. Giorgi, E. H. Westling, J. C. Slater, and E. T. Wherry made observations on this subject from which it follows that for trivalent cobalt, the effective at. radius is 0.29 to 0.47 Å.; for bivalent cobalt, 0.72 to 0.82 Å.; and for neutral cobalt atoms, 1.26 to 1.39 Å. G. Natta and L. Passerini found that if the radius of oxygen is 1.32 Å., that of cobalt is 0.80 Å.; and G. Natta and A. Reina gave 2.92 Å. for the diameter of the Co^{++} -ion. The subject was also discussed by V. M. Goldschmidt, G. Berg, A. F. Scott, H. Grimm, and O. E. Frivold. M. Toepler found that on melting, a gram of cobalt expands 0.0064 c.c. or 5.2 per cent. K. Honda and co-workers gave 2.03 per cent. for the expansion during the solidification of cobalt with 2.2 per cent. of carbon. A. Kapustinsky discussed the effect of solvation on the ionic radius.

J. B. Dumas observed that cobalt is scratched by glass of hardness 5.6 on Mohs' scale. S. Bottone gave for the **hardness** of cobalt 0.145, when that of nickel is 0.141, that of silver, 0.099, and that of the diamond, 0.300. S. F. Scherutshuschny and S. W. Belynsky gave 4, and H. Copaux gave 5.5 on Mohs' scale. T. Turner, and E. van Aubel said that cobalt is harder than iron. T. Turner found that the hardness of cobalt is 1450 when that of nickel is 1410; that of iron, 1375; and that of the diamond is 3010. M. Waehlert gave 136 for Brinell's hardness; and C. A. Edwards, 86.0. R. Ruer and K. Kaneko estimated that Brinell's hardness of cobalt is 132; and H. T. Kalmus and C. H. Harper found that the hardness of 99.9 per cent. cobalt, cast from just above its m.p. with a load 3400 lbs., is 124; the values for cast and sheet nickel are 83.1 and 85.1 respectively. Hence the hardness of cobalt cast from just above its m.p. is higher than that of iron or nickel cast under similar conditions. If commercial cobalt has 0.060 to 0.37 per cent. of carbon, the

increased hardness is not sufficient to affect variations due to heat-treatment. D. J. McNaughton, and D. J. McNaughton and A. W. Hothersall found that the Brinell's hardness of electro-deposited cobalt varies from 270 to 311; and L. Guillet and J. Cournot found that by immersion in liquid air, the hardness rose from 174 to 222 on Brinell's scale. E. Maurer said that by cold-working, involving a 3 per cent. extension, the hardness of cobalt with 4.15 per cent. of nickel rose from 180 to 280. M. Guichard and co-workers said that the hardness is independent of the hydrogen content.

The early observers—*e.g.*, P. Berthier, E. S. Clarke, and C. Brunner—noted that cobalt is malleable under the hammer. H. T. Kalmus and C. H. Harper observed that purified cobalt can be readily machined in a lathe, although it is somewhat brittle, and yields a short clip. The addition of a small proportion of carbon renders the metal less brittle, for it then yields a longer curling clip when turned. Purified cobalt cast in iron or sand moulds, slowly or rapidly cooled, cannot be directly swaged down to fine wire without special heat-treatment; but commercial cobalt, containing small percentages of carbon, can be readily swaged down from cast bars to wires of any desired diameter.

Observations on the **tensile strength** of cobalt were reported by H. St. C. Deville. The value for purified cobalt, cast and unannealed, is nearly 34,400 lbs. per sq. in. T. H. Gant gave 15.35 tons per sq. in. If the metal be annealed, the tensile strength is only slightly increased, the average value is 36,980 lbs. per sq. in. H. Copaux found the tensile strengths of iron, nickel, and cobalt to be respectively 23,000, 18,000, and 60,000 lbs. per sq. in. R. Ruer and K. Kaneko gave 25 kgrms. per sq. mm. for the tensile strength of cobalt. P. W. Bridgman gave 39.7 kgrms. per sq. mm. for the breaking stress of a wire of 0.0762 mm. diameter and annealed at a red-heat. H. T. Kalmus and co-workers observed that the percentage reduction in area, and the elongation are small for purified cast cobalt. The tensile yield-point is generally very close to the tensile breaking load. The tensile strength of cobalt increases rapidly as the metal is rolled, and it may attain 100,000 lbs. per sq. in. by being swaged down to wire. The effect of carbon is to raise the tensile strength from 34,400 lbs. per sq. in. for cast and unannealed metal to 61,000 lbs. per sq. in. for cobalt with 0.060 to 0.30 per cent. of carbon. The average value for 0.062 per cent. of carbon is 59,700 lbs. per sq. in., and for 0.25 per cent. of carbon, 61,900 lbs. per sq. in. The effect of carbon and other impurities in commercial cobalt is greatly to increase the percentage elongation and reduction of area, which rise in most cases well over 12 per cent.

H. T. Kalmus and C. H. Harper found that the **compressive strength** of purified cobalt, cast and unannealed, is about 122,000 lbs. per sq. in. The effect of annealing is not very marked, being near 117,200 lbs. per sq. in., so that annealing has a tendency to lower the compressive strength. The compressive yield-point of annealed and purified cobalt is 56,100 lbs. per sq. in. compared with 42,200 lbs. per sq. in. for unannealed cobalt, so that the yield-point is slightly raised by annealing. The compressive strength of purified cobalt cast just above its m.p., cooled in an iron mould, and machined in a lathe to test-bar size, is much greater than the corresponding values for iron and nickel. The effect of the presence of carbon, as in commercial cobalt, is to increase the compressive strength above 175,000 lbs. per sq. in. for the addition of 0.060 to 0.30 per cent. of carbon. The yield-point is not greatly affected, but it is lowered from 5 to 10 per cent. for 0.060 to 0.30 per cent. of carbon for both annealed and unannealed metal. The effect of annealing commercial cobalt is to lower its compressive strength—*e.g.*, unannealed specimens gave 183,000 lbs. per sq. in., and annealed samples 140,000 lbs. per sq. in. The compressive yield-point of commercial cobalt is similar to that of the purified metal, being 39,000 lbs. per sq. in. for unannealed samples, and 53,000 lbs. per sq. in. for annealed samples.

K. Honda gave $E=2.038 \times 10^{12}$ for Young's **elastic modulus** of 97.12 per cent. cobalt; and H. Tomlinson gave $E=2.005 \times 10^{12}$ for unannealed

cobalt, and $E=1.817 \times 10^{12}$ for the annealed metal. E. Widder gave $E=E_{20}\{1-0.0006803(\theta-20)\}$. H. Walker obtained, at different temp.:

	11.2°	35°	78°	100°	130°
$E \times 10^{12}$	1.479	1.476	1.475	1.473	1.471

K. Honda and co-workers studied the effect of magnetization, and observed that with a wire 64 cm. long, and 1 cm. diameter, in a magnetic field of H gauss:

H dE/E	Load = 1005 grms.			Load = 2830 grms.		
	100	250	500	100	250	500
	0.0025	0.0053	0.0077	0.0088	0.0028	0.0043

K. Honda observed for 97.12 per cent. cobalt the **torsion modulus** or **rigidity** $n=7.63 \times 10^{11}$ to 7.71×10^{11} ; E. Drago, 9.00×10^{11} ; and W. Sutherland gave 18,200 kgrms. per sq. mm. The effect of cooling near -110° was studied by L. Guillet and J. Cournot. K. Honda and co-workers observed for the effect of a magnetic field of H gauss:

H	100	200	400	600	800
dn/n	0.0005	0.0012	0.0021	0.0028	0.0031

P. W. Bridgman found the **compressibility** of purified cobalt at 30° to be $v/v_0 = -(5.39-2.1 \times 10^{-5}p)p \times 10^{-7}$, and at 75° , $v/v_0 = -(5.47-2.1 \times 10^{-5}p)p \times 10^{-7}$. T. W. Richards found the mean change in vol. by 0.987 atm. press. is 0.27. P. W. Bridgman estimated the coeff. of compressibility to be $\beta=0.0650$; and L. H. Adams gave $\beta=0.0655$, and for β/p , -0.0114 . T. W. Richards gave 510 kilomegabars, and R. F. Mehl, 510 kilomegabars for the **internal pressure**; and for the maximum disruptive internal press., 1870 kgrms. per sq. mm. T. W. Richards gave 329,000 megabars for the internal press. G. A. Tomlinson discussed the nature of the cohesive press. R. von Dallwitz-Wegner gave 338,670 atm. for the cohesion press. at 0° , and 305,728 atm. at 100° . E. Drago studied the internal friction of cobalt wires. J. F. Chittum studied the **surface energy**.

W. F. Barrett⁵ found that the **velocity of sound** in cobalt is 14.2 (air unity); and A. Masson gave 4724.4 metres per second.

H. Fizeau⁶ found the coeff. of **thermal expansion** of compressed cobalt, reduced by hydrogen, to be 0.041236 at 40° , and 0.041244 at 50° . A. Quadrio-Curzio gave 0.04181 between 25° and 300° ; and H. Masumoto and S. Nara, 0.041279 between 30° and 100° . E. P. Harrison gave for the value of α between 0° and 300° , $\alpha=(1280+0.75\theta+0.0035\theta^2) \times 10^{-8}$. A. E. H. Tutton gave $\alpha=0.041208+0.07128$ between 6° and 121° . Observations were also made by E. van Aubel. R. von Dallwitz-Wegner gave for the coeff. of cubic expansion, 0.04362 at 0° , and 0.04401 at 100° . W. F. Barrett observed that an abrupt expansion occurs at a stage in the cooling of an incandescent wire. A. Schulze observed that the coeff. of thermal expansion of technically pure cobalt between 0° and 20° , 100° , 300° , and 400° are respectively 0.041255, 0.041357, 0.041437, and 0.041511. There is a sudden expansion between 451° and 452° due to a transition point, and on cooling, the transition is delayed to temp. as low as 100° . H. Masumoto found that the thermal expansion of one sample of cobalt has an abrupt change at 442° , and at 427° and 477° in other samples; and on cooling there is an abrupt contraction at 360° to 403° —Fig. 3. These changes correspond with an allotropic change in the metal which occurs at 447° on the heating curve, and at 403° on the cooling curve. The presence of iron or other impurities lowers the transition temp. F. L. Uffelmann's values of the coeff. of thermal expansion on heating and cooling curves are indicated in Fig. 4. G. A. Tomlinson discussed some interatomic relations of the thermal expansion; T. W. Richards, the relation between the inner press. and the coeff. of thermal expansion; and A. Denizot, the relation between the sp. ht. and compressibility and the coeff. of thermal expansion. T. M. Lowry and R. G. Parker observed a slight permanent contraction after annealing cobalt filings at 100° .

W. F. Barrett found that the **thermal conductivity** of cobalt is 0.172 when that

of silver is unity. According to K. Honda, the thermal conductivity of cobalt is 0.1653 cal. per degree per cm. per sec. at 30°; and H. Masumoto gave 0.1299 cal. per degree per cm. per sec. at 30°.

P. L. Dulong and A. T. Petit⁷ gave 0.1067 for the **specific heat** of cobalt. H. V. Regnault gave 0.10674 for the sp. ht. of cobalt between 14° and 97°; and for

FIGS. 3 and 4.—The Thermal Expansion of Cobalt.

other samples, 0.10094 to 0.10727. W. F. Barrett gave 0.1070 between 15° and 100°; A. de la Rive and F. Marcet, 0.1172 between 5° and 15°; and W. A. Tilden found for temp. between 15°:

Sp. ht.	-182°	-78°	100°	185°	350°	435°	550°	630°
	0.0822	0.0939	0.1030	0.1047	0.1087	0.1147	0.1209	0.1234

and S. Umino gave for the mean and true sp. hts. of cobalt, the following results:

	100°	200°	300°	400°	450°	500°	600°	800°	900°	1000°
Mean.	0.1089	0.1107	0.1124	0.1145	0.1160	0.1185	0.1214	0.1298	0.1337	0.1378
True .	0.110	0.114	0.118	0.128	0.135	0.135	0.140	0.160	0.170	0.181

	1100°	1150°	1200°	1250°	1300°	1350°	1400°	1520°	1550°	1570°
Mean.	0.1420	0.1455	0.1480	0.1503	0.1527	0.1562	0.1579	0.2067	0.2079	0.2083
True .	0.199	0.213	0.203	0.208	0.213	0.219	0.225	0.265	0.265	0.265

The results are plotted in Fig. 5. There is a transformation point at 470°, and the ferromagnetic transformation at a higher temp., so that the curve has two maxima.

In the paramagnetic range, the sp. ht. curve is almost linear up to the m.p. The true sp. ht. of the molten metal does not vary with temp. H. E. Schmitz gave 0.0840 for the sp. ht. of cobalt between the b.p. of oxygen and 0°, and 0.10795 between 0° and 100°; H. Schimpff, 0.1030 between 17° and 100°; 0.0942 between 17° and 79°, and 0.0818 between 17° and -190°; T. W. Richards and F. G. Jackson, 0.828 between 19.6° and -185.9°; H. Copaux, 0.104 between 20° and 100°; and J. Pionchon gave 0.145063 at 500°; 0.184556 at 800°; and 0.204 at 1000°; and for the true sp. ht., c , at 0° and 890°, $c = 0.10584 + 0.0457334\theta + 0.07658281\theta^3$; and between 890° and 1150°, $c = 0.124 + 0.00008\theta$. P. Schübel gave 0.1042 between 18° and 100°, and 0.1220 between 18° and 600°; H. T. Kalmus and C. H. Harper, 0.1053 between 15° and 100°; A. Göbl, 0.0933 between 0° and -79°; 0.1041 between 0° and 100°; 0.1279 between 0° and 800°; and 0.1455 between 0° and 1187°; T. W. Richards and F. G. Jackson, 0.0828 between 20° and -188°; and J. Dewar, 0.0207 between -196° and -253°.

The **atomic heat** thus ranges from 1.22 in the vicinity of -253° to 8.58 in the vicinity of 1187°.

FIG. 5.—The Specific Heat of Cobalt.

H. E. Schmitz gave 4.96 at -85° , and 6.37 at 60° . I. Maydell gave for the at. ht. $A=8.720-938.9(\theta+352)^{-1}$. E. D. Eastman and co-workers calculated $C_p-C_v=0.13$ cal. per degree per mol. G. Tammann and A. Rohmann found for the heat capacity, $-C_{100}$ cal. per gram-atom between :

	-200° to -100°	-100° to 0°	0° to 100°	100° to 200°	200° to 300°	300° to 400°	400° to 500°
C_{100}	451.71	536.04	612.40	641.59	656.93	681.10	705.87

Observations were made by P. Oberhoffer and W. Grosse, F. Simon and M. Ruhemann, F. Wüst and co-workers, and J. F. Shadgen. J. R. Ashworth studied the relations between the thermal and magnetic constants of cobalt; A. H. Stuart, the relations between the elastic constants and the sp. ht.; G. A. Tomlinson, some interatomic relations of the sp. ht.; J. Perry, relations with the at. wts.; W. M. Latimer, and E. D. Eastman and co-workers, the thermal energy and the electrons; and J. Dorfmann and R. Jaanus, the change in the sp. ht. at the Curie point.

According to R. Pictet,⁸ cobalt has a **melting-point** of 1500° ; T. Carnelley, and P. H. van der Weyde, 1800° ; W. Guertler and G. Tammann, 1505° to 1528° ; H. Copaux, 1530° ; E. M. Terry, 1485° ; G. K. Burgess, 1464° for 99.95 per cent. cobalt; G. K. Burgess and R. G. Waltenburg, 1477° to 1478° ; A. L. Day and R. B. Sosman, 1489.8° ; W. R. Mott, 1489.8° ; U. Raydt and G. Tammann, 1480° ; K. Hiege, 1525° ; J. Jahn, 1565° ; H. T. Kalmus and C. H. Harper, 1478° ; V. A. Nemiloff, 1480° ; R. Ruer and K. Kaneko, 1491° ; K. Friedrich, 1494° ; R. Sahmen, and W. A. Wahl, 1493° ; S. Umino, 1489° ; and A. G. C. Gwyer, 1491° . W. Guertler and M. Pirani gave 1490° for the best representative value; and L. I. Dana and P. D. Foote, 1480° . Other observations were made by F. Wever and U. Haschimoto, and G. Boeher. W. A. Lampadius made a determination on a very impure specimen. W. Guertler and G. Tammann observed that the presence of iron has very little influence on the m.p. of cobalt. R. C. Smith found that cobalt filings sintered at 200° , and precipitated cobalt at 500° . W. A. Wahl observed that molten cobalt is readily undercooled as much as 216° below its f.p., and solidification then occurs suddenly. At first molten cobalt readily attacks porcelain, but once the oxide has been removed, subsequent fusions do not cause any attacks. T. Carnelley discussed the relation between the m.p. and the coeff. of thermal expansion; W. Crossley, the relation between the m.p. and the at. vol.; G. A. Tomlinson, some interatomic relations of the m.p.; E. Kordes gave 2.65 for the change of entropy on melting; and W. Braunkbek, the effect of melting on the space-lattice.

As indicated previously, J. Pionchon observed an **allotropic transformation** at 300° ; and, according to I. I. Schukoff, there is a magnetic transformation or **transition point** at 985° whereby the magnetic metal becomes non-magnetic; W. Guertler and G. Tammann said that the transformation occurs at 1150° . For Lord Kelvin's (W. Thomson's) observation on the relation of the phenomenon to the law of transformation of energy, *vide* iron.

According to H. Moissan, cobalt is less volatile than nickel, so that under similar conditions in the electric-arc furnace, only 20 grms. of cobalt were distilled during the distillation of 50 grms. of nickel. O. Ruff and F. Keilig gave 2415° for the **boiling-point** of cobalt, or 2375° at 30 mm. press. W. R. Mott calculated 2900° . O. Ruff and co-workers found that the metal saturated with carbon begins to boil at 2500° and about 40 mm. press. R. W. Millar gave 1885° at 1 mm. press., 2635° at 100 mm., 3050° at 500, and 3185° at 760 mm.; and for the **vapour pressure** of the liquid, $\log p = -1.865 \log T - 18610T^{-1} + 14.881$. F. Wüst and co-workers⁹ found the latent **heat of fusion** of cobalt to be 58.2 cal. per gram., or 3.44 Cal. per gram-atom at 1478° . J. W. Richards calculated 68 cal. per gram. S. Umino obtained 67.00 cal. per gram for the latent heat of fusion. E. Rabinowitsch and E. Thilo gave 0.15 volt for the heat of fusion; 3.94 volts for the heat of vaporization; and 4.09

volts for the heat of sublimation when 1 volt=23 Cals. The subject was studied by E. Kordes; and the relation between the heat of fusion and the vibration frequency, by W. Herz.

J. Thomsen¹⁰ found the **heat of dissolution** in hydrochloric acid to be $(\text{Co}, 2\text{HCl}, \text{aq.}) = 15.07$ Cals.; and in sulphuric acid, $(\text{Co}, \text{H}_2\text{SO}_4, \text{aq.}) = 19.71$ Cals. According to W. G. Mixter, the **heat of oxidation** to amorphous cobaltous oxide is $(\text{Co}, \frac{1}{2}\text{O}_2) = 50.5$ Cals., and to the crystalline oxide, 57.5 Cals.; whilst $(3\text{Co}, 2\text{O}_2) = 193.4$ Cals. Z. Shibata and I. Mori gave $(\text{Co}, \frac{1}{2}\text{O}_2) = 57,234$ cal. S. Umino found that the **heat of transformation** of cobalt from the hexagonal close-packed to the face-centred cubic lattice amounts to about 1.185 cal. per gram, or to 1.16×10^{-22} cal. for 1 molecule of cobalt. The magnetic transformation requires about 2.195 cal. per gram, or 2.14×10^{-22} cal. per molecule. E. D. Eastman, and G. N. Lewis and co-workers gave 7.2 cal. per degree at 25° for the **entropy** of cobalt. B. Bruzs, K. K. Kelley, W. Herz, R. D. Kleeman, and W. M. Latimer discussed this subject. R. von Dallwitz-Wegner discussed the **free energy**. Z. Shibata and I. Mori gave -51,612 cal. for the free energy of the reaction at 25.1°. H. Masumoto found a marked absorption of heat occurs at 427° on a rising temp., as α -cobalt passes to β -cobalt, and an evolution of heat at 360° on a falling temp. S. Umino calculated from the sp. ht. curves of 98.135 per cent. cobalt, that the heat of transformation is 1.01 to 1.08 cal. per gram at 460°. Observations on the subject were made by J. Maydel; and U. Dehlinger discussed the changes of energy during the transformation.

For the colour of cobalt, *vide supra*. H. du Bois and H. Rubens¹¹ found the **index of refraction**, μ , for electrolytic cobalt for light of wave-length, λ , to be:

λ	.	.	.	4310	4860	5393	6440	6700
μ	.	.	.	2.10	2.39	2.76	3.10	3.22

The **absorption coefficient**, and the **reflecting power**, R , given by R. S. Minor, are:

λ	.	2313	2573	2749	2981	3467	3950	4500	5000	5500	5893
k	.	1.43	1.81	2.14	2.33	2.47	2.91	3.42	3.71	3.90	4.04
μ	.	1.10	1.25	1.41	1.50	1.54	1.63	1.79	1.93	2.05	2.12
R	.	31.8	39.7	45.7	48.7	51.1	57.7	63.3	65.5	66.6	67.5

L. R. Ingersoll gave:

λ	.	7500	8700	1.00 μ	1.25 μ	1.50 μ	1.75 μ	2.00 μ	2.25 μ
k	.	4.85	5.37	5.73	6.30	6.73	6.81	6.95	7.18
μ	.	2.71	3.18	3.63	4.50	5.22	5.53	5.63	5.65
R	.	71.0	72.5	73.3	74.3	75.1	75.1	75.7	76.5

Observations were also made by A. Q. Tool, C. Zakrzewsky, I. C. Gardner, A. Kundt, A. Pflüger, G. Quincke, W. Voigt, and D. Shea. C. A. Skinner and A. Q. Tool discussed the optical properties of thin films of cobalt; and H. Behrens, the double refraction of films obtained by spluttering. W. W. Coblentz gave for the reflecting power:

λ	.	1.06 μ	1.71 μ	3.06 μ	3.96 μ	5.24 μ	6.75 μ	8.02 μ	9.38 μ	10.49 μ	12.03 μ
R	.	67.5	71.5	76.7	80.7	86.2	92.7	95.8	96.4	96.8	96.6

and observations were also made by W. W. Coblentz and R. Stair, E. O. Hulbert, A. Q. Tool, R. S. Minor, P. Drude, L. R. Ingersoll, A. Hunke, A. Heydweiller, A. Bromer, and K. Fajans and H. Kohner. H. Geisler studied the anomalous dispersion; and A. Kundt, the absorption of light by thin films.

H. Knoblauch found the **polarization angle** for ultra-red heat rays to be 79.00; and 72.50 for yellow-light. E. Hirsch studied the circular polarization. J. H. Gladstone gave 10.4 for the **refraction equivalent**, and 0.177 for the sp. **refractive power**. W. J. Pope gave 13.18 for the refraction equivalent of cobalt; and the scattering of light by cobalt-blue was studied by G. I. Pokrowsky.

C. L. Utterback¹² measured the total **radiation energy**, E , of cobalt at $T^\circ \text{K.}$, and found that $E=c_1T^{5.20}$ for temp. between 672°K. and 1320°K. ; and $E=c_2T^{4.62}$, between 1380°K. and 1590°K. There is a rapid change in the emission near the transformation point, 1348°K. , at which temp. there are changes in the susceptibility, permeability, resistance, sp. ht., and thermal expansion. G. K. Burgess and R. G. Waltenburg found that with light of wave-length 0.65μ , the emissive power, E , for cobalt near its m.p. is 0.36 for the solid, and 0.37 for the liquid. G. R. Green-slade determined the effect of temp. on the emission of energy.

The **Kerr effect** was studied by E. van Aubel,¹³ H. Behrens, H. du Bois, W. Dziewulsky, P. D. Foote, E. H. Hall, L. R. Ingersoll, A. Kundt, J. G. Leatham, P. Martin, C. A. Skinner and A. Q. Tool, C. Snow, and W. Voigt; and the rotation of the plane of polarization by passage through thin layers of cobalt in a magnetic field, the so-called **Faraday effect**, by H. Behrens, H. du Bois, C. J. Gorter, E. Hirsch, A. Kundt, W. Lobach, E. Miescher, C. A. Skinner and A. Q. Tool, and W. Voigt.

Cobalt gives no distinctive coloration to the colourless flame; but the **flame spectrum** of cobalt has been examined by A. Gouy,¹⁴ J. N. Lockyer, E. Diacon, L. de Boisbaudran, W. N. Hartley, W. N. Hartley and H. Ramage, C. de Watteville, A. Hagenbach and H. Konen, J. M. Eder and E. Valenta, G. D. Liveing and J. Dewar, J. Meunier, H. Auerbach, A. Harnack, and E. N. da C. Andrade. A. K. Russanoff studied the acetylene flame spectrum of nickel. The **spark spectrum** shows a number of lines and, according to J. Formanek, the more important of which are 5641 in the yellowish-green; 5483— ϵ , Fig. 6—5353 and 5340— α , Fig. 6—5280, 5267— β , Fig. 6—5212— δ , Fig. 6—and 5154 in the green; 4868— γ , Fig. 6—4840— ζ , Fig. 6—4815 and 4793 in the blue; 4533 in the indigo;

FIG. 6.—The Spark Spectrum of Cobalt.

and 4119 in the violet. The green double lines, α and β , are characteristic, and so also are the blue lines, γ and ζ , and the green line, ϵ . The spark spectrum was examined by W. E. Adeney, L. and E. Bloch, L. de Boisbaudran, R. Capron, G. C. Ciamician, E. Demarcay, J. M. Eder, J. M. Eder and E. Valenta, F. Exner and E. Hatschek, J. H. Findlay, H. Finger, A. Hagenbach and H. Konen, W. N. Hartley, W. Huggins, E. O. Hulburt, G. Kirchhoff, W. Kraemer, G. D. Liveing and J. Dewar, J. N. Lockyer, O. Lohse, F. McClean, W. A. Miller, J. Parry and A. E. Tucker, J. H. Pollok, J. H. Pollok and A. G. G. Leonard, T. R. Robinson, S. P. de Rubies, T. Takamine and S. Nitta, and R. Thalén. W. F. Meggers, W. F. Meggers and F. M. Walters, and E. O. Hulburt studied the spark spectrum under water.

The **arc spectrum** was studied by Lord Blythwood and W. A. Scoble, K. Burns, A. Cornu, F. Dhein, F. Exner and E. Hatschek, J. H. Findlay, C. E. Greider, S. Hamm, B. Hasselberg, C. Horner, J. Janssen, A. Krebs, G. D. Liveing and J. Dewar, J. N. Lockyer, J. C. McLennan and co-workers, H. M. Randall and E. F. Barker, H. A. Rowland, S. P. de Rubies, H. Slevogl, L. Stütting, T. Takamine and S. Nitta, W. Vahle, and F. M. Walters. The spectrum in the discharge tube with a glowing cathode resembles the arc spectrum; and it was examined by M. Kimura and G. Nakamura, J. H. Pollok, C. Wali-Mohammad, and L. Janicki.

The **absorption spectrum** of the vapour of cobalt was examined by J. N. Lockyer and W. C. Roberts-Austen, and W. F. Meggers and co-workers; the spectrum of gaseous explosions, by G. D. Liveing and J. Dewar; and the spectrum of cobalt in the electric furnace, by F. Dhein, G. A. Hemsalech, and A. S. King. The ultra-

violet spectrum was examined by V. Schumann, J. M. Eder, F. Exner and E. Hatschek, R. J. Lang, J. H. Findlay, E. Bayle and L. Amy, R. Volterra, L. and E. Bloch, T. Takamine and S. Nitta, J. C. McLennan and co-workers, R. G. zu Dohna, and H. Becquerel; and the **ultra-red spectrum**, by W. F. Meggers and C. C. Kiess, Lord Blythwood and W. A. Scoble, L. Stütting, and H. M. Randall and E. F. Barker. The effect of *pressure* on the spectral lines of iron was studied by W. J. Humphreys, C. D. Liveing and J. Dewar, W. B. Anderson, H. Finger, and H. Konen and H. Finger; the effect of *temperature*, by H. Auerbach, and W. N. Hartley; the *intensity* of the lines by W. Clarkson, P. W. Merrill, G. Nakamura, L. S. Orstein and co-workers, and L. S. Orstein and T. Bouma; the explosion spectrum, by H. Nagaoka and co-workers; the effect of the *oscillating discharge*, by G. A. Hemsalech; the effect of the *self-induction*, by G. A. Hemsalech, and P. B. Huber; the *anomalous dispersion*, by H. Geisler; the *enhanced lines*, by M. Kimura and G. Nakamura, and J. N. Lockyer; the effect of the *medium*, by H. Finger, P. B. Huber, W. B. Anderson, T. R. Robinson, G. A. Hemsalech, A. Schuster and G. A. Hemsalech, and H. Konen and H. Finger; the effect of a *magnetic field*—the **Zeeman effect**—by J. M. Graftdyk, S. Rybar, G. J. Elias, C. Wali-Mohammad, P. A. van der Harst, J. Kunz, F. M. Walters, J. H. Findlay, and J. H. van Vleck and A. Frank; *current strength*, etc., by M. Kimura and G. Nakamura; *reversed spectra*, W. F. Meggers, and A. Cornu; the *energy* of arc and spark spectra, by A. Pflüger; and the effect of an *electric field*—the **Stark effect**—by J. A. Anderson, M. Kimura and G. Nakamura, T. Takamine, and H. Nagaoka and Y. Sugiura. The *ultimate rays* were discussed by A. de Gramont, L. S. Orstein and T. Bouma, W. R. Mott, J. Bardet, F. Löwe, L. de Boisbaudran, H. N. Russell, E. Bayle and L. Amy, T. Negresco, M. Catalan and K. Bechert, W. F. Meggers and C. C. Kiess, and W. N. Hartley and H. W. Moss. The qualitative analysis of mixtures with cobalt was discussed by J. Parry and A. E. Tucker, A. Schleicher, and W. Gerlach and K. Ruthardt; and the quantitative analysis, by F. Twyman and C. S. Hitchin. The *structure and regularities of the line spectrum* of cobalt was studied by E. von Angerer and G. Joos, K. Bechert, C. G. Bedreag, M. C. W. Buffam and H. J. C. Ireton, B. Cabrera, W. M. Cady, M. A. Catalan, M. A. Catalan and K. Bechert, G. Ciamician, C. R. Davidson and F. J. M. Stratton, J. H. Findlay, R. C. Gibbs and H. E. White, S. Goudsmit, A. de Gramont, W. N. Hartley, F. Hund, L. Janicki, C. C. Kiess and O. Laporte, M. Kimura and G. Nakamura, O. Laporte, O. Laporte and W. F. Meggers, O. Laporte and A. Sommerfeld, W. F. Meggers, W. F. Meggers and C. C. Kiess, W. F. Meggers and F. M. Walters, R. A. Merrill, K. R. More, F. P. Mulder, A. A. Noyes and A. O. Beckman, P. G. Nutting, L. S. Orstein and T. Bouma, E. Paulson, R. Rudy, S. Rybar, H. N. Russell, M. N. Saha and B. B. Ray, M. Sawada, A. W. Smith and M. Muskat, C. P. Snow and F. I. G. Rawlins, L. A. Sommer, N. K. Sur, N. K. Sur and K. Majumder, I. Tamm, C. Wali-Mohammad, and F. M. Walters. No **series spectra** have been detected. A. T. Williams discussed the relation between valency and multiple spectra.

Red, aq. soln. of cobalt chloride become violet at 100°. The phenomenon was studied by J. Bersch,¹⁵ and J. Kallir. With conc. hydrochloric or sulphuric acid, the colour of the soln. becomes blue, and this the more readily, the higher is the temp. The red crystals of the hexahydrate, $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$, when heated, lose water, forming a lower hydrate, and the colour changes to violet-red, or bluish-violet. The anhydrous salt is pale blue. Aq. soln. of cobalt chloride can be red, violet, or blue. The colour depends on the temp. and conc. Red, aq. soln. become blue when mixed with the metal chlorides. The chlorides of calcium and magnesium are specially active, so that, even at ordinary temp., they change the colour to violet or blue. Hydrochloric acid and sodium chloride are not so active, but they enable the blue colour to appear at a lower temp. than is the case with soln. of cobalt chloride alone. The chlorides of zinc, mercury, antimony, tin, etc., act in the converse way and favour the change of colour from blue or violet back to the original red. Conc. soln. in methyl or ethyl alcohol are blue.

According to J. Formanek, the **absorption spectrum** of aq. rose-coloured soln. of cobalt chloride or nitrate, suitably diluted, has a strong, green band at 5160—Fig. 7; and two very weak bands at 4795 and 4610, which are not visible in dil.

FIG. 7.—The Absorption Spectra of Cobalt Salt Solutions.

soln. Defining the mol. extinction coeff., A , by the equation $I = I_0 10^{-Acd}$, where I_0 denotes the original intensity of the light, and I the final intensity after passing through d cm. of soln. containing C mols. of salt per litre, R. S. Houstoun and co-workers found that the mol. extinction coeff., A , is a function of the wave-

FIG. 8.—The Absorption Spectra of Aqueous Solution of Cobalt Salts.

length, λ , as indicated for soln. of different cobalt salts, in Fig. 8. The value of the coeff., A , varies with the concentration, C , of the soln.; and also with the temp. The results with the chloride for cold, dil. soln., cold, conc. soln. and hot, conc. soln. are illustrated by Fig. 9. W. J. Russell observed a great similarity in the absorption spectra of fused mixtures of cobalt and chloride and alkali chlorides, of blue soln. of cobalt chloride in hydrochloric acid, of conc. soln. of cobalt chloride in methyl, ethyl, and amyl alcohols, glycerol, and various esters. The results were in all cases ascribed to the presence of free, anhydrous cobaltous chloride. The spectra of aq. soln. varied with the concentration; saturated soln. gave a spectrum with bands at $\lambda=610$ and 625 characteristic of the anhydrous chloride, whilst dil. soln. gave a band between $\lambda=550$ and 485 , and this was ascribed to the hydrated chloride. W. N. Hartley found that the increase in ab-

sorption at the red-end of the spectrum with a rise of temp. is clearly shown by sat. soln. of cobalt chloride either alone or admixed with calcium chloride. The

general results show that soln. of cobaltous chloride in hydrochloric acid and in sat. soln. of calcium chloride contain something which is also produced in conc. aq. soln. with a rise of temp. The question arises: what is this something?

Several attempts have been made to explain the colour phenomena of the cobalt salts. The simple hydration theory was discussed by A. Étard, R. A. Houston and co-workers, A. Benrath, C. H. L. von Babo, H. Schiff, J. H. Gladstone, C. R. C. Tichborne, W. J. Russell, W. J. Russell and W. J. Orsman, A. Potilitzin, G. N. Wyruboff, G. Charpy, M. S. Wreusky, and W. N. Hartley; the molecular compound theory, by R. Engel, G. N. Wyruboff, H. le Chatelier, A. Chassevant, and F. Schlegel; the allotropic theory, by J. Bersch; the ionization theory, by W. Ostwald, W. C. D. Whetham, R. Salvadori, and N. Tarugi and G. Bombardini; the complex ion theory, by F. G. Donnan and H. Bassett, H. Bassett and H. H. Croucher, G. Rudorff, and H. G. Denham; and the hydrated ion theory, by P. Vaillant, G. N. Lewis, C. Mazzetti, H. C. Jones and co-workers, and A. Kotschubei. This subject is discussed in connection with the colour of cobaltous chloride. J. Piccard and E. Thomas studied the colour of cobalt ions; H. J. Witteveen and E. F. Farnau, the colours produced by the cobalt oxides.

FIG. 9.—The Effect of Temperature and Concentration on the Absorption Spectrum of Cobalt Chloride Solutions.

H. C. Jones and co-workers also examined the absorption spectra of cobalt salts, and tried to show that the gradual shift of an absorption band, as one salt is transformed into another by replacement of the acid radical, indicates that intermediate compounds are formed; but T. R. Merton showed that the alleged shift is only apparent, and is a consequence of the method of measurement employed in the work. T. Bayley discussed the relations of the absorption spectra salts of the iron family of elements. The absorption spectra of soln. were also observed by J. Angerstein, D. Brewster, W. Boehlendorff, J. Conroy, J. M. Hiebendaal, P. Dreisch, C. Kubierschky, G. B. Rizzo, C. P. Smyth, J. Landauer, M. Kahanowicz and P. Orecchioni, W. R. Brode, R. Samuel and co-workers, S. Hakomori, R. J. Macwalter and S. Barratt, B. E. Moore, W. N. Hartley, C. H. Wolff, S. Kato, A. Étard, A. Rosenheim and V. J. Meyer, T. Bayley, J. Moir, W. J. Russell, etc. The use of the absorption spectra for the qualitative analysis of members of the iron family of elements was discussed by H. W. Vogel, and J. Formanek; and the effect of press., by F. G. Wick.

According to J. Formanek, the soln. of cobalt chloride in absolute alcohol is sky-blue, and with conc. soln., the spectra have a broad absorption band extending into the red and yellow, and there are feeble bands at 5265 and 5150. By diluting the soln. with absolute alcohol, the feeble bands at 5265 and 5150 disappear, and the strong band in the red breaks up into small, feeble bands, 6245, 6063, 5906, 5720, and a strong band at 6648—*vide* Fig. 10. With very dil. soln., there are only the

FIG. 10.—The Absorption Spectra of Alcoholic Solutions of Cobalt Salts.

FIG. 11.—The Absorption Spectra of Acetone Solutions of Cobalt Salts.

strong band 6648, and the weak bands 6245 and 6063. The alcoholic soln. of cobalt nitrate is reddish-violet, and like the aq. soln. of cobalt nitrate, it has a strong, broad

band about 5240 , and in conc. soln. only, feeble bands at 4830 and 4620 . R. A. Houstoun and co-workers' results for soln. of cobalt salts in alcohol and in acetone are summarized in Figs. 10 and 11. The absorption is greater in these soln., and the results are more characteristic of the molecule than is the case with

FIG. 12.—The Effect of Water on Alcoholic Solutions of Cobalt Chloride.

$=0.9766$ and $C_2^2=3.3$; $C_1^3=0.9252$ and $C_2^3=5.75$; $C_1^4=0.8738$ and $C_2^4=9.35$; and $C_1^5=0.8224$ and $C_2^5=12.22$; etc. The results, Fig. 12, show that the maximum height of the band decreases approximately in the same ratio, and there is a slight displacement towards the red. For $C_1^7=0.514$ and $C_2^7=29.51$ there is no trace of this band, and the results are the same as with dil. aq. soln.

The cobalt chloride thus exists in two phases: one characterized by a band in the red (blue phase), and as water is added this passes into a phase characterized by a band in the green at $510\mu\mu$ (red phase). Since the maximum with the green band in aq. soln. not approaching saturation is about 6, and the maximum with the red band is about 232, the band in the green is observed by the side of the other band if more than one-tenth of the salt is in the blue phase. After applying the law of mass action to the results, it was concluded that in the red phase each cobalt chloride molecule is associated with approximately 15 mols. of water to form a polyhydrate. The absorption bands of cobalt chloride thus correspond with the anhydrous molecule ($680\mu\mu$), the hexahydrate ($550\mu\mu$ and $490\mu\mu$), and the polyhydrate. W. Hardt also studied the spectra of alcoholic soln.

J. Formanek found that cobalt chloride forms a blue soln. with hydrochloric acid, and this gives a characteristic absorption spectrum, Fig. 13. A conc. soln.

FIG. 13.—Absorption Spectra of Cobalt Salts.

has bands at 5495 , 5294 , 5041 , 4885 , 4510 , and 4418 , besides a strong, broad band in the red, and one in the violet. The bands at 5041 and 4885 are scarcely visible; and those at 4510 and 4418 are inclined to merge into one another. With dil. soln., the narrow bands, observed with the conc. soln., disappear, and the broad band in the red breaks up into bands at 6933 , 6600 , 6415 (weak), 6236 , and 6090 . A very small proportion of cobalt chloride in conc. hydrochloric acid shows the absorption bands very clearly. W. R. Brode, and W. R. Brode and R. A. Morton showed that the principal absorption band of soln. of cobalt chloride in conc. hydrochloric acid consists of six superimposed component bands. The frequencies of the maximum of these bands and also of the bands in the blue and green regions are integral multiples of 12.28 . A soln. of cobalt bromide in hydrobromic acid shows similar bands, but with fundamental frequencies of 11.70 . A soln. of cobalt iodide in hydriodic acid also shows absorption bands, the frequencies of maximum absorption being integral multiples of a fundamental frequency of 10.79 .

When a neutral soln. of cobalt chloride is mixed with tincture of alkanna, a

violet soln. is produced, and besides the absorption spectrum of alkanna, it shows a feeble band at 6320. If ammonia be added, a new absorption spectrum appears with three bands: 6370, 5845, and 5405, Fig. 13. A small excess of ammonia may give a blue precipitate. With a soln. of cobalt nitrate, and tincture of alkanna, there is a weak band at 6290; and after the addition of ammonia, the band is displaced more to the right than is the case with cobalt chloride, and there are bands at 6354, 5832, and 5395.

A. N. Nikolopoulos, and R. Luther and A. N. Nikolopoulos showed that the absorption spectrum of the cobaltamines is dependent only on the composition of the complex. The replacement of NH_3 by NO_3 , H_2O , Cl , and Br in the complex causes a displacement of the absorption towards the red end of the spectrum; and the replacement of NH_3 by NO_2 produces a displacement towards the violet end. In accord with the electronic theory, the stability of analogous compounds is greater the further the absorption bands extend towards the violet, and the photochemical sensitiveness is greater, the steeper is the absorption curve. Y. Shibata and G. Urbain also found that, with the exception of the NO_2 -group, the negative radicals provoke a displacement of the less refrangible bands towards the red. The absorption spectra of the cobaltamines have two bands with minima near 2000 and 3000, and these are characteristic of the tervalent cobalt atom acting as a chromophore. Observations were also made by C. Schleicher, R. Samuel and co-workers, E. Valla, K. Matsuno, A. Uspensky and co-workers, F. W. Beyer, J. Lifschitz and E. Rosenbohm, J. Kranig, A. Gordienko, and J. Angerstein.

When a soln. of a cobalt salt is treated with ammonium thiocyanate, the liquid becomes dark red; and if amyl alcohol is added, the cobalt thiocyanate colours the alcoholic layer greenish-blue. The absorption spectrum of the conc. amyl alcoholic soln. has an intense, orange-yellow band; and on dilution the band breaks up into four others at 6258, 6044, 5807, and 5636—Fig. 13. If the soln. be still further diluted, the bands at 5807 and 5635 disappear. The presence of nickel, chromium, manganese, and zinc do not interfere with these reactions as a qualitative test for cobalt. The acetone soln. are similarly used as a qualitative test for cobalt.

According to J. Conroy, J. Formanek, and J. Moir, blue cobalt-glass, not too dark, furnishes an absorption spectrum, Fig. 13, with a broad, intense band extending into the red and yellow, and there is a broad, weak band at 5348, and one which is just perceptible at 4934. If a paler cobalt-glass be used, in place of the broad band in the red and yellow, there are two bands, 6560 and 5900, whilst the band at 5348 becomes weaker, and that at 4934 is no longer visible. This absorption spectrum is characteristic of cobalt-glass, and enables it to be distinguished from blue copper-glass; and it also enables artificial cobalt-blue sapphires to be distinguished from natural sapphires. W. Abney and E. R. Festing observed a band at 1.32μ in the ultra-red spectrum of cobalt-glass. Observations were also made by M. Luckeish, D. Starkie and W. E. S. Turner, S. Sugie, T. Dreisch, W. R. Brode, and J. W. Mellor.

H. Kulenkampf,¹⁶ and W. Duane and T. Shimizu studied the continuous **X-ray spectrum**. The K-series of the X-ray spectrum includes the lines $\alpha_1\alpha=1.785287$; $\alpha_2\alpha'=1.789187$; $\alpha_3\alpha_4=1.7774$; $\beta_1\beta=1.617436$; $\beta_2\gamma=1.60562$; and $\beta'=1.62011$. Observations were reported by S. K. Allison, A. H. Barnes, H. Beuthe, F. de Boer, D. K. Berkeley, D. M. Bose, D. Coster and M. F. Druyvesteyn, G. B. Deodhar, V. Dolejssek, V. Dolejssek and H. Filcakova, W. Duane and co-workers, S. Erikson, P. Günther and co-workers, E. Hjalmar, S. Idei, S. Kawata, B. Kievit and G. A. Lindsay, H. G. J. Moseley, B. C. Mukherjee and B. B. Ray, G. Ortner, S. Pastorello, M. Privault, B. B. Ray, O. W. Richardson and co-workers, M. N. Saha and B. B. Ray, N. Seljakoff and co-workers, N. Siegbahn and co-workers, N. Stensson, R. Thoraesus, J. Valasek, B. Walter, J. H. Williams, G. Wentzel, and S. Yoshida. The K-absorption limits observed by F. de Boer are for the metal, 1.6042 Å., for bivalent compounds, 1.6029 Å., and for ter-

valent compounds, 1.6022 Å. Observations were also made by S. Björck, N. Bohr and D. Coster, R. Brdica, V. Dolejšek and K. Pestrecoff, W. Duane and K. F. Hu, B. Kievit and G. A. Lindsay, B. C. Mukherjee and B. B. Ray, M. Siegbahn, E. C. Stoner, R. Thoraues, and B. Walter. The structure of the K-lines was examined by H. Lang, F. de Boer, B. Kievit and G. A. Lindsay, B. C. Mukherjee and B. B. Ray, B. B. Ray, and B. B. Ray and P. C. Mahanti. The L-series of X-ray spectrum included $\alpha, \alpha-\alpha_2\alpha' = 15.94$; $\beta, \beta = 15.62$; $\epsilon = 18.20$; and $\eta\eta = 17.77$. They were studied by S. Björck, N. Bohr and D. Coster, V. Dolejšek and K. Pestrecoff, H. Hirata, C. E. Howe, G. Kellström, H. Lang, B. C. Mukherjee and B. B. Ray, F. P. Mulder, M. Siegbahn and R. Thoraues, E. C. Stoner, C. H. Thomas, R. B. Witmer and J. M. Cook, S. Björck, W. Stenström, R. Thoraues, J. H. van der Tuuk, and B. Walter. The M-series were investigated by U. Andrewes and co-workers, S. Björck, N. Bohr and D. Coster, K. T. Compton and C. H. Thomas, M. Levi, B. C. Mukherjee and B. B. Ray, O. W. Richardson and co-workers, B. B. Ray and R. C. Mazumdar, E. C. Stoner, C. H. Thomas, and B. Walter; and the N-series by F. P. Mulder, and B. Walter. M. A. Valouch, and J. Palacios and M. Velasco studied the structure of the X-ray spectrum.

C. G. Barkla and C. A. Sadler¹⁷ studied the penetrating power or hardness of the **X-rays**, and in general it is greater, the greater is the degree of exhaustion of the tube, but for a given tube, it depends solely on the potential difference of the electrodes. The penetrability is generally proportional to the 5th power of the at. wt. of the radiator. If I_0 be the intensity of a parallel beam of homogeneous X-rays, incident normally on a plate of absorbing material, then, the intensity I at a depth x is $I = I_0 e^{-\lambda x}$. The values of the coeff. λ divided by the density, D , for different absorbers, when radiator is cobalt, are, for K-radiations:

	C	Mg	Al	Fe	Ni	Cu	Zn	Ag	Sn	Pt	Au
λ/D	7.96	63.5	71.6	67.2	67.2	75.3	91.5	314	392	281	306

Observations on the **absorption** of X-rays were also made by O. W. Richardson and F. S. Robertson, F. K. Richtmyer and F. W. Warburton, J. Veldkamp, C. G. Barkla, C. G. Barkla and V. Collier, H. T. Meyer, H. Richardson, E. Rupp, C. A. Sadler and A. J. Steven, L. H. Martin and K. C. Lang, O. Stelling, K. Grosskurth, and M. Siegbahn. The absorption coeff. λ , for K-radiation in gases under normal conditions, were measured by C. G. Barkla and V. Collier, and E. A. Owen:

	Air	H ₂ S	SO ₂	C ₂ H ₅ Br
λ	0.0165	0.181	0.20	0.407

Observations were also made by L. M. Alexander, T. E. Aurén, G. B. Bandopadhyaya, L. Benoist, W. L. Bragg and H. L. Porter, W. L. Bragg and J. West, H. Kulenkampff, A. Hébert and G. Reynaud, M. Ishino and S. Kawata, R. Ledoux-Lebard and A. Dauvillier, E. A. Owen, J. A. Prins, H. S. Read, F. K. Richtmyer and F. W. Warburton, M. Siegbahn, and K. A. Wingardh. The **scattering** of the X-rays was studied by R. W. Jones and G. W. Brindley, E. A. Owen, F. K. Richtmyer and F. W. Warburton, and K. A. Wingardh; the **reflection** of the X-rays, by J. A. Prins, E. Rupp, D. K. Berkey, and H. T. Meyer; the X-ray **fluorescence**, by C. G. Barkla, L. H. Martin, and W. Kossel; the secondary and tertiary X-rays, by C. G. Barkla; the production of X-rays, by C. S. Brainin, O. W. Richardson, and O. W. Richardson and F. S. Robertson; the production of X-rays by the α -rays of radium-A, and radium-C, by H. Richardson; long range particles, by G. Kirsch and H. Pettersson; and the effect of oxidation on the emission of X-rays by cobalt, by L. P. Davies.

The **vibration frequency**—vide 1. 13, 19—of cobalt has been calculated from various formulæ. C. Benedicks¹⁸ thus obtained values ranging from 7.7×10^{12} to 9.1×10^{12} ; C. E. Blom, 8.3×10^{12} ; A. F. Scott, 8.3×10^{12} ; H. S. Allen, 8.87×10^{12} ; W. Biltz, 6.2×10^{12} ; W. Herz, 8.12×10^{12} ; and F. Simon and M. Ruhemann, 1.26×10^{12} to 8.0×10^{12} . Calculations were also made from the entropy by S. Pagliani, and W. Herz; from the at. wt. and mol. vol., by A. Stein;

and from the hardness, cohesion, and thermal expansion, by C. Benedicks. K. F. Slotte studied the velocity of the molecules at 0°.

H. B. Wehlin¹⁹ observed that when cobalt is heated to a temp. where vaporization is appreciable, ions with a single charge are emitted, but no ions with a double charge were observed. M. N. Davis, L. P. Davies, and G. B. Welch studied the **photoelectric effect** of cobalt, and G. B. Welch gave 1365 Å. for the photoelectric threshold of cobalt; J. J. Weigle, T. Pavolini, L. P. Davies, U. Nakaya, and W. Frese studied the effect of occluded gases on the photoelectric effect. H. S. Allen, and W. Frese noted that oxidizing agents which make the metal passive also reduce the photoelectric sensitiveness. A. B. Cardwell found that as the temp. of a cobalt wire, in vacuo, is gradually raised, the sensitiveness for a photoelectric current is greater with undercooled, face-centred cubic cobalt than it is with ordinary close-packed, hexagonal cobalt. At a higher temp., the two curves coincide; and with a falling temp., the curve tends to a maximum which is not attained on the curve for a rising temp. The maximum thermionic current is about $\frac{1}{15}$ th as strong as the maximum photoelectric current; and it is probable that the thermionic work function is less for cubic than it is for hexagonal cobalt. The long-wave limit for the photoelectric emission of cobalt, having a face-centred cubic lattice, is between 2967 Å. and 3022 Å., and for cobalt with a close-packed hexagonal lattice, between 2757 Å. and 2967 Å. J. J. Weigle gave 3450 Å. O. Berg and P. Ellinger, G. L. Locher, T. Pavolini, and G. B. Welch studied the photoelectric emission of electrons from compressed metal.

A. Günther-Schulze studied the work of electron emission; E. Rupp, and F. Butavand, the absorption of electrons; M. N. Davis, F. Simon, K. Hayakawa, L. P. Davis, U. Nakaya, and W. Espe. the emission of electrons; A. Gehrts, and M. N. Davis, the reflection of electrons; and C. J. Davisson and L. H. Germer, the diffraction of electrons. W. J. Russell discussed the feeble action of cobalt on photographic plates in the dark; W. Merckens, the formation of hydrogen dioxide by silver bromide gelatine; artificial radioactivity, by E. Fermi and co-workers; and N. Piltschikoff, the emission of the so-called Moser rays capable of passing through paper, celluloid, gelatine, and aluminium, and of decomposing silver bromide. R. Robl observed no luminescence in ultra-violet light; and R. E. Nyswander and B. E. Cohn studied the effect of cobalt on the thermoluminescence of glass.

B. B. Ray and R. C. Mazumdar,²⁰ A. A. Noyes and A. O. Beckmann, and J. H. Findlay investigated the critical potentials of soft X-rays. H. N. Russell gave for the series and ionization potentials for singly-charged atoms, respectively, 7.81 and 17.2 volts; for neutral atoms, 8.25, 9.03, 7.32, and 6.92 volts; and for ionized atoms, 16.62, 15.84, and 17.04 volts. For the ionization potential of neutral atoms, R. N. Ghosh gave 8.52 volts; N. K. Sur, 8.51 volts; L. A. Sommer, 8.4 volts; H. N. Russell, L. Rolla and C. Piccardi, 7.81 volts; and M. A. Catalan, 7.8 volts. A. C. Davies and F. Horton, E. H. Hall, C. H. Thomas, and U. Andrewes and co-workers obtained a series of values for the critical voltages of cobalt; and O. W. Richardson and co-workers found that a sequence of these can be represented by $V=179.5-2357n^{-2}$ volts, where $n=4, 5, 6, 7, 8, 10$, and 12.

H. E. Watson and G. R. Paranjpe,²¹ and G. R. Paranjpe found that under comparable conditions the cathode fall of potential in neon is 150 volts; in helium, 161 volts; in argon, 184 volts; and in nitrogen, 259 volts. The results in hydrogen were irregular. A. Schaufelberger observed that the normal fall of potential in air thoroughly dried is 381 volts. A. Günther-Schulze, K. Meyer and A. Günther-Schulze, F. Schröter, V. Kohlschütter, and H. P. Walmsley studied the cathodic spluttering of cobalt—*vide supra*, colloidal cobalt. C. E. Guye and L. Zebrikow, H. Nagaoka and Y. Sugiura, and W. G. Cady studied the difference of potential in the electric arc between cobalt electrodes. M. Haitinger measured the intensity of the ultra-violet ray from the cobalt arc-light.

The **electrical resistance** of cobalt, measured by H. Copaux,²² is 5.5×10^{-6} ohm per cm. cube at 0° ; R. Ruer and K. Kaneko gave 6.4×10^{-6} ohm per cm. cube at room temp. for purified cobalt previously heated to 1150° and slowly cooled; C. G. Knott, 11.2×10^{-6} ohm per cm. cube at 100° , and 15.9×10^{-6} ohm at 200° ; whilst G. Reichardt found for 99.8 per cent. cobalt at 20° , $R = 9.73 \times 10^{-6}$ ohm per cm. cube, when heated to 160° , and $R = 9.94 \times 10^{-6}$ when not so heated. A. Schulze found for the sp. resistance of three samples with 99.2 per cent. of cobalt at 20° , $R = 0.056363$, 0.056480 , and 0.041352 respectively. H. T. Kalmus and C. Harper gave $R = 8.964 \times 10^{-6}$ ohm at 18° for 99.9 per cent. cobalt, and 9.035×10^{-6} for 98.71 per cent. cobalt previously heated to 800° in an atm. of carbon dioxide. H. Masumoto found 11.83×10^{-6} ohm at 30° for 99.46 per cent. cobalt, cast and annealed at 800° ; and K. Honda, 8.59×10^{-6} ohm at room temp. for 97.12 per cent. cobalt. J. C. McLennan and co-workers gave for purified cobalt heated 4 hrs. at dull redness in vacuo, 6.85×10^{-6} ohm at 20° , and when not so pre-heated, 8.07×10^{-6} ohm. L. Holborn said that the family iron, cobalt, and nickel is not only characterized by its ferromagnetism, but the *temperature coefficient* of the resistance is greater than with the other elements, being 0.003235 between -192° and 0° ; 0.00658 between 0° and 100° ; 0.00475 between 100° and 200° ; 0.004096 between 200° and 300° ; and 0.003426 between 300° and 400° ; P. W. Bridgman found 0.0033 between 0° and 100° ; G. Reichardt, 0.00326 between 0° and 150° ; H. Copaux, 0.0055 between 0° and 22° , and 0.0060 between 0° and 80° ; and H. T. Kalmus and C. Harper, 0.00357 between 0° and 100° . A. Schulze gave for the temp. coeff. 0.00522 between 15° and 25° , and 0.00592 between 0° and 100° ; and for another sample the respective values 0.00303 and 0.00264 were observed. J. T. MacGregor-Morris and R. P. Hunt, E. van Aubel, W. Broniewsky, and A. Matthiesen and C. Vogt, made some observations on this subject. H. Schimank calculated for cobalt at absolute zero, $R_0 = 0.8869$ ohm, and for the ratio $R_r : R_0$ at 273.09° K., 194.4° K., 81.8° K., and 20.2° K., the respective values 1.0000, 0.7500, 0.4603, and 0.3920. W. Meissner and co-workers measured the resistance at temp. down to -271.8° . If r denotes the ratio of the resistance R_r at the observed temp. to that of R_0 at 0° ; and r_{red} denotes the estimated value for the pure metal, then for two different samples of purified cobalt: I, heated at 500° in vacuo; and II, melted in vacuo, when R_0 for the former is 1.604×10^{-2} ohm, and for the latter, 1.324×10^{-4} ohm:

	0.16°	-184.84°	-186.08°	-194.60°	-195.22°	-252.59°	-271.49°	-271.84°
I { r . . .	1	—	0.1829	—	0.1516	—	0.0431	—
{ r_{red} . .	1	0.1509	0.1465	0.1158	0.1139	0.00384	0.0000	—
II { r . . .	1	0.1901	—	0.1588	—	0.05857	—	0.0624
{ r_{red} . .	1	0.1397	0.1355	0.1065	0.1047	0.0000	—	—

J. C. McLennan and co-workers gave for the resistance, R ohms, of aged and unaged cobalt:

	20°	-190°	-252.4°	-268.8°	-270.5°
$R \times 10^3$ { Unaged . . .	1.80	0.495	0.313	0.277	—
{ Aged . . .	2.11	0.382	0.143	0.140	0.140

W. Tuijn and H. K. Onnes found that cobalt did not show superconductivity at low temp. W. Meissner studied the subject.

R. Ruer and K. Kaneko observed no perceptible effect was obtained on the electrical resistance of cobalt by heating it to 1150° in an atm. of nitrogen. According to H. T. Kalmus and C. Harper, the effect of annealing wires of purified cobalt in vacuo at 350° for several hours by passing an electric current through the wire, is to decrease the resistance about 5 per cent. This is not so much as for some metals, e.g. aluminium, for which H. Gwercke found a decrease of 10 per cent. by annealing for 2 hrs. at 250° . The effect of annealing in an atm. of carbon dioxide is at first to increase the resistance, and afterwards, as the temp. rises to 800° , the sp. resistance falls. A drop from 10.1×10^{-6} to 9.35×10^{-6} ohm per cm. cube, occurs in the sp. resistance of cobalt wire of a high degree of purity annealed

in an atm. of carbon dioxide at 600° compared with one similarly annealed at 500° . The difference in the effects of annealing in vacuo and in a gaseous atm. shows that the sp. resistance is largely influenced by adsorbed or occluded gases. Like copper, and most metals, the sp. resistance of cobalt is greatly augmented by the presence of impurities. Less than 0.5 per cent. of impurity may treble the electrical resistance. The electrical resistance of commercial cobalt wires, unannealed after swaging, varies between 23.1×10^{-6} and 10.3×10^{-6} ohm per cm. cube. The effect of annealing by passing a current through the wire in vacuo is to reduce the sp. resistance. Annealing for 5 hrs. at 350° reduced the sp. resistance 14 per cent.; and by heating in an atm. of carbon dioxide the resistance is decreased. There is a sharp decrease in the resistance in a sample annealed at 600° compared with one similarly annealed at 500° . With 99.6 per cent. cobalt, with a resistance $R = 8.964 \times 10^{-6}$ ohm, at 18° , the values of R , after annealing 1 to 2 hrs. in an atm. of carbon dioxide, were :

Annealing temp.	400°	500°	600°	700°	800°
$R \times 10^6$	9.74 (17.7°)	10.11 (21.2°)	9.385 (15.4°)	9.333 (19.0°)	9.165 (16.5°)

A. Schulze found the sp. resistance of cobalt of a high degree of purity to be $R = 0.05636$ at 20° , and the temp. coeff. between 15° and 25° to be $\alpha = 0.00522$, and between 0° and 100° , $\alpha = 0.00592$. Between -192° and 500° , the temp. coeff. runs up from 0.00323 to 0.00592; falls down to 0.00342 with a maximum at about 50° ; between 400° and 500° , there is a transition, and breaks occur in the temp. resistance curve at 444° and 468° , or :

	0°	100°	200°	300°	400°	500°
R/R_0	1.0000	1.5922	2.3540	3.3183	4.4552	5.4340

For temp. in the vicinity of the temp. of magnetic transformation, A. Schulze gave the results summarized in Fig. 14, where the resistance R_0 at 0° is 0.057229 ohm, and for the ratio of the value R at θ° and the value at 0° , he gave R/R_0 unity at 0° , and :

	1298°	1254°	1208°	1166°	1114°	1067°	1018.5°	965.1°	898.7°
R/R_0	16.322	16.123	15.812	15.554	15.062	14.377	13.535	12.738	11.661

H. Masumoto found that the variation of the electrical resistance with temp., using different samples of cobalt, is interrupted by an abrupt change as the temp. rises between 442° and 477° , Fig. 15; and during cooling, a reverse change occurs

FIGS. 14 and 15.—The Electrical Resistance of Cobalt.

at 360° to 403° . These changes correspond with the transition temp.; and this temp. is lowered by the presence of iron, etc. H. B. Peacock measured the resistance of thin films, and found the resistance of films 11 to 16 $m\mu$, prepared by the condensation of the vapour, to be about 23 times its normal value; but if the films be preheated to 300° the normal value is obtained.

D. Foster compared the electrical and thermal conductivities. P. W. Bridgman

found that the effect of pressure is abnormally low; and he gave for the *pressure coefficient*:

	Resistance	Pressure Coefficient		
		At 0 kgrms.	At 12,000 kgrms.	Average 0 to 12,000 kgrms.
0°	1.0000	-0.0.941	-0.0.805	-0.0.873
50°	1.1825	-0.0.845	-0.0.755	-0.0.860
100°	1.3651	-0.0.745	-0.0.697	-0.0.726

A. Schulze also studied the effect of pressure. E. D. Williamson found the ratio of the resistance at 1 and 12,000 kgrms. per sq. cm. press. to be 0.9895. P. W. Bridgman observed that the effect of *tension* of 100 grms. on a cobalt wire 0.003 in. diam., is linear, with a tension coeff. of 9.94×10^{-7} at 30°, where the tension is measured in kgrms. per sq. cm. H. Tomlinson observed that the resistance of unannealed cobalt increases in a *magnetic field* by $\delta R/R = 0.05628$ per unit magnetizing force; P. McCorkle observed $\delta R/R = 0.004$ for $H = 1000$ gauss. G. Fae said that the resistance of a thin plate increases if the plane of the plate is parallel to the lines of magnetic force, and decreases if the plate is vertical to those lines, and the subject was studied by D. Goldhammer, and Y. Matsuyama. L. Grunmach and F. Weidert studied the effect of transverse magnetization on the electrical conductivity of cobalt, and found that the percentage decrease produced by a field-strength of 10,000 gauss is -0.53. L. Bloch, F. Simon, K. Höjendahl, and K. F. Herzfeld discussed the theory of the electrical resistance. E. Branly found that a Ag-Mica-Co condenser shows unipolar conductivity only after a long-continued passage of the current.

P. E. Shaw²³ and co-workers studied the **tribo-electricity** of cobalt and glass; and W. A. D. Rudge, the production of negatively charged dust when cobalt is spluttered in air in a brass tube. J. B. Seth and co-workers studied the e.m.f. developed by cobalt and steel in contact and in relative motion. L. Bernoulli, V. Fredericksz, and A. Hesehus discussed the position of cobalt in Volta's **contact series**. C. Drucker placed cobalt in the **electrochemical series** . . . Zn, Fe, Cd, Tl, Co, Ni, Pb . . .; and B. Neumann, . . . Zn, Cd, Fe, Co, Ni, Pb . . . G. Tammann gave for the potential series with normal chlorides: Mg, Mn, Zn, Fe, Cd, Tl, Co, Ni, Pb, Sn, Cu, Bi, Ag, Au; and for the heats of formation of the solid chlorides, Mg, Mn, Zn, Cd, Tl, Pb, Fe, Sn, Co, Ni, Cu, Bi, Ag, Au. M. M. Haring and E. G. van den Bosche found that cobalt is more electropositive than nickel. The subject was discussed by A. S. Russell and co-workers, H. T. S. Britton, and C. B. Gates.

In its electrochemical behaviour, cobalt occupies a position between iron and nickel. The normal **electrode potential** of cobalt was reported by R. Abegg²⁴ and co-workers to be for $\text{Co} \rightarrow \text{Co}^{++}$, -0.29 volt; for $\text{Co}^{++} \rightarrow \text{Co}^{+++}$, 1.8 volt; and for $\text{Co} \rightarrow \text{Co}^{+++}$, 0.4 volt; and A. B. Lamb and A. T. Larson obtained for cobalt in a soln. of cobaltous chloride, -0.237 volt for $\text{Co} \rightarrow \text{Co}^{++}$; and for $\text{Co}^{++} \rightarrow \text{Co}^{+++}$, they obtained 1.775 volts at 0°, 1.779 volts at 16°, and 1.817 volts at 25°, so that the temp. coeff. is 0.00169 volt. H. G. Denham and S. W. Pennycuik gave -0.247 volt; E. Müller and J. Janitzki, -0.292 volt; M. M. Haring and B. B. Westfall, -0.278 volt; and T. Heymann and K. Jellinek, -0.268 volt. Observations were also made by N. T. M. Wilshire, and M. le Blanc. G. Grube and O. Feucht obtained -0.52 volt for $\text{Co} \rightarrow \text{CoO}_2^{++}$ against a soln. of potassium cobaltite in 8N-KOH; and A. S. Russell and co-workers obtained for passive cobalt, 0.8 volt. B. Neumann gave for the electrode potential of cobalt in a normal soln. of the sulphate, -0.255 volt; chloride, -0.259 volt; nitrate, -0.196 volt; and acetate, -0.207 volt. H. N. Huntzicker and L. Kahlenberg studied the potential in soln. of salts of copper, silver, and nickel.

W. Muthmann and F. Fraunberger observed that the potentials of the iron family of metals are sensitive to the presence of oxygen; and a cobalt activated cathode has a high potential, attaining -0.034 volt in $N\text{-CoSO}_4$, at 20°, and this is the so-called air potential by cobalt. By polishing a cobalt rod, the potential

changes from -0.034 volt to -0.264 volt, and after lying in air a few seconds, -0.074 volt. After treatment cathodically in potash lye, the potential is -0.234 volt; when treated with conc. chromic acid, -0.076 volt; when treated as anode in a soln. of potassium thiocyanate, -0.104 volt; potassium cyanide, -0.074 volt; distilled water, -0.074 volt; and potash lye, 0.746 volt. G. Coffetti and F. Förster observed that a freshly-fractured electrolytic cobalt has, after a short time, the potential -0.25 volt in $N\text{-CoSO}_4$ at 20° , and this value is independent of the conc. of the Co^{++} -ions, so that the value is not dependent on the equilibrium $\text{Co} \rightleftharpoons \text{Co}^{++}$. R. Schildbach observed that the electrode potentials of cobalt powder in an atm. of nitrogen against $N\text{-CoCl}_2$ and $0.1N\text{-CoCl}_2$ are respectively -0.293 and -0.339 volt; and against $N\text{-CoSO}_4$ and $0.1N\text{-CoSO}_4$, respectively -0.316 and -0.339 volt compared with a normal hydrogen electrode. The sign refers to the cobalt electrode. With massive cobalt, the values are rather more positive—e.g., with $N\text{-CoSO}_4$, it is -0.288 volt. Cobalt powder charged with hydrogen gives considerably more negative values at first, which gradually change until the equilibrium potential is reached. When unpolarized cobalt is placed in a cold soln. of one of its salts, its potential is more positive than the equilibrium value, -0.121 volt, for example, but the equilibrium value is reached fairly quickly. Thus:

Time	2	7	22	42	66	140	240 mins.
E	-0.158	-0.216	-0.247	-0.284	-0.310	-0.319	-0.319 volt

From neutral soln., in an atm. of hydrogen, cobalt is deposited with quantitative current efficiency. The difference of potential between the electrode and the electrolyte is, however, much larger than the equilibrium value. The difference increases with the current density, and diminishes as the temp. rises, almost vanishing at 90° ; it is very much increased by the addition of small quantities of acid to the soln., and this effect is especially marked at a low temp. The subject was studied by M. M. Haring and E. G. V. Bosche.

E. Newbery found that the electrode potential of cobalt at 15° , under conditions where the effects due to occluded hydrogen are excluded, is 0.22 volt for $0.1N\text{-CoSO}_4$, 0.21 volt for $0.1N\text{-Co(NO}_3)_2$, and 0.15 volt for $0.1N\text{-CoCl}_2$. The low values for cobaltous chloride were attributed to the formation of a complex salt; and R. Abegg and S. Labendzinsky came to a similar conclusion. E. Newbery observed that the potential in the sulphate or nitrate soln. attains a constant value in a few hours owing to some surface change. When the soln. are stirred, the potential in sulphate soln. rises 0.13 volt, and in chloride soln., 0.07 volt; and when the stirring has ceased, the potential returns to its original value—at first rapidly and then slowly. G. B. Bonino and M. Bottini found that the potential of finely-divided cobalt electrolytically deposited on platinum, towards distilled water, rises in 16 hrs. from -0.625 volt to the constant value -0.705 volt. W. Muthmann and F. Fraunberger gave for the potential in soln. of potassium hydroxide (1 : 3), -0.024 volt; 30 per cent. chromic acid, 0.456 volt; 10 per cent. sulphuric acid, -0.124 volt; and 34 per cent. nitric acid, 0.226 volt. S. J. French and L. Kahlenberg measured the potential in $N\text{-KCl}$, and found that in hydrogen, the potential becomes more basic, reaching a maximum and then falling off; in nitrogen, the potential becomes more basic, and attains a maximum; and in oxygen, the potential becomes less basic, reaching a maximum and then falling off in bubbling gas, but it becomes more basic with the gas quiescent. L. Kahlenberg and J. V. Steinle observed the single potentials of cobalt in a soln. of $0.5N\text{-Na}_3\text{AsO}_4$ to be 0.127 volt; in $0.5N\text{-K}_3\text{AsO}_4$, 0.131 volt; and in $N\text{-KCl}$ sat. with arsenic trioxide, 0.126 volt. W. Hiltner and W. Grundmann studied the electrometric titration of the sulphate.

S. Labendzinsky found the **electromotive force** of the combination $\text{Co} : 0.5N\text{-CoCl}_2$ and $N\text{-KCl}$ against $\text{Hg}_2\text{Cl}_2 : \text{Hg}$, 0.592 volt; with $0.05N\text{-CoCl}_2$, 0.625 volt; with $0.5N\text{-CoSO}_4$ and $N\text{-Na}_2\text{SO}_4$, 0.622 volt; and with $N\text{-Co(NO}_3)_2$ and $N\text{-KNO}_3$, 0.588 volt. R. Schildbach studied some combinations with cobalt,

$N\text{-}0\cdot1N\text{-CoSO}_4$ or CoCl_2 , and a sat. soln. of potassium chloride and the calomel electrode, and of the cells $\text{Co} : \text{CoSO}_4 : N\text{-Na}_2\text{SO}_4 : \text{CuSO}_4 : \text{Cu}$. A. B. Lamb and A. T. Larson found for the combination $\text{Co} : M\text{-CoCl}_2 : N\text{-KCl}, \text{Hg}_2\text{Cl}_2 : \text{Hg}$, at 25° :

M	.	.	0.01	0.02	0.05	1.0	2.0
E	.	.	0.582	0.570	0.556	0.539	0.525 volt

They also measured combinations with the cobalt chloride mixed with aq. ammonia ; and H. G. Denham and S. W. Pennycuik, combinations with the cobalt chloride associated with potassium, magnesium, zinc, and aluminium chlorides. V. Regnaud studied the cell Co and HNO_3 and a cobalt salt against sulphuric acid and zinc amalgam and zinc. F. Streintz studied cells with cobalt and an aq. soln. of cobalt salt against a metal salt soln. and the corresponding metal—copper, silver, magnesium, zinc, cadmium, tin, and bismuth. B. Neumann observed with cobalt and a N -cobalt salt against a N -soln. of an indifferent electrolyte, $N\text{-KCl}$ and Hg_2Cl_2 , and mercury, the sulphate gave 0.541 volt ; the chloride, 0.545 volt ; the nitrate, 0.480 volt ; and the acetate, 0.556 volt ; W. Muthmann and F. Fraunberger studied cells with $N\text{-KCl}, \text{Hg}_2\text{Cl}_2$ and mercury against cobalt and soln. of cobalt sulphate ; potassium chloride, hydroxide, cyanide or thiocyanate ; or sulphuric, hydrochloric, nitric or chromic acid ; G. Coffetti and F. Förster, the cell $\text{Co} : N\text{-CoSO}_4 : 0\cdot1N\text{-KCl}, \text{Hg}_2\text{Cl}_2 : \text{Hg}$. A. von Oettingen, and S. B. Christy, the cell $\text{Co} : N\text{-KCy} : N\text{-KCl}, \text{Hg}_2\text{Cl}_2 : \text{Hg}$; and K. Zengelis, $0\cdot1N\text{-KCl} : N\text{-KCl}, \text{Hg}_2\text{Cl}_2 : \text{Hg}$ against cobalt and a soln. of cobalt sulphate and $0\cdot1N$ -soln. of potassium sulphide, aq. ammonia, potassium nitrite, sodium phosphate, potassium arsenate, or potassium cyanide. W. Hittorf examined cells with platinum and chromic acid against cobalt and soln. of sodium nitrate, sulphate, or acetate, or potassium dichromate. H. W. Toepffer found for the cell $\text{Co} : \text{CoSO}_4$ against $\text{NiSO}_4 : \text{Ni}$, 0.26 volt, and against $\text{FeSO}_4 : \text{Fe}$, 0.13 volt ; for $\text{Co} : \text{CoSO}_4$ and $(\text{NH}_4)_2\text{C}_2\text{O}_4$ against $\text{NiSO}_4(\text{NH}_4)_2\text{C}_2\text{O}_4$ and nickel, $-0\cdot25$ volt, and with iron in place of nickel—salt and metal— $0\cdot21$ volt ; and for $\text{Co} : \text{CoSO}_4$ and $(\text{NH}_4)_2\text{SO}_4$ against nickel and ammonium sulphate and nickel, $-0\cdot19$ volt, and with iron in place of nickel—salt and metal— $0\cdot18$ volt. Observations were also made by E. Oberer, K. Georgi, and N. P. Kazankin. G. B. Bonino and co-workers studied cells with cobalt against a cobalt salt and protein, egg-albumin, or blood-serum, against platinum. H. J. Blik-slager studied cells with cobalt against cobalt chloride and an alkali chloride against molten alkali chloride with a different proportion of cobalt chloride. A. C. Krueger and L. Kahlenberg studied the cells with cobalt and a soln. of gas in an electrolyte against the normal calomel electrode at 22° to 24° , and found :

	H_2	O_2	N_2	A	He
$N\text{-KCl}$	0.598	0.457	0.581	0.560	0.553
$N\text{-KOH}$	0.885	0.832	0.866	0.888	0.896
$N\text{-HCl}$	0.447	0.382	0.439	0.444	0.438

The **ionic mobility** of cobalt for $\frac{1}{2}\text{Co}^{++}$, was found by A. Heydweiller to be 43.0 at 18° ; E. Rona gave 47.7 at 18° ; A. Feiler, 51.0 at 18° ; W. Riedel gave for soln. with a mol per 20.8, 203.5, and 432 litres the respective values 0.6218, 0.6062, and 0.6040 ; W. Althammer gave 50.6 for the chloride, 51.4 for the bromide, and 50.9 for the iodide at 20° respectively for chloride, bromide and iodide soln. ; and C. Mazzetti gave :

	10°	20°	30°	40°	50°	60°
Ionic mobility	46	73	102	124	144	155

R. C. Cantelo and E. C. Payne gave 0.396 for the transport number of the Co^{++} -ion in $0\cdot233N\text{-CoSO}_4$, and 0.149 in $3\cdot994N\text{-CoSO}_4$. W. C. D. Whetham calculated the absolute velocity of the ions for a fall of potential of 1 volt per cm. to be $0\cdot0_422$ cm. per sec. for soln. of cobaltous chloride in alcohol ; and $0\cdot0_444$ cm. per sec. for alcoholic soln. of cobaltous nitrate. E. Gapon, and E. Newbery discussed the **hydration of the ions** of cobalt. W. Ostwald calculated the **heat of ionization**, $\text{Co} \rightarrow \text{Co}^{++}$, to be

73 kilojoules on the assumption that the heat of ionization $H_2=2H^+$ is zero. J. D. Bernal and R. H. Fowler calculated for the **ionization energy** of the Co^{++} -ion, 594 Cals. per gram-ion.

According to C. Luckow, when a neutral soln. of a cobalt salt is electrolyzed, cobalt is incompletely separated, but if acetic acid be present, or, according to A. Riché, if other acids be present, the separation is complete. A large excess of acid, however, hinders the electrodeposition of cobalt; but it is favoured by the presence of alkali acetates, citrates, tartrates, or oxalates; or of potassium cyanide, or sodium hydrophosphate, or pyrophosphate. This subject was studied by H. Kersten, and A. Job—*vide supra*, the extraction of cobalt. According to F. W. Skirrow, when a hydrofluoric acid soln. of a cobalt salt is electrolyzed, cobaltic oxide is formed, but this is not the case in sulphuric acid soln. He showed that the oxidizing action at the anodic depends on the potential. A. Coehn and co-workers observed that in dil. alkaline soln., anodic oxidation occurs with cobalt sulphate at 1.21 volts and with nickel sulphate at 1.3 volts; in dil. acidic soln., the oxidation occurs with cobalt sulphate at 1.52 volts, and not with nickel sulphate soln.; and in conc. acidic soln., the anodic oxidation does not occur.

M. le Blanc found the **deposition potential** of cobalt from $N-CoSO_4$ to be -0.444 volt, and G. Coffetti and F. Förster showed that in order to prevent the formation of hydroxide, at 20° , the soln. must be acidified. With a voltage of -0.55 to -0.61 , and a current density, D amp. $\times 10^{-4}$ per sq. cm.:

Current Density	11.3	22.7	45.5	93.0	182.0
N-Acid	0.0025	0.005	0.0075	0.01	0.02
Current yield	29	68	70.5	76.5	66 to 70 per cent.

R. Schildbach showed that in these observations the oxygen of the air should be excluded, since it acts as a depolarizer on the cathodic hydrogen. S. Glasstone studied the effect of the current density on the cathode potentials of cobalt in $N-CoSO_4$ at 15° , and found for current densities of D amp. $\times 10^{-4}$ per sq. cm.:

D	$0.1N-H_2SO_4$	$P_H=2.8$	$P_H=4.0$	$P_H=5.0$	$P_H=6.0$
0.14	-0.19	-0.17	-0.19	-0.22	-0.24
0.56	-0.22	-0.22	-0.34	-0.39	-0.44
1.4	-0.31	-0.42	-0.49	-0.56	-0.56
2.8	-0.36	-0.46	-0.56	-0.57	-0.57
5.6	-0.42	-0.51	-0.57	-0.59	-0.59
12.0	-0.49	-0.56	-0.59	-0.61	-0.61
40.0	-0.56	-0.57	-0.61	-0.62	-0.63
80.0	-0.57	-0.59	-0.62	-0.63	-0.64
160.0	-0.58	-0.60	-0.63	-0.64	-0.65

R. Schildbach studied the effect of current density and temp. on the deposition potential, and found, for neutral, and normal soln.:

D		0.4	1.4	5.7	22.7	45.5	182	
E	$N \cdot CoCl_2$	1°	—	-0.413	-0.431	-0.455	-0.474	-0.533
		20°	-0.361	-0.370	-0.380	-0.398	-0.414	-0.459
		50°	—	-0.335	-0.338	-0.345	-0.354	-0.390
		92°	—	—	—	—	-0.294	-0.337
	$N \cdot CoSO_4$	1°	—	-0.405	-0.433	-0.466	-0.486	-0.562
		20°	—	—	-0.390	-0.410	-0.428	-0.498
		50°	—	-0.324	-0.340	-0.363	-0.374	-0.427
		92°	—	—	—	-0.306	-0.315	-0.359

and also the effect of acidity and temp. With $N-CoCl_2$, the deposition potentials were:

	Neutral	0.5 per cent. H_3BO_3	2 per cent. H_3BO_3	0.003N-HCl	0.03N-HCl
E					
1°	-0.474	0.153	0.141	0.119	0.125
20°	-0.415	0.061	0.129	0.132	0.110
50°	-0.354	-0.004	0.012	0.072	0.070
75°	-0.317	-0.007	-0.001	0.043	0.054

Similar results were obtained with soln. of cobalt sulphate. The subject was also discussed by G. Devoto and A. Ratti, H. Stäger, F. Förster, E. Vogel, J. Heyrovsky, P. K. Frölich and G. L. Clark, S. Sartori, and G. Grube. R. Brdicka found that the deposition potential from soln. of cobaltous chloride becomes more positive as the concentration of the added calcium chloride increases. The ionic valency of cobalt in pink soln. is two-thirds, and in blue soln., it is 2. Cobalt deposits reversibly from blue soln., *i.e.* soln. containing about $10N$ - CaCl_2 at room temp., or, at 100° , $5N$ - CaCl_2 . The cathodic deposition potential of cobalt from blue soln. is about 0.3 volt more positive than it is from pink soln. with the same concentration of cobalt. The Co^{++} -ions are therefore more active in the blue soln. The irreversible deposition of cobalt from the pink soln. is attributed to the slow dehydration of the pink hydrated ions; and the reversible deposition from blue soln. is attributed to the ease of splitting the blue into dehydrated free Co^{++} -ions—*vide infra*, the deposition potential of nickel. S. Glasstone studied the simultaneous electro-deposition of zinc and cobalt. He found the electrodeposition potential and over-voltage in N -soln. to be respectively -0.56 and 0.25 volt at 15° ; -0.46 and 0.15 volt at 55° ; and -0.36 and 0.05 volt at 95° .

The **cathodic or hydrogen overvoltage**, or the minimum voltage for the first visible appearance of hydrogen with a cobalt electrode in N - H_2SO_4 , at 20° , was found by W. D. Harkins to be $E=0.22$ volt; with finely-divided cobalt, $0.5N$ - H_2SO_4 , at 20° ; M. Centnerszwer and M. Straumanis gave $E=0.29$ volt; and with cobalt deposited on platinum in $0.01N$ - H_2SO_4 , A. Thiel and W. Hammerschmidt gave $E=0.29$ volt, and on silver, $E=0.064$ volt. The galvanic polarization of cobalt was studied by E. Vogel; and the separation of hydrogen at the cobalt cathode by I. Slendyk and P. Herasymenko. N. Thon studied the subject. U. C. Tainton found that a high current density increases the hydrogen overvoltage with cobalt chloride soln. G. Carrara observed that at 19° to 20° , with smooth electrodes and N - H_2SO_4 in water, methyl alcohol, and ethyl alcohol, the respective hydrogen overvoltages were 0.25 , 0.20 , and 0.27 volt. N. Isgarischeff and H. Ravikovitch, and E. Newbery studied the **cathodic polarization**, and the latter observed that the electrode potential of cobalt in N - CoSO_4 is 0.22 volt; in N - $\text{Co}(\text{NO}_3)_2$, 0.21 volt; and N - CoCl_2 , 0.15 volt. The cathodic overvoltage of cobalt with current densities D milliamps. per sq. cm. in normal soln. is:

Current Density	2	6	10	20	50	100	200	400
CoSO_4	0.50	0.48	0.48	0.48	0.50	0.51	0.51	0.49
$\text{Co}(\text{NO}_3)_2$	0.26	0.38	0.45	0.57	0.73	0.72	0.69	0.64
CoCl_2	0.31	0.30	0.31	0.32	0.35	0.38	0.44	0.53
H_2SO_4	0.27	0.28	0.28	0.27	0.27	0.26	0.26	0.25
NaOH	0.25	0.28	0.28	0.29	0.29	0.29	0.30	0.30

The cathodic overvoltage resembles that of nickel but is more constant, being less liable to change with time or current density. In alkaline soln., at first the over-voltage is little higher than that of nickel, but gradually rises with time. At very high current densities, sudden rapid rises of overvoltage take place, sometimes directly the current density reaches a high value, and at others, after repeatedly raising and lowering the current density between the limits 2 and 2000 milliamperes per sq. cm. This rise may be as much as 0.4 volt, and after it has taken place the high overvoltage persists at all current densities, the metal then behaving like a new electrode, such as lead or zinc. Cleaning with glass-paper at once restores the normal overvoltage; hence the effect is purely a surface one and is probably due to the formation of a cobalt alloy.

J. Nicklès observed that if cobalt be superficially oxidized by heat, it assumes the **passive state** in fuming nitric acid; and St. Edme found that whilst cobalt always dissolves in the conc. acid without becoming passive, the cold, dil. acid does not attack the metal. E. Ramann attributed the passivity of cobalt to the formation of a protective film on the surface of the metal. W. W. Hollis said that

the passivation of cobalt by fuming nitric acid depends on the texture of the metal, the time of action, and the temp. The critical temp. above which the passive state disappears is about 10° . R. Schildbach observed that with soln. of cobalt chloride or sulphate, no passivation of cobalt was detected with current densities up to 182×10^{-4} amp. per sq. cm., and at temp. up to 92° . E. Newbery found that at 15° , and a current density of 0.4 amp. per sq. cm., cobalt does not become passive in *N*-soln. of cobalt chloride, nitrate, or sulphate; W. Hittorf observed the passivation of anodic cobalt in soln. of potassium dichromate, or sodium acetate; and H. G. Byers, in soln. of potassium carbonate or dichromate. E. S. Hedges observed that the presence of sulphuric acid or sodium sulphate hinders the passivation of cobalt in soln. of potassium dichromate; and cobalt is passivated in 0.5*N*- H_2SO_4 with a current density exceeding 0.16 amp. per sq. cm.; in 0.2*N*- Na_2SO_4 , by a current density exceeding 0.24 amp. per sq. cm., and in a 20 per cent. soln. of potassium cyanide, cobalt is immediately passivated. H. G. Byers found a current density of 0.84 amp. per sq. cm. is necessary to develop oxygen in *N*- NaNO_3 ; and one of 4 to 5 amp. per sq. cm. in *N*- NaHCO_3 and in *N*- KMnO_4 . W. Muthmann and F. Fraunberger, and C. Fredenhagen discussed the electrode potential of passive iron and cobalt, and they concluded that the anodic oxygen depresses the speed of the reaction with the metal and itself to such an extent that the anode is covered completely with a layer of oxygen, or that an alloy of metal and oxygen is formed which prevents further action, and so produces the passive state. H. G. Byers added that these negative potentials are due to the oxygen electrode and increase or decrease with the conc. of the oxygen; but they do not account for the passive state of iron in potassium cyanide and other reducing agents. G. Grube and O. Feucht found that passive cobalt is activated by cathodic polarization. E. Müller and F. Spitzer observed that in many cases the production of the passive state is accompanied by the formation of a film of oxide. The subject was studied by G. C. Schmidt, U. R. Evans, W. J. Müller, and E. Becker and H. Hilberg. According to E. Newbery, unlike nickel, cobalt cannot be passivated in dil. sulphuric acid with an electric current. Passivity, however, is readily produced in alkaline soln. W. Frese studied the effect of films on the photo-electric properties and on passivity; and A. S. Russell, the electronic structure of metals in the passive state. A. Smits and A. H. W. Aten observed that the potential of cobalt is raised by etching with hydrochloric, sulphuric, or nitric acids, and hence they attributed passivity to the existence of an allotropic modification of the metal in the surface layers—*vide* the passivity of iron. H. G. Byers, and E. S. Hedges, studied the periodic passivity of cobalt; U. Sborgi and A. Borgia examined the action of a magnetic field on passivity.

H. G. Byers and C. W. Thing showed that a cobalt anode becomes passive if the current density is sufficiently high. The passive state is indicated by an increased drop in the voltage, a decreased current, the evolution of oxygen, and the resistance of the metal to dissolution. The essential difference between cobalt and iron or nickel is that cobalt does not become passive at the low current densities required by nickel and iron. If cobalt assumes the passive state, it remains so even when the current density is reduced; and cobalt becomes active in acidic soln. more readily than is the case with nickel. H. G. Byers added that the anodic behaviour of cobalt containing some nickel is not very different from that of cobalt alone.

J. C. Poggendorff observed that the cell with a cobalt anode $\text{Co} : \text{KOH} : \text{HNO}_3 : \text{Pt}$ develops oxygen without forming a film oxide on the cobalt. According to C. Tubandt, cobalt is not attacked by a hot or cold soln. of potassium or sodium hydroxide, but when exposed as anode to an electric current, it dissolves in the alkali lye. The most favourable conditions for the dissolution are a low current density—0.2 amp. per sq. dm.—high temp., and a highly conc. soln. of lye. The cobalt dissolves as a cobaltous salt. The cobaltous soln. is blue, and in absence of air is stable for months. When electrolyzed between insoluble electrodes, it

precipitates part of the cobalt at the cathode as spongy metal, part at the anode as oxide; the chief part is oxidized by the oxygen given off at the anode, and the oxidation product remains suspended in the form of brown flecks in the electrolyte. F. Förster and A. Piquet observed that with 2*N*-KOH, at 15°, and a current density of 0.333 amp. per sq. cm., cobalt is attacked more strongly than iron, and a layer of hydrated cobaltic oxide may be formed on the metal. E. Newbery said that cobalt is passive in *N*-NaOH with a current density of 2 to 1200 milliamp. per sq. cm.; H. G. Byers, that in *N*-KOH and 5 milliamp., no loss in weight occurs; and F. Förster, that with 10*N*-KOH, and 0.3 milliamp. per sq. cm. at 60°, or 0.8 milliamp. per sq. cm. at 80°, a cobalt anode remains active, but with the same current densities respectively at 40° and 60°, passivity sets in as an oxide layer is formed. K. Georgi studied the anodic behaviour of cobalt.

G. Grube and O. Feucht found that with conc. soln. of potassium hydroxide, anodic cobalt dissolves at high current densities as deep-blue potassium cobaltite:

The potential measurements show that the blue compound in 8*N*-KOH is potassium cobaltite, K_2CoO_2 , and not colloidal cobaltous hydroxide. The normal potential of cobalt against potassium cobaltite is -0.52 volt. Fig. 16 shows that there are two stages in the potential current density curves; the first stage occurring with potentials between -0.3 and -0.6 volt. Here the cobalt is active; no oxygen is evolved at the anode; and with highly conc. alkali-lye, the blue soln. is formed, but with more dil. alkali-lye, an oxide is formed on the electrode or in the electrolyte. In the second stage, the cobalt no longer dissolves, and oxygen is developed.

FIG. 16.—The Current Density-Potential Curves of Cobalt in Potash-Lye.

The anodic oxidation of a soln. of the cobaltite, at platinum occurs in three stages: (i) at low potentials, cobaltous oxide is formed; (ii) at medium potentials, cobaltic oxide is produced; and at high potentials, a solid soln. of cobalt dioxide in one of the lower oxides is formed and the evolution of oxygen occurs. In the electrolytic evolution of oxygen at cobalt anodes in alkali hydroxide the cobalt first unites with the charged atomic oxygen forming cobalt dioxide, and this decomposes into cobaltic oxide and molecular oxygen. For G. Grube's observations on the polarization of cobalt in alkaline soln. of potassium ferrocyanide and ferricyanide, *vide* iron. A. P. Rollet discussed the anodic reactions of cobalt in acidic or alkaline soln.

U. Sborgi and G. Cappon found that cobalt dissolves in an ethyl alcohol soln. of calcium and ammonium nitrates as a bivalent ion at all current densities from 0.03 to 3.0 amp. per sq. dm.; and U. Sborgi and P. Marchetti found that cobalt forms bivalent ions in an acetone soln. of lithium chloride, and becomes passive in an acetone soln. of silver nitrate. N. Isgarischeff observed that the e.m.f. of cobalt in a 0.177*N*-soln. of cobalt chloride in ethyl alcohol, increases rapidly until the metal becomes passive; the potential remains unchanged at 0.03 volt against a H-electrode, and the smooth and white surface of the metal becomes matte with a yellow tinge. If the metal be removed and cleaned, it has its original potential when again immersed in the liquid, but the passive state is acquired more quickly than before, and on repeating the process, the rate at which the metal becomes passive continues to increase. If all the oxygen be removed from the soln., and observations made in a current of hydrogen, the potential remains constant, -0.174 volt, and there are no signs of passivation. The passivation in these organic solvents is thus attributed to the presence of a soluble substance of the nature of a peroxide, and the case of passivation of cobalt in alcoholic soln. is attributed to the formation of an oxide coating on the metal. N. Kondyreff observed that in a soln.

of ethyl bromide, in dry ether, cobalt does not dissolve anodically and no complex salt is formed. L. F. Audrieth and L. F. Yntema studied the electrodeposition of cobalt from solutions of the nitrate in liquid ammonia.

According to W. Hittorf, cobalt dissolves and is active when employed as anode in dil. soln. of sulphuric acid, sulphates, or nitrates; and in soln. of nitric acid of sp. gr. 1.2, H. G. Byers found a cobalt anode is dissolved in *N*-soln. of nitric, acetic, oxalic, and citric acid at room temp., and current density of $D=0.5$ amp. per sq. dm., and the dissolution of cobalt occurs at room temp. with the following values of D : *N*-NaCl, 0.5; *N*-CuCl₂, 1.0; *N*-KCl, 0.5; *N*-KNO₃, 1.0; 0.1*N*-KNO₃, 0.5; sat. soln. NaNO₂, 3.6; sat. soln. NaNO₃, 8.4; *N*-Na₂SO₄, 0.5; *N*-CoSO₄, 1.0; *N*-Na₂CO₃, 0.5; *N*-NaHCO₃, 0.5; *N*-K₂Cr₂O₇, 0.8; *N*-NaH₂PO₄, 0.5; *N*-KMnO₄, 0.4; and *N*-KClO₃, 0.5. Cobalt dissolves anodically in fuming nitric acid at 0°; and, according to E. Newbery, in *N*-HCl, while cobalt is not passive in *N*-H₂SO₄ at 15° and 2 amp. per sq. cm., at very high current densities, its potential approaches that of the oxygen electrode. E. S. Hedges said that cobalt is not passive in 0.05 to 20 per cent. hydrochloric acid; in 0.5 to 100 per cent. nitric acid; in 1 to 10 per cent. ammonium sulphate; or in 2 to 10 per cent. sodium sulphate. With small current densities, cobalt forms a red soln. with 50 vol. per cent. sulphuric acid, and a green soln. with high current densities. According to H. G. Byers and C. W. Thing, when cobalt is active and no current is flowing through the electrode, it has a negative potential, but when the electrode is an anode, and a current is flowing, the potential changes in sign, and increases in value even if the metal remains active. If the metal becomes passive, the potential is much increased. Thus, at 0°, against a normal calomel electrode:

		Potential		State of Metal
		without current	with current	
0.2 <i>N</i> -H ₂ SO ₄	{ Cobalt— 98 per cent. .	-0.350	+0.605 to 0.671	Active
	{ Cobalt— 98 „ .	-0.278	+1.888 to 1.849	Passive
	{ Cobalt— 98 „ .	-0.411	+0.270 to 0.250	Active
0.2 <i>N</i> -Na ₂ SO ₄	{ Cobalt— 98 „ .	-0.411	+1.811 to 1.824	Passive
	{ Cobalt—100 „ .	-0.416	+0.302 to 0.264	Active
	{ Cobalt—100 „ .	-0.416	+1.870 to 1.840	Passive
0.2 <i>N</i> -K ₂ Cr ₂ O ₇	Cobalt—100 „ .	-0.306	+2.422 to 2.522	Passive

According to A. Coehn and Y. Osaka, the **oxidation potential** of cobalt is 0.85 volt against a constant hydrogen electrode, and oxygen is evolved at 1.36 volts. A. Coehn and M. Gläser found that in a slightly alkaline soln., cobalt shows an anodic formation of oxide at 1.21 volts; in a slightly acidic soln., at 1.52 volts; and in a strongly acidic soln., no oxide is formed. The oxide deposited in thin layers is Co₂O₃.2H₂O, and in thick layers, Co₂O₃.3H₂O. Cobalt can be completely deposited as peroxide on the electrolysis of a dil. soln. with a current of 0.1 ampere, and 2.3 to 2.4 volts. A long time is required, and the method is not a convenient one for separating cobalt and nickel. E. Newbery observed the **oxygen or anodic overvoltage** of cobalt for current densities D milliamp. per sq. cm.:

Current Density	2	6	10	20	50	100	400	1200
NaOH	0.58	0.60	0.59	0.58	0.58	0.57	0.56	0.54
CoSO ₄	0.02	0.03	0.03	0.04	0.05	0.06	0.06	0.08
Co(NO ₃) ₂	0.11	0.11	0.09	0.06	0.00	0.00	0.02	0.02
CoCl ₂	0.03	0.02	0.00	-0.02	-0.03	-0.02	+0.03	+0.07

E. Newbery added that the anodic overvoltage is low and fairly constant, and has similar values in acidic and alkaline soln. It shows a tendency to fall slightly with time. F. Förster gave for the anodic potential of a cobalt electrode in *N*-KOH as the current density changes from 0 to 3×10^{-4} amp. per sq. cm., $E=0.7$ volt to about 0.92 volt. E. Müller and F. Spitzer said that at first the anodic potential rises gradually, and attains its end-value in about an hour with spongy cobalt, and in about 3 hrs. with polished cobalt. In 2*N*-NaOH, and a current density of 0.03 amp. per sq. cm., the end-value against a calomel electrode is 0.580 volt for

burnished cobalt, 0.476 volt for spongy cobalt, 0.477 volt for cobalt oxide, and 1.416 volt for platinum. The agreement between the values for cobalt oxide indicates that a layer of oxide is formed on the metal. The measurement of the anodic overvoltage was discussed by E. Newbery, A. D. Garrison and J. F. Lilly, and M. Knobel; the use of cobalt as an anode in electrolysis, by E. A. Benjamin, R. Saxon, J. H. Levin, and C. G. Fink. E. Müller and J. Janitzki observed that when the metal is rubbed, and immersed in soln. of acids, bases, or neutral salts, the electrode potential is nearly reversible. The use of the tungsten-cobalt couple for electrometric titrations was described by A. C. Krueger and L. Kahlenberg, and M. L. Holt and L. Kahlenberg; and the use of cobalt electrodes in reducing a soln. of barium nitrate to nitrite, by P. Wenger and A. Lubomirsky.

P. Bechtereff measured the anodic potential of cobalt in molten sodium hydroxide between 330° and 650°, and from its resemblance to the values for nickel, iron, and the noble metals, he concluded that a gas potential is actually measured. A. Günther-Schulze measured the **electrolytic valve action** of cobalt. A. P. Rollet found that in the electrolysis of dil. soln. of alkali lye, or dil. sulphuric acid, with an alternating current, the electrodes of cobalt are alternately covered with oxide, and powdered metal.

According to T. de Grotthus, when an electric current is passed through two soln. of silver nitrate communicating with each other by a crack in a glass tube containing one of them, and the positive pole is immersed in the external vessel, silver is deposited on the outside of the crack, and oxygen is given off inside. F. Braun showed that the phenomenon occurs with cobalt, iron, lead, gold, and palladium, but not with manganese or nickel salts, and the metal is deposited when the intensity of the current has attained a certain minimum value which depends on the conc. of the soln. This phenomenon—*electrostenolysis*—was studied by

FIG. 17.—The Thermoelectric Force of the Co-Pt Couple.

A. Schulze found that the thermoelectric force of the cobalt-platinum couple alters from 0° when $E_0=0$ to 100° when $E_{100}=-2.50$ millivolts. A minimum of -23.3 millivolts occurs at 960°. The temp. gradient, $dE/d\theta$, has a minimum at 350°, and a break between 465° and 470°. He observed:

	0°	100°	200°	350°	500°	600°	800°	1000°	1200°
E_θ	.0	-2.50	{ → - 5.54 ← - 5.58 → - 30.4 ← - 30.8	{ - 10.65 - 10.59 - 34.2 - 33.5	{ - 15.42 - 15.25 - 25.7 - 27.4	- 17.99	- 21.99	- 23.19	- 20.93
dE/dT		25.0				—	- 16.5	- 2.03	+ 14.6

The results in the vicinity of the temp. of magnetic transformation are plotted in Fig. 17, where E denotes the thermoelectric force in millivolts, and $dE/d\theta$, the temp. coeff. in millivolts per degree:

	1299°	1264°	1203°	1152°	1103°	1062°	1000.2°	904.3°	807.4°
E	-19.10	-19.73	-20.60	-21.27	-21.92	-22.46	-22.735	-22.64	-21.81
$dE/d\theta$		18.0	14.3	13.1	13.3	10.6	5.3	-0.96	-8.6

Observations were also made by W. Rohn, W. M. Latimer, and J. J. Schukoff. P. W. Bridgman gave -1.679×10^{-3} volt for the thermoelectric force of cobalt against platinum with the cold junction at 0° and the hot junction at 100° . H. Péchaux found for the *cobalt-copper* couple :

	0°	100°	200°	300°	400°	500°	600°	700°	800°	900°
E.m.f. .	0.00	-2.32	-5.2	-8.6	-12.1	-17.8	-19.4	-22.9	-25.9	-28.4

G. Reichardt represented his results between 50° and 200° by $E = 23.24\theta + 0.0413\theta^2$ microvolts ; for a hard-drawn wire between 20° and 60° , $E = 26.3$ microvolts, and after heating to dull redness, 25.8 microvolts. L. O. Grondahl and S. Karrer observed that with the cobalt-copper couple, the thermoelectric force decreases as the magnetic field increases in strength. P. McCorkle also observed a small increase as the value of dE/E in a longitudinal field, which attained a maximum at about 50 gauss, and the subsequent decrease attained a negative value at about 300 gauss. The effect of a small load was very small with strong magnetic fields. H. Péchaux, and C. Dannecker gave for the *cobalt-nickel* couple :—

	0°	100°	200°	300°	400°	500°	600°	700°	800°	900°
E.m.f. .	0.00	-0.3	-1.3	-2.6	-4.6	-6.9	-8.7	-9.8	-10.4	-10.1

With the cobalt-lead couple, the current goes from cobalt to lead through the hot junction, and G. Wietzel gave :

	24.1°	78.4°	108.2°	130.2°	169.9°	179.4°	207.6°	252.6°	257.8°
E .	-1.805	-1.860	-1.894	-1.888	-1.884	-1.440	-1.204	-1.491	-1.625

P. W. Bridgman gave for the cobalt-lead couple, e.m.f. = $-17.32\theta - 0.390\theta^2$ microvolts between 0° and 100° . He also found that the thermal e.m.f., E , microvolts or 10^{-6} volt, of a couple composed of one branch of uncompressed metal, and the other, compressed by a press. p kgrms. per sq. cm. when the junctions are at 0° and θ° :

p	10°	20°	40°	60°	80°	100°
2,000 .	-0.29	-0.59	-1.22	-1.91	-2.65	-3.48
6,000 .	-0.86	-1.76	-3.69	-5.75	-7.92	-10.21
12,000 .	-1.72	-3.52	-7.34	-11.47	-15.90	-20.61

R. von Dallwitz-Wegner gave for the *cobalt-constantan* couple, -0.0009 volt at 100° . W. H. Keesom and co-workers measured the thermoelectric force of the alloys against an alloy of gold and silver. O. L. Kowalke found for the thermocouples of *cobalt-nichrome*, the values indicated in (3), Fig. 18 ; for the *cobalt-advance* alloy (4), Fig. 18 ; for the *cobalt-constantan* (5), Fig. 18 ; for the *cobalt-iron* (2), Fig. 18 ; and for the *cobalt-nickel-iron alloy* (1), Fig. 18. J. Thiele studied the effect of the ageing of the metal on the thermoelectric force.

P. W. Bridgman found the **Peltier effect**, P , or the heat developed between compressed and uncompressed metal in joules per coulomb $\times 10^6$:

P	0°	20°	40°	60°	80°	100°
2,000 .	-7.6	-8.8	-10.3	-11.6	-13.8	-16.8
6,000 .	-22.7	-26.9	-31.3	-35.3	-39.5	-44.0
12,000 .	-45.9	-53.6	-62.2	-71.0	-80.3	-90.5

and for the cobalt-lead couple, $P = (17.32 - 0.078\theta)(\theta + 273) \times 10^{-6}$ volts. P. W. Bridgman also found the **Thomson effect**, σ , or the heat excess in compressed and uncompressed metal in joules per coulomb $\times 10^6$:

P	0°	20°	40°	60°	80°	100°
2,000 .	-2.2	-2.9	-4.4	-6.7	-9.2	-13.8
6,000 .	-13.9	-12.6	-11.6	-11.3	-10.9	-10.4
12,000 .	-20.5	-22.0	-23.5	-25.0	-26.4	-28.0

and for the cobalt-lead couple, $\sigma = -0.078(\theta + 273) \times 10^{-6}$ volts per degree. E. H. Hall, J. Monheim, and C. Benedicks discussed some theoretical phases of the subject.

E. H. Hall²⁶ found for the **Hall effect**—*vide* iron—with cobalt for $H=3463$ gauss, $R=2460 \times 10^{-6}$ at 18° ; for $H=9000$ gauss, $R=3550 \times 10^{-5}$ at 19° , and 4440×10^{-6} at 48° . A. von Ettinghausen and W. Nernst gave for $H=5650$ gauss, $R \times 10^6=1550$ at 18° . H. Zahn gave $R \times 10^6=1010$ at 18° , and for $H=4400$ gauss, $R \times 10^6=1610$ at 24° . F. Unwin gave $R \times 10^6=2450$ at 18° ; A. W. Smith, $R \times 10^6=2400$ at 24° for $H=17,000$ gauss; and H. B. Peacock gave $R \times 10^6=29,000$ at 18° . A. Kundt studied the relation between the Hall effect and the magnetic field—*vide* iron; and H. B. Peacock, and A. J. Sorensen, the Hall effect with thin films. The Hall effect was also discussed by H. Tomlinson, and G. Borelius.

The **Corbino effect**—*vide* iron—was found by O. M. Corbino, A. K. Chapman, and E. P. Adams and A. K. Chapman to be 5.86 for cobalt, and the Hall effect 4.61 when referred to copper unity, the magnetic field being $H=3560$. For the **Ettinghausen effect**, *vide* iron. H. Zahn gave $P \times 10^9=9$ at 18° , and 9 at 24° for $H=4400$; F. Unwin, 21.6 at 18° ; and E. H. Hall, 81.0 at 19° for $H=9000$ gauss; and 109.0 at 48° for $H=9000$ gauss. For the **Nernst effect**—*vide* iron—H. Zahn found that $Q \times 10^6=200$ at 18° ; F. Unwin, 780 at 18° ; A. von Ettinghausen and W. Nernst, 1540 at 18° when $H=5650$ gauss; E. H. Hall, 1900 at 25° and 2190 at 47° for $H=9000$ gauss; and A. W. Smith, 2000 at 60° for $H=17,000$ gauss. For the **Leduc effect**—*vide* iron—H. Zahn gave $S \times 10^9=130$ at 18° ; F. Unwin, 110 at 18° ; E. H. Hall, 377 at 25° and 429 at 47° for $H=9000$ gauss; and A. W. Smith, 640 at 53.7° for $H=11,800$ gauss. P. W. Bridgman discussed the relation between these thermomagnetic effects; J. Zahradnicel, the thermo-

FIG. 18. — Thermoelectric Force of Thermocouples of Cobalt and Some Base Metals.

magnetic longitudinal effect; K. Honda, and J. R. Ashworth, the relation between the ferromagnetic constants and other properties; O. von Auwers, K. Honda, L. W. McKeehan, and W. Steinhaus, the relation between the ferromagnetic constants and the atomic or molecular structure; G. Borelius, the electron theory; P. Weiss, P. Weiss and O. Bloch, O. Bloch, W. Heisenberg, E. Stoner, K. Baedeker, L. L. Campbell, A. Carelli, W. W. Stiefeler, J. Kunz, and A. Piccard, the magneton theory.

According to W. H. Wollaston,²⁷ cobalt is magnetic, so that its **magnetism** is to that of iron as 5 : 6 or 8 : 9; W. A. Lampadius said as 25 : 55. The subject was discussed by F. A. C. Gren, B. G. Sage, B. M. Tassaert, F. Kapf, R. Chevenix, T. J. Seebeck, J. J. Berzelius, J. C. Poggendorf, G. C. Haughton, C. B. Greiss, and B. Brodie. The metals here were not of a high degree of purity. M. Faraday said that the pure metal is not magnetic even at -80° , but later added that it is magnetic. H. A. Rowland, and H. T. Kalmus and C. Harper added that purified cobalt is magnetic at all temp. up to about 1150° , at which temp., W. Guertler and G. Tammann found it to become non-magnetic. H. E. J. G. du Bois and O. Liebknecht added that the magnetic behaviour of cobalt is more like iron than is the case with nickel. This subject was studied by J. Thomsen, E. Wedekind, and E. van Aubel. The magnetic properties of cobalt were investigated by W. F. Barrett, A. Kundt, H. E. J. G. du Bois, W. Lobach, E. Becquerel, H. Becquerel, Lord Kelvin (W. Thomson), E. Maurer, E. H. Hall, D. Goldhammer, G. Fae, A. von Ettinghausen, W. Nernst, C. G. Knott and co-workers, P. Bachmetjeff, J. Plücker, W. G. Hankel, A. Gaiße, J. Trowbridge and A. L. McRae, T. Spooner, G. Berson, J. C. Beattie, G. Potapenko, T. Kahan, L. Néel, and H. N. Warren.

According to J. A. Ewing, cobalt has a greater capacity for magnetization than nickel, and under the influence of a strong field, it takes up as much magnetism as cast iron. Its magnetic susceptibility is small when the magnetizing force is weak.

The influence of the magnetic field, H , on the intensity of magnetization, I , on 93 per cent. cobalt, cast and annealed, was found by H. Nagaoka and K. Honda to be :

Cast	$\left\{ \begin{array}{l} H \\ I \end{array} \right.$.	.	2.7	14.7	30.0	89.8	474	720
		.	.	3.0	274	467	778	1080	1136
Annealed	$\left\{ \begin{array}{l} H \\ I \end{array} \right.$.	.	3.6	22.4	77.5	281	461	788
		.	.	4	38	188	439	568	699

Measurements were also made by H. Becquerel, J. A. Trowbridge and A. L. McRae, P. McCorkle, C. Asmus, R. Gans, M. Samuel, K. Honda, W. W. Stiefler, J. A. Ewing and W. Low, and H. Masumoto. H. T. Kalmus and K. B. Blake found for 99.6 per cent. cobalt :

H	.	.	2.5	20.7	43.2	75.9	129.0	151.8
I	.	.	8.5	136.7	238.4	350.2	451.5	493.2

H. E. J. G. du Bois gave for moderately strong fields, at 100° :

H	.	.	200	400	600	800	1000	1200
I	.	.	856	988	1032	1056	1080	1090

and K. Honda gave :

H	.	45.4	144	294	481	715	976	1257
I	.	529	737	882	972	1048	1098	1163

H. Masumoto found for the intensity of magnetization of cobalt :

H	.	5.3	10.6	26.0	51.2	101.6	207	421	637
I	.	8.4	14.6	61.8	155	347	547	750	878

S. Kaya observed that with crystals of cobalt, I , the intensity of magnetization is a maximum at 26° , so that for $H=9000$ gauss, $I=1422$; for an impure 93.1 per cent. cobalt. H. E. J. G. du Bois gave for $H=8500$, $I_{\max.}=1200$; and J. A. Ewing and W. Low, gave for cobalt with 1.66 per cent. of iron, $H=15,000$, $I_{\max.}=1310$ —a little greater than is the case with cast iron. For cobalt with 1.66 per cent. of iron, the magnetization constants were :

Magnetic force, H	.	.	.	1,350	4,040	8,930	14,990
Induction, B	.	.	.	16,000	18,870	23,890	30,210
Intensity of magnetization, I	.	.	.	1,260	1,280	1,290	1,310
Permeability, μ	.	.	.	12.73	4.98	2.82	2.10

Under sufficiently strong magnetizing forces, less than 4000, the intensity of

FIG. 19.—The Permeability of Cast Cobalt.

FIG. 20.—Permeability of Strongly-Magnetized Cobalt.

magnetization, I , reaches a constant or nearly constant value. In stronger fields, the relation $B=16,300+H$ exists. The results are summarized in Fig. 19. O. Bloch found for a field of 10,000 gauss, the saturation values $B-H=4\pi I_\infty$:

$4\pi I_\infty$.	—273°	181°	409°	545°	781°	926°	1040°	1115°
	.	(170.20)	166.32	159.40	151.30	131.85	109.20	78.55	27.13

—vide the cobalt-nickel alloys, Fig. 20. H. T. Kalmus and K. B. Blake measured BH -curves for purified cobalt; R. Gans, and M. Samuel, the permeability. P. Weiss found that the law of approach of cobalt to the saturation value of the

intensity of magnetization, σ —i.e. the intensity of magnetization per gram—is $\sigma=162(1-1.11 \times 10^6 H^{-2})$, and at 17° , the saturation value $\sigma=162$. This was confirmed by A. Droz; whilst P. Weiss and H. K. Onnes obtained $\sigma=<163.6$ at the temp. of liquid hydrogen. W. W. Stiefler observed that the saturation value σ_∞ is a function of the temp., so that:

σ_∞	22°	235°	414°	608°	991°	1065°	1104°	1152°
	161.0	154.0	146.4	125.2	73.3	30.0	2.2	?

and further:

	22°			235°			414°		
H	725	3450	4270	625	3026	4386	460	3135	4515
σ	102.4	153.2	155.2	108.4	151.8	152.8	119.2	146.3	146.4
	874°			1065°			1104°		
H	215	2015	3915	1165	3060	4010	1400	2400	3050
σ	83.4	97.9	97.9	21.4	30.0	29.4	1.3	1.9	2.6

Measurements of the saturation were also made by R. I. Allen and F. W. Constant, P. Weiss, P. Weiss and R. Forrer, P. Weiss and H. K. Onnes, L. W. McKeehan, A. J. Sorensen, A. Droz, M. Samuel, F. Bloch, O. Bloch, A. Preuss, R. Sanger, and F. C. Powell. M. J. O. Strutt studied the magnetization of cobalt in fields of high frequency.

S. Kaya prepared large single crystals of cobalt and cut discs through the (0001)- and (1010)-planes respectively—Fig. 21. Magnetization was easy in the (1010)-plane in the direction

of (0001), but difficult in the direction (1010). The permeabilities in the two directions were respectively 380, and 4. The parallel and perpendicular components of the magnetization vary with a period of 180°

FIG. 21.—Magnetization of Single Crystals of Cobalt.

FIG. 22.—The Magnetization of Single Crystals of Cobalt.

in this plane. In the (0001)-plane, magnetization was difficult in the directions of both the principal axes (1010) and (1120). The saturation value for a single crystal rod, with its axes parallel to the direction of easy magnetization, (0001), was 1422 at 26° . It is suggested that the results are explained by the theory of K. Honda and Y. Okubo. K. Honda and H. Masumoto measured the magnetization of single crystals of cobalt, and some results are summarized in Fig. 22. The direction of the (0001)-axes is that of easy magnetization, and as the temp. is raised, the magnetization in weak fields increases up to 230° and then decreases. The saturation value for the magnetization of cobalt at absolute zero is estimated to be 1446 c.g.s. units. The directions of the (1010)- and (1120)-axes

are those of difficult magnetization. With a rise of temp. the magnetization increases up to 300° , and then remains almost constant. F. Bitter made some

observations with single crystals. F. C. Powell, and N. S. Akuloff studied the magnetic properties of single crystals of cobalt; and J. D. Hanawalt and L. R. Ingersoll, E. P. T. Tyndall and W. W. Wertzbaugher, L. C. Jackson, and A. J. Sorensen, the magnetic properties of thin films of cobalt; and H. E. Malmstrom observed no ageing effect. F. Bloch and G. Gentile, O. Dahl and J. Pfaffenberger, and N. S. Akuloff investigated the magnetic anisotropy of cobalt.

H. A. Rowland found a maximum susceptibility of 11.2. The rounded curves for cobalt resemble those for hardened iron. The residual magnetism is comparatively small, and the coercive force is 12. E. Maurer observed that cold-worked cobalt, annealed at different temp., gives a maximum induction B , and a maximum remanence, when annealed at 700°:

Annealed at . . .	20°	100°	300°	500°	650°	700°	750°	900°
Induction . . .	8,000	7,800	7,500	8,950	11,000	13,000	12,950	10,650
Remanence . . .	2,950	2,900	2,825	3,275	4,050	5,025	4,675	3,376
Coercive force . .	55.2	56.0	59.0	45.0	26.2	15.2	13.5	17.6

G. Berson measured the residual magnetism in cast cobalt, and found that, like the intensity of magnetization, with a constant field, it rises about 2.5 times as the temp. passes from 20° to 320°; and J. R. Ashworth calculated the ratio of the remanent magnetism at θ° to its value at -273° , to be:

	14°	20.9°	300°	390°	472°	560°	747°
Ratio	0.985	0.975	0.974	0.933	0.910	0.877	0.786

Observations were made by A. Perrier, and C. Asmus found that the maximum induction and remanence of cobalt increases with the magnitude of the step-by-step magnetization of the metal. The coercive force remains virtually unchanged. The coercive force of cobalt was measured by R. Gans. The results of M. Samuel are summarized in Fig. 23 for two different samples of cobalt. A. Kussmann

FIG. 23.—The Coercive Force of Cobalt at Different Temperatures.

FIG. 24.—The Cyclic Magnetization of Cobalt.

and B. Scharnoff discussed the relation between the coercive force and the mechanical hardness; and W. Luthe, and C. Asmus, the magnetic viscosity.

In the cyclic magnetization of a cast and turned cobalt rod with about 2 per cent. of iron, Fig. 24, J. A. Ewing observed a small initial magnetism; the greatest permeability, 174, occurred when the force was about 25, and this corresponded with a magnetic susceptibility of about 13.8. J. A. Fleming and co-workers observed that with 95.95 per cent. cobalt, the maximum values of the induction, B , field-strength, H , and the hysteresis loss, in ergs per sq. cm., were:

H	6.67	25.76	48.54	75.46	114.03
B	911	4110	5869	7052	8237
Hysteresis loss. . .	452	160	121	93	72

corresponding with: Hysteresis loss = $0.01B^{1.6}$ ergs per sq. cm. Observations were made by C. P. Steinmetz, W. Elenbaas, M. Samuel, W. W. Stiefler, R. Forrer and J. Martek, H. T. Kalmus and K. B. Blake, and H. E. J. G. du Bois. R. Beattie

observed a maximum hysteresis loss for an intensity of magnetization 700. K. Honda and S. Shimizu measured the hysteresis losses with cast cobalt, and the same metal annealed at 1100°, at ordinary temp., say 20°, and at -186°, and found :

	Cast Cobalt				Annealed Cobalt			
	20°		-186°		20°		-186°	
<i>H</i>	6.6	92.4	7.4	96.3	43.7	218.0	48.3	224.3
<i>B</i>	1,107	9,259	960	8,676	1,802	5,508	1,115	4,446

The Barchausen effect—*vide* iron—was studied by R. F. de Waard.

The effect of temperature on the magnetization of cobalt was studied by E. Becquerel, M. Faraday, G. Berson, R. Förer, and H. E. J. G. du Bois. The temp. coeff. of magnetization was found by J. R. Ashworth to be 0.0005 between 0° and 100°, and 0.00015 between 100° and 200°.

With annealed cobalt, K. Honda, K. Honda and S. Shimizu found that the variation of the magnetization curve with temp. has two maxima and two minima,

FIG. 25.—The Effect of Temperature on the Magnetization of Cobalt.

FIG. 26.—The Effect of Temperature on the Magnetic Induction of Cobalt.

Fig. 25. They found the intensity of magnetization, *I*, of cast cobalt, with different field-strengths, *H*, to be :

-186°	$\left\{ \begin{array}{l} H \\ I \end{array} \right.$	$\left\{ \begin{array}{l} 3.90 \\ 28 \end{array} \right.$	$\left\{ \begin{array}{l} 10.57 \\ 122 \end{array} \right.$	$\left\{ \begin{array}{l} 39.3 \\ 427 \end{array} \right.$	$\left\{ \begin{array}{l} 206.9 \\ 848 \end{array} \right.$	$\left\{ \begin{array}{l} 449 \\ 999 \end{array} \right.$	$\left\{ \begin{array}{l} 668 \\ 1063 \end{array} \right.$
20°	$\left\{ \begin{array}{l} H \\ I \end{array} \right.$	$\left\{ \begin{array}{l} 5.1 \\ 72 \end{array} \right.$	$\left\{ \begin{array}{l} 10.7 \\ 170 \end{array} \right.$	$\left\{ \begin{array}{l} 35.7 \\ 497 \end{array} \right.$	$\left\{ \begin{array}{l} 147.7 \\ 865 \end{array} \right.$	$\left\{ \begin{array}{l} 392 \\ 1027 \end{array} \right.$	$\left\{ \begin{array}{l} 610 \\ 1088 \end{array} \right.$

and similarly, for annealed cobalt :

-186°	$\left\{ \begin{array}{l} H \\ I \end{array} \right.$	$\left\{ \begin{array}{l} 7.80 \\ 9 \end{array} \right.$	$\left\{ \begin{array}{l} 39.0 \\ 64 \end{array} \right.$	$\left\{ \begin{array}{l} 80.0 \\ 148 \end{array} \right.$	$\left\{ \begin{array}{l} 167.4 \\ 282 \end{array} \right.$	$\left\{ \begin{array}{l} 347 \\ 426 \end{array} \right.$	$\left\{ \begin{array}{l} 702 \\ 589 \end{array} \right.$
31°	$\left\{ \begin{array}{l} H \\ I \end{array} \right.$	$\left\{ \begin{array}{l} 4.94 \\ 8 \end{array} \right.$	$\left\{ \begin{array}{l} 29.23 \\ 56 \end{array} \right.$	$\left\{ \begin{array}{l} 65.0 \\ 164 \end{array} \right.$	$\left\{ \begin{array}{l} 147.5 \\ 313 \end{array} \right.$	$\left\{ \begin{array}{l} 484 \\ 572 \end{array} \right.$	$\left\{ \begin{array}{l} 684 \\ 664 \end{array} \right.$
185°	$\left\{ \begin{array}{l} H \\ I \end{array} \right.$	$\left\{ \begin{array}{l} 13.45 \\ 49 \end{array} \right.$	$\left\{ \begin{array}{l} 19.52 \\ 96 \end{array} \right.$	$\left\{ \begin{array}{l} 63.5 \\ 325 \end{array} \right.$	$\left\{ \begin{array}{l} 94.3 \\ 411 \end{array} \right.$	$\left\{ \begin{array}{l} 279.2 \\ 677 \end{array} \right.$	$\left\{ \begin{array}{l} 376 \\ 758 \end{array} \right.$
619°	$\left\{ \begin{array}{l} H \\ I \end{array} \right.$	$\left\{ \begin{array}{l} 2.48 \\ 32 \end{array} \right.$	$\left\{ \begin{array}{l} 4.79 \\ 108 \end{array} \right.$	$\left\{ \begin{array}{l} 31.31 \\ 573 \end{array} \right.$	$\left\{ \begin{array}{l} 72.1 \\ 716 \end{array} \right.$	$\left\{ \begin{array}{l} 128.5 \\ 806 \end{array} \right.$	$\left\{ \begin{array}{l} 378 \\ 951 \end{array} \right.$
1060°	$\left\{ \begin{array}{l} H \\ I \end{array} \right.$	$\left\{ \begin{array}{l} 4.14 \\ 56 \end{array} \right.$	$\left\{ \begin{array}{l} 22.03 \\ 84 \end{array} \right.$	$\left\{ \begin{array}{l} 51.1 \\ 98 \end{array} \right.$	$\left\{ \begin{array}{l} 212.5 \\ 126 \end{array} \right.$	$\left\{ \begin{array}{l} 333 \\ 136 \end{array} \right.$	$\left\{ \begin{array}{l} 439 \\ 140 \end{array} \right.$

H. Wilde found that the variation in magnetization of cobalt in a weak magnetic field rises at first, gradually reaches a maximum at about 400°, and then decreases slowly, to vanish at the critical temp. This was confirmed by H. Nagaoka and S. Kusakabe, R. Ruer and co-workers, K. Honda and S. Shimizu, and H. Masumoto, who obtained the curves shown in Fig. 25, where in a field of 1000 gauss the magnetic induction increases gradually with rise of temp., and after passing through a maximum at 450°, decreases slowly. H. Wilde found that in strong fields, say

1000 gauss, the magnetization of cobalt decreases gradually from the beginning without showing any maximum—Fig. 26. If σ denotes the intensity of magnetization per gram, A. Preuss gave for $H=10,000$ gauss :

	17°	510°	693°	844°	971°	1090°	1133°	1144°	1149°
σ	165.5	149.2	136.9	120.5	99.37	62.53	32.09	20.64	17.89

Observations were also made by O. Bloch, H. Masumoto, W. W. Stiefler, and F. Tyler. O. Bloch gave for the magnetic susceptibility, χ :

	951°	984°	1027°	1084°	1146°	1151°	1245°
$\chi \times 10^6$	9.90	9.56	9.07	8.54	7.92	7.85	7.16

and P. Weiss and G. Foex :

	1156°	1170°	1188°	1208°	1241°	1242°	1261°	1280°	1302°
$\chi \times 10^{-6}$	785.3	560.2	384.4	283.1	197.3	196.1	162.7	139.8	119.1

Observations were also made by A. Preuss, and E. M. Terry.

P. Weiss and G. Foex said that Curie's law— $C=\chi(T-\theta)$, where C is Curie's constant, and θ the transformation temp. on the absolute scale—holds for β -iron- β -nickel, and β -cobalt at low temp., and that the points for the reciprocal susceptibility and temp. lie not on a straight line but rather on two straight lines which intersect at 1241°, and they accordingly speak of the β_1 - and β_2 -states. E. M. Terry could not confirm this. His data for cobalt are plotted in Fig. 27. When plotted on a larger scale, starting from the transformation point, 1100°, the curve for the reciprocal susceptibility has a gradual upward curvature throughout the entire region up to the m.p., 1485°; at this temp. there is a slight break in the susceptibility curve. These results do not agree with those of P. Weiss and G. Foex, and Curie constants for the metals cannot be deduced.

FIG. 27.—The Effect of Temperature on the Magnetic Susceptibility of Cobalt.

M. Faraday observed that the critical temp. of cobalt, that is, the temp. at which it loses its ferromagnetic properties, is near 1083°, the m.p. of copper, and analogous observations were also made by C. S. M. Pouillet, H. Wilde, and E. Becquerel. J. Pionchon added that some ferromagnetism is lost even at 300°, and almost all at about 900°; and H. Nagaoka and K. Honda observed that some is lost at 450°, and almost all at 1090°. The temp. of magnetic transformation, or the Curie point, that is, the temp. at which cobalt passes from the ferromagnetic to the paramagnetic state, was found by W. Guertler and G. Tammann to be 1150°, and later, they gave 1143° on a heating curve, and 1145° on a cooling curve; U. Raydt and G. Tammann gave 1143°; S. Umino, 1050°; R. Sahmen, 1115°; A. Schulze, 1128°; H. Nagaoka and S. Kusakabe, 1100°; K. Honda and S. Shimizu, 1090°; K. Honda, 1140°; K. Lewkonja, 1134°; W. W. Stiefler, 1075°; H. Masumoto, 1115°; P. Weiss, 1100°; O. Bloch, 1121° for $H=10,000$ gauss, and 1115° for $H=\sigma$; A. Göbl, 1112°; R. Ruer and K. Kaneko, 1112°; F. Wüst and co-workers, 950° to 1100°; and F. Wever and U. Haschimoto, 1115° to 1128°. The temp. of magnetic transformation corresponds with the A_2 -arrest of iron at 790°, and of nickel at 380°. J. J. Schukoff observed a small evolution of heat occurs on the cooling curve of cobalt at about 985°; and K. Honda noted that the phenomenon is much smaller with annealed cobalt than it is with the cast metal. F. Wüst and co-workers calculated for the sp. ht. a heat of transformation of 14.70 cal. per gram at 1025°, but other observers obtained higher values for the sp. ht. than did F. Wüst and co-workers. S. Umino obtained a heat absorption

of 2.0 cal. per gram with two kinds of cobalt at 1150°. The Curie point was studied by R. Ruer and K. Bode, and by R. Forrer—*vide* iron.

C. S. Yeh measured the effect of hydrostatic pressure on the magnetization of cobalt, and obtained the results plotted in Fig. 28. The values of dB/B_0 are expressed in percentages per 1000 kgrms. per sq. cm. :

H	.	.	.	10.9	21.8	32.8	45.2	56.1	72.4	79.5
B	.	.	.	380	981	1562	2130	2580	3165	3420
dB/B_0	.	.	.	-0.2	-0.2	+0.09	+0.27	+0.25	+0.38	+0.41

The press. coeff. of magnetization per unit vol. $\sigma B/B_0$ is expressed in per cent. per 1000 kgrms. per sq. cm.; it is negative for fields below 30 gauss, but positive for higher fields.

J. A. Ewing and W. Low measured the permeability of cobalt under no stress, and then under a series of loads producing compressive stress, and some results in Fig. 29 show the curves for no load, and for a load of 16.2 kgrms. per sq.

FIG. 28.—The Effect of Pressure on the Magnetization of Cobalt at 20°.

FIG. 29.—Induced and Residual Magnetism of Cobalt with and without Compressive Load.

mm. cross-section. Thus, under weak magnetic forces, the permeability of cobalt is increased by compressive stress, but when the magnetic force is large, the reverse is the case. C. Chree also obtained a reversal by pressure. The reversal also occurs with iron. H. Tomlinson studied the Villari critical temp. where traction produces no change in magnetic permeability; and J. W. Peck and R. A. Houston, the relations between stress and magnetization. The effect of press. was discussed by H. Nagaoka and K. Honda, P. McCorkle, and G. Wiedemann.

Lord Kelvin found that pulling decreased and relaxing the pull increased the induced magnetism of a cobalt bar hung vertically in the earth's magnetic field. C. Chree found that a reversal, resembling the Villari reversal of iron but opposite in character, occurs for longitudinal pressure, increases the magnetism in weak fields, but reduces it in strong fields. J. A. Ewing's curves, Fig. 29, illustrate the effect with a stress of 16.2 kgrms. per sq. mm. The crossing of the curves correspond with the reversal observed by C. Chree. There is also a reversal with the curves of residual magnetism with heavier loads. S. Bidwell found that the magnetic contraction of cobalt wires is not materially affected by tension.

W. F. Barrett observed that when cobalt is placed in a magnetic field, it increases in length, but C. Asmus found the decrease in length indicated in Fig. 30 to be produced by the magnetization of ordinary and annealed cobalt. The change is represented as a decrease in length in ten-millionths of the original length of the rod. The results obtained by K. Honda and S. Shimizu are indicated in Fig. 31, where the ordinate represents the change of magnetic expansion, and the abscissa, the temp. Each of the three curves for fields of $H=100, 400$, and 900 gauss, passes through the same point 460° , showing that cobalt undergoes a reversible magnetic

expansion above and below 460° for all field-strengths. H. Masumoto said that the rearrangement of the atoms affects the magnetization in a weak field but not

Fig. 30.—Deformation produced by the Magnetization of Cobalt.

Fig. 31.—The Effect of Temperature on the Expansion of Cobalt in Magnetic Fields of different Strengths.

in a very strong field where all the elementary magnets take the direction of the field. Consequently, the magnetization curves of cobalt before and after the transformation coincide in a strong field, so that the transformation appears only in the magnetization in a weak field, but vanishes in that of a strong field. S. Bidwell found that the changes in length with cobalt are almost but not quite independent of the presence of a longitudinal tensile stress. The subject was studied by A. Schulze. K. Honda and S. Shimizu's observations on the effect of temp. and magnetizing force on the magnetostriction of cast and annealed cobalt are summarized in Fig. 32. H. Masumoto gave for the magnetostriction of cobalt:

H	18.6	60.1	120.1	182	308	498	625
$\delta l/l \times 10^6$	-0.10	-0.34	-1.24	-2.34	-4.33	-7.13	-9.08

and K. Honda and K. Kido:

H	26.0	52.1	106.3	181.8	376.7	574.6
$\delta l/l \times 10^6$	-0.94	-2.61	-4.72	-6.68	-8.84	-10.41

Z. Nishiyama found that with single crystals in the direction of the axis of the hexagonal lattice, that is, of easy magnetization, there are small longitudinal and transverse contractions, Fig. 33. When the magnetic field is applied in a direction perpendicular to the axis, that is, in the direction where magnetization is difficult, the longitudinal effect is negative, and in the direction parallel to the base, the transverse effect is also negative, but positive in the direction of the axis. The magnitude of these effects is great when compared with the effect obtained when the magnetic field is applied in the direction of the hexagonal lattice. When the field is applied in the intermediate direction, the magnetostriction is rather larger than that in the principal directions. S. Kaya, S. R. Williams, H. Masumoto, A. Schulze, Y. Masiyama, W. Fricke, C. Asmus, H. A. Pigeon, R. Becker and M. Kornetzky, and P. McCorkle studied the subject.

Fig. 32.—The Effect of Temperature and Magnetizing Force on Magnetostriction of Cast and Annealed Cobalt.

Fig. 33.—The Changes in Length and Width by Magnetization.

G. Wiedemann discovered that when iron was suspended in a very small, vertical magnetic field, while at the same time an electric current flowed through the specimen, its free end was observed to twist in such a direction that to an observer looking along the specimen in the direction of the flow of current and also in the direction of the magnetic lines of force, the lines of twist were in the direction of a

FIG. 34.—The Magnetostriction in the Circular Magnetization of Cobalt.

circular magnetization of cobalt with currents from 0.308 to 6.677 amp. per sq. mm., by H. A. Pigeon, are summarized in Fig. 34, and the subject was discussed by K. Honda and S. Shimizu, H. A. Pigeon, and P. McCorkle. The gyromagnetic effect—*vide* iron—was studied by W. Sucksmith, D. M. Bose, D. M. Bose and H. G. Bhar, J. Dorfmann, and R. Jaanus and K. Honda; magnetization by rotation, by S. J. Barnett, S. J. and L. J. H. Barnett, and K. Honda; W. Köster and W. Schmidt, the lattice parameter and ferromagnetism; and the effect of a magnetic field on the viscosity, by E. Drago.

J. R. Ashworth studied the relation between the thermal and magnetic constants of cobalt. K. Honda and T. Tanaka observed that, unlike the case with iron, the elastic constants of cobalt are reduced by magnetization for all fields; they obtained for the effect of magnetization on the elastic modulus, E , and the coeff. of rigidity, K , the following values:

H	10.5	33.1	75.2	108	180	287	442
$\delta E/E \times 10^2$	0	-0.25	-0.45	-0.50	-0.50	-0.50	-0.55
H	22.5	55.0	111.0	160	257	325	402
$\delta K/K \times 10^2$	-0.045	-0.123	-0.160	-0.160	-0.180	-0.190	-0.200

P. Weiss and co-workers found the magnetic moment to be 8.67 for γ -cobalt, and 9.0 for cobalt alloyed with nickel; and P. Weiss and R. Forrer gave 9 and 17 for the atomic moment of α -cobalt. W. W. Stiefler calculated for the intrinsic molecular field, $H_m=8,870,000$; for the moment of the elementary magnet, $M=6.21 \times 10^{-20}$; for the number of atoms in an elementary magnet, $n=4$; and for the elementary charge, $e=4.65 \times 10^{-10}$ electrostatic units. The subject was discussed by C. Sadron, A. Chantillon, L. C. Jackson, A. Serres, P. Weiss and co-workers, S. Datta, K. R. More, E. C. Stoner, and H. Vatter. The position of cobalt in the theory of ferromagnetism was discussed by J. Dorfmann and R. Jaanus, A. Wolf, H. Fahlenbrach, R. Forrer, P. Collet, W. Heisenberg, E. C. Stoner, P. S. Epstein, I. Tamm, J. C. Slater, W. J. de Haas and E. C. Wiersma, H. Sachsse, G. Foëx, and F. Tyler—*vide* iron. E. H. Williams discussed the possibility that chemical bonds are formed by magnetic forces.

S. S. Bhatnagar and co-workers found that cobalt salts lose their paramagnetism and become diamagnetic when adsorbed on charcoal, and this is thought to favour the view that the adsorption is a case of chemical combination. The subject was

a right-handed screw, that is, the twist was positive in direction. The direction of twist was reversed upon the reversal of either the current or the longitudinal field. If the current in the specimen remained constant and the longitudinal field was gradually increased, the twist reached a maximum in fields of from 15 to 36 gauss, gradually decreased in stronger fields until in very strong fields the direction of twist changed and became negative or left-handed. This is commonly known as the *Wiedemann effect*. Observations on the effect with cobalt were made by C. G. Knott, and the results with the

discussed by D. M. Bose and co-workers. I. I. Rabi, J. H. van Vleck, R. W. Roberts, B. Cabrera, W. Klemm and co-workers, P. C. Ray and H. Bahr, R. Schlapp and W. G. Penney, L. A. Welo, R. Mercier, P. Collet, R. Gans and E. Czerlinsky, and L. Cambi and L. Szegő. H. A. Rowland and L. Bell studied the action of a magnetic field while cobalt is being attacked by chemical reagents; and D. M. Bose and P. K. Raha, the photo-magnetic effect with cobaltous salts.

§ 7. The Chemical Properties of Cobalt

W. Ramsay and J. N. Collie¹ found that helium has no chemical action on cobalt, at a red-heat; and when cobalt electrodes are spluttered in liquid argon, F. Fischer and F. Schröter observed no chemical action.

According to R. C. Böttger,² a thin strip of cobalt can adsorb hydrogen. G. P. Baxter found that cobalt in the form of ingots occludes very little hydrogen, but when reduced from its oxides, in hydrogen, so that the metal is in a fine state of subdivision, it occludes relatively large amounts of this gas. The vol. of occluded hydrogen varies, in the case of metal reduced from the oxide, with its purity and the temp. of reduction; it is remarkable that the metal reduced from cobalt bromide occludes practically no hydrogen; this appears to be due to its being deposited in a more compact form than that reduced from the oxide, as the presence of sodium bromide has no perceptible effect on the amount of occluded gas. Since the occlusion of hydrogen progresses very slowly at the ordinary temp. and is practically negligible at the temp. of reduction (400° to 500°), it must be a maximum at some intermediate temp.; the time during which the metal is in contact with hydrogen determines largely the amount of gas taken up. Although practically none of the hydrogen occluded is given off in vacuo at the ordinary temp., yet on heating in vacuo nearly the whole is evolved. L. J. Troost and P. Hautefeuille said that the metal reduced at 400° occludes about 100 times its vol. of hydrogen and this gas is given off on heating the metal in vacuo at 200°. G. Neumann and F. Streintz found that the metal can occlude 153 vols. of the gas, and if the experiment is repeated a number of times, 59-31 vols. are occluded. Observations were also made by T. W. Richards and co-workers, N. I. Nitikin, W. Hempel and H. Thiele, and H. Copaux. According to A. Sieverts and co-workers, the adsorption is measurable at 700°, and 760 mm.:

	700°	800°	900°	1000°
Hydrogen	0.17	0.25	0.34	0.52 c.c. occluded

M. M. Raessler observed that under similar conditions the hydrogen occluded by electrolytic cobalt is less than that by iron, and greater than that by nickel. It decreases with increasing thickness, and temp., but it increases with increasing

acidity of the electrolyte. H. S. Taylor and R. M. Burns found that between 25° and 218°, 1 vol. of cobalt absorbs less than 0.05 vol. of hydrogen. The hydrogen is given off at 400°, and the metal is readily oxidized. G. Neumann and F. Streintz observed that the repeated oxidation and reduction decreases the power of cobalt to occlude hydrogen, owing, said G. P. Baxter, to the increasing compactness of the metal. A. Sieverts represented the effect of pressure, p , on the solubility, S , of hydrogen in cobalt, by $S = k\sqrt{p}$, where k is a constant. N. I. Nitikin also made observations on this subject; and N. I. Nitikin, and D. Alexejeff and L. Savinina studied the diffusion of hydrogen in cobalt. The presence of impurities has no perceptible influence on the power of cobalt to occlude hydrogen. Observations were made by C. J. Smithells. B. Neumann also studied the absorption of hydrogen by cobalt salts; and R. Hocart, A. E. Mitchell and A. L. Marshall, A. Kailan and J. Kohberger, G. F. Hüttig and R. Kassler, R. Schenck and H. Klas, C. M. Loane, H. W. Underwood, H. Remy, W. P. Yant and C. O. Hawk, A. Kailan and O. Stüber, P. Sabatier, P. Sabatier and J. B. Senderens, and O. Schmidt, the catalytic action of cobalt in the hydrogenation of organic compounds, etc. T. Weichselfelder and B. Thiede found that when cobaltous chloride is treated with magnesium phenyl bromide in an atm. of hydrogen, **cobalt dihydride**, CoH_2 , is formed. F. Gläser reduced cobalt oxide in hydrogen and found that at 250°, the results corresponded with CoH_3 , and at 306°, with CoH_2 . H. Copaux also reported the formation of the hydride, but A. Sieverts did not accept the evidence. G. Hägg studied the mol. vol. of the hydride; and G. F. Hüttig and co-workers, their relations with other hydrides.

According to J. J. Berzelius,³ and H. V. Regnault, compact cobalt does not oxidize in **air** at ordinary temp., but it becomes superficially oxidized at a red-heat; and at an intense heat, the metal burns with a red-light. C. F. Schönbein added that the cold metal, which has been heated to the temp. of oxidation, contains a thin film of higher oxides. J. Jahn found that with cobalt at:

	Moist Air		Dry Air	
	199°	300°	198°	297°
Cobalt	3940.3	3939.4	2975.2	2971.1 mgrms.
Gain in weight	0	0.3	0	0.2

N. B. Pilling and R. E. Bedworth studied the oxidation of cobalt heated in air, and found the critical density ratio to be 2.10, whereas with copper the value was 1.70, and with iron, 2.07—*vide* iron. The subject was also discussed by G. Tammann and co-workers. H. P. Walmsley examined the nature of the smoke obtained by burning cobalt in air between electrodes of cobalt. G. Magnus observed that when reduced from the oxide at a low temp., cobalt is pyrophoric, and H. Hess added that the metal powder reduced at a red-heat, gradually forms the oxide on exposure to air. H. Moissan noted that the metal powder obtained by distilling the amalgam at 350° is not pyrophoric, but that the metal obtained by reducing the oxide in hydrogen at 250° is pyrophoric. The metal charged with occluded hydrogen was found by W. C. Henry to turn red-hot in a jet of **oxygen**. R. Schenck and H. Wesseldonk found that cobalt is activated towards oxygen by heating the finely-divided metal with oxides of those metals which form solid soln. or chemical compounds with cobalt oxide—*e.g.*, CaO , MgO , MnO , and Al_2O_3 . W. Biltz and W. Holverscheid found that the powdered metal can be preserved in a closed vessel, since on exposure it acquires a thin, protective film of oxide; but when very finely-divided, A. Krause observed that the metal is oxidized rather more quickly than nickel—*vide supra*, pyrophoric cobalt. H. W. Underwood studied cobalt as a catalyst in oxidation processes. Red-hot cobalt was found by H. V. Regnault, C. M. Despretz, and J. Thomsen to decompose **water** vapour; but, as shown by J. J. Berzelius, the metal is not attacked by water at ordinary temp. G. Chaudron found that in the reaction: $\text{Co} + \text{H}_2\text{O} \rightleftharpoons \text{CoO} + \text{H}_2$, the press. of water vapour at 800° is 10.9 mm.,

and of hydrogen, 0.3 mm.; at 1000°, 9.65 and 0.46 mm.; and at 1050°, 9.6 and 0.42 mm. W. Guertler and T. Liepus observed that cobalt is attacked during 8 hrs'. exposure to sea-water, sea-water plus air, and rain-water plus air. S. S. Bhatnagar and S. L. Bhatia studied the rate of evaporation of adsorbed water from cobalt; N. M. Zarubin, the rate of settling in water. H. Remy, and H. Remy and H. Gönning discussed the catalytic action of cobalt on detonating gas. W. Merckens observed that some hydrogen dioxide is formed when cobalt oxidizes in moist air. C. F. Schönbein noted that **hydrogen dioxide** is readily decomposed when in contact with cobalt, or cobalt salts, and the reaction was studied by A. Quartaroli, S. F. Cook, and A. C. Robertson.

H. Davy⁴ observed that heated cobalt takes fire in **chlorine**, and burns without incandescence; H. Rose added that finely-divided cobalt ignited in chlorine gas, forming blue, scaly crystals. W. Guertler and T. Liepus found that cobalt is attacked during 18 hrs'. exposure to chlorine water. J. B. Berthemot observed that when cobalt is heated to dull redness in the vapour of **bromine**, cobaltous bromide is formed. J. Nicklès said that the metal is scarcely attacked by a soln. of bromine in ether. O. L. Erdmann obtained the iodide by heating a mixture of finely-divided cobalt and **iodine**; and C. Winkler observed that cobalt iodide is formed by the action of a soln. of iodine and potassium iodide on cobalt. R. G. van Name and co-workers studied the rate of dissolution of cobalt in an aq. soln. of iodine and potassium iodide. G. Tammann discussed the formation of surface films by iodine vapour. H. E. Fierz-David found that, unlike iron, cobalt in association with iodine is not a satisfactory catalyst for the chlorination of benzene derivatives. A. D. White found that a soln. of **calcium hypochlorite**, of sp. gr. 1.04, gives off almost pure oxygen in contact with cobalt; and **hypochlorous acid** under similar conditions yields oxygen, chlorine and cobalt hydroxide and chloride. F. A. C. Gren observed that hot or cold **hydrofluoric acid** does not dissolve cobalt. Cobalt readily dissolves in **hydrochloric acid** with the evolution of hydrogen. J. Thomsen said the vigour of the reaction is between that of cadmium and tin. The order of the reaction with increasing vigour being Sn-Ni-Co-Cd-Fe-Zn. The action of the acid is augmented if the cobalt be platinized, or in contact with platinum. J. M. Weeren made similar observations with respect to the action of acids on cobalt, as were made in the case of zinc. W. A. Lampadius found that cold, fuming hydrochloric acid acts slowly on cobalt, forming a blue soln., and giving off hydrogen; the action is quicker with the hot acid, and an indigo-blue soln. is formed. W. Rohn observed that 99.5 per cent. cobalt, in contact with cold, 10 per cent. hydrochloric acid, lost 0.08 grm. per sq. dm. in 24 hrs., and 2.3 grms. per sq. dm. in 1 hour in the hot acid. W. Guertler and T. Liepus also found that cobalt is attacked during 8 hrs'. exposure to 10 or 36 per cent. hydrochloric acid. H. E. Patten found that cobalt is corroded by a soln. of hydrogen chloride in ethyl chloride, but not by a soln. in silicon tetrachloride, phosphorus trichloride, or antimony pentachloride. L. V. Pisarjehewsky, and M. A. Rozenberg and V. A. Yuza observed that a magnetic field retards the dissolution of cobalt in hydrochloric acid.

C. Frick,⁵ E. Schürmann, E. V. Britzke and A. F. Kapustinsky, and W. Guertler studied the affinity of **sulphur** for cobalt. J. L. Proust, and T. Hiortdahl observed that sulphur unites with red-hot cobalt to form a fusible sulphide. The effect of sulphur on the properties of the metal was studied by B. Bogitch. J. Jahn observed that when cobalt is exposed to **hydrogen sulphide** at:

	100°	151°	198°	248°	311°	413°
Cobalt . . .	2963.4	2974.8	2974.0	2975.1	2975.8	2977.3 mgrms.
Gain in weight . .	0.1	0.1	0.2	0.7	1.5	15.3 „

G. Tammann and W. Köster observed no change in the appearance of the metal after exposure to hydrogen sulphide and air at ordinary temp. H. Gruber observed

that the increase in weight of cobalt plates, $60 \times 13 \times 12$ mm., after 1 hour's exposure to hydrogen sulphide :

Increase in weight .	700°	800°	900°	1000°
	3.7	7.6	4.9	destroyed

H. E. Patten observed that cobalt is not acted on by **sulphur monochloride**, and E. H. Harvey observed no attack during 52 weeks' exposure; and N. Domanicki said that the attack is very slow, if any. P. Nicolardot did not detect any action below 136° ; and with a soln. of the monochloride in ether, the attack, if it occurs at all, is very slow. W. Guertler observed that cobalt is attacked during 8 hrs'. exposure to a 10 or a 50 per cent. soln. of **sodium sulphide**, or to a 4 per cent. soln. of sodium sulphide mixed with 8 per cent. of sodium hydroxide. E. Priwoznik observed that cobalt is very little attacked by a soln. of **ammonium sulphide**. E. Beutel and A. Kutzelnigg studied the surface films produced by heating the metal in contact with the **sulphides of copper, silver, mercury, and lead**. According to J. Uhl, when heated in a current of **sulphur dioxide**, cobalt is partially transformed into sulphide. J. Jahn observed that when cobalt is exposed to moist air and dry sulphur dioxide at :

	100°	149°	199°	250°	297°	417°	circa
Moist { Cobalt	748.2	748.2	739.2	1411.3	1411.5	3945.0	mgrms.
Moist { Gain in weight	0	0.2	0.3	0.3	0.3	2.2	„
Dry { Cobalt	2963.1	—	1411.8	—	3943.4	1412.1	„
Dry { Gain in weight	0.1	—	0.3	—	0.5	0.7	„

Observations were also made by J. Uhl. When cobalt is heated with **sulphurous acid** in a sealed tube, at 200° , cobalt sulphide and sulphur are formed; the reaction was studied by C. Geitner. C. Dufraisse and D. Nakae studied the catalytic oxidation of soln. of sodium sulphite. Cobalt is readily dissolved by **sulphuric acid** with the evolution of hydrogen—*vide supra*, hydrochloric acid. W. A. Lampadius observed that sulphuric acid of sp. gr. 1.700 does not attack the metal in the cold, and the action is slow with the hot acid. The acid is first coloured amethyst-blue, and when the liquid is evaporated, heptahydrated cobaltous sulphate is formed. W. Rohn observed that with cold, 10 per cent. sulphuric acid, and 99.5 per cent. cobalt, 0.06 grm. per sq. dm. is dissolved in 24 hrs., and with the hot acid, 0.30 grm. is dissolved in 1 hour. W. Guertler and T. Liepus observed that cobalt is attacked during 8 hrs'. exposure to 10 per cent. sulphuric acid, or to 20 per cent. sulphuric acid sat. with sodium sulphate. R. H. Adie observed that with hot sulphuric acid, sulphur dioxide, but no hydrogen sulphide, appears at 240° . W. R. E. Hodgkinson and N. E. B. Bellairs found that when cobalt is heated with **ammonium sulphate**, some sulphite is formed; and W. Smith, that ammonium hydrosulphate is produced. E. Beutel and A. Kutzelnigg studied the films produced by a boiling soln. of **sodium thiosulphate** and lead acetate. M. G. Levi and co-workers, and O. Aschan and G. V. Petrelius found that cobalt is dissolved by soln. of **potassium** or **ammonium persulphate** without the evolution of gas, and rather more slowly than is the case with nickel. J. J. Berzelius, and G. Little found that a heated mixture of cobalt and **selenium** combines with incandescence at a red-heat; and **tellurium** acts in an analogous manner. V. Lenher and C. H. Kao found that cobalt is not attacked by **selenium monochloride** at 100° ; W. L. Ray said that **selenium oxydichloride** acts very slowly; and V. Lenher, that **selenium oxydibromide** does not act on cobalt in a sealed tube at 100° .

A. Sieverts and co-workers⁶ observed that **nitrogen** does not react with cobalt at temp. up to 1150° , and that the vol. of nitrogen occluded at :

	15°	200°	500°	700°	800°	900°	1000°
Hydrogen .	1.09	1.27	1.21	1.41	1.49	1.58	1.76 c.c.

L. R. Ingersoll observed that a nitride is formed when cobalt is spluttered in nitrogen; and H. N. Warren, and G. Tammann measured the rate of formation

of the nitride. L. R. Ingersoll and J. D. Hanawalt measured the X-radiogram before and after the adsorption—*vide supra*. O. Meyer observed that cobalt is but slightly attacked by **titanium nitride** at 1600°. F. Vorster found that cobalt decomposes **ammonia** into nitrogen and hydrogen when it is heated in that gas. G. T. Beilby and G. G. Henderson also found that cobalt decomposes ammonia at 470°. P. Sabatier found that cobalt forms a nitride when heated in ammonia to 470°, and the nitride is decomposed at 600°. W. Traube and B. Löwe, and C. Matignon and G. Desplantes observed that reduced cobalt in air for 40 hrs. is oxidized in the presence of aq. ammonia, and a brown soln. is formed. W. R. E. Hodgkinson and N. E. B. Bellairs found that in the presence of air, cobalt dissolves in aq. ammonia with the gradual formation of a nitrite. W. Guertler and T. Liepus observed that 10, 50, and 70 per cent. aq. ammonia attacked cobalt in 8 hrs. The use of cobalt oxide as a catalyst in the oxidation of ammonia was studied by U. B. Bray. F. W. Bergstrom observed that cobalt shows no sign of attack when immersed in a soln. of **potassium amide** in liquid ammonia. W. R. E. Hodgkinson found that cobalt wire or foil is oxidized by molten **hydrazine hydrate**, reduced cobalt gives no explosion, but cobalt cubes produce an explosion. J. C. Roldan found that **hydroxylamine** in non-alkaline soln. acts on cobalt, producing an orange-red precipitate. P. Sabatier and J. B. Senderens found that reduced cobalt decomposes **nitrous oxide** incompletely at 230°, forming cobaltous or cobaltous oxide; it reacts at 150°, with **nitric oxide**; and at ordinary temp., **nitrogen peroxide** forms Co_3O_4 , and at 500°, Co_4O_5 —*nitro-cobalt*, $\text{Co}_2(\text{NO}_2)$, analogous to nitro-copper was obtained by P. Sabatier and J. B. Senderens, but the work of J. R. Park and J. R. Partington makes it doubtful if the nitro-cobalt is a chemical individual. F. Emich found that cobalt burns when heated in nitric oxide. P. Sabatier observed that **nitrosyl disulphonic acid**, $\text{NO}(\text{HSO}_3)_2$, converts cobalt into a cobaltic salt.

W. A. Lampadius observed that **nitric acid** of sp. gr. 1.30 attacks the metal in the cold, forming a dark red soln. of cobalt nitrate; and W. Hittorf noted that the action with an acid of sp. gr. 1.20 and less, is feeble. E. St. Edme found that cobalt becomes passive to nitric acid when it has been heated to redness in nitrogen gas. According to J. J. Acworth and H. E. Armstrong, conc. nitric acid attacks cobalt readily, but the 1:2-acid attacks the metal very slowly. W. Rohn found that cold, 10 per cent. nitric acid dissolves 10.7 grms. per sq. dm. in 24 hrs., whilst the hot acid dissolves 27.3 grms. per sq. dm. in 1 hr.—*vide supra*, the passive state. J. J. Acworth and H. E. Armstrong found that when the 1:2-acid attacks cobalt, the gas which is evolved—18.58 c.c. per gram at 18°—contains 5.71 per cent. NO; 79.23 per cent. N_2O ; and 15.06 per cent. N_2 . C. Montemartini found that a gram of cobalt in 27.5 per cent. nitric acid, yields 0.02538 gm. NH_3 ; 0.00077 gm. HNO_2 ; 0.00929 gm. N_2O ; and 0.00467 gm. N_2 . With 42.8 per cent. nitric acid, 0.01839 gm. ammonia was produced per gram of metal. It is said that the data do not agree with the assumption that the dissolution of the metal is accompanied by the formation of nascent hydrogen, or with the assumption that the metal is directly oxidized by the acid, rather does the nitric acid, in conjunction with the water present, act as an oxidizing agent. No hydroxylamine was observed in the final products of the reaction, so that if this compound is formed, it is again destroyed by secondary actions. The nitric oxide is of secondary origin, being formed by the decomposition of the nitrous acid. E. Ramann said that some cobaltous nitrate first formed by the action of nitric acid on cobalt, reacts: $4\text{Co}(\text{NO}_3)_2 + 8\text{H}_2\text{O} + 11\text{Co} = 4\text{NH}_4\text{NO}_3 + 5\text{Co}_3\text{O}_4$. W. Guertler and T. Liepus observed that cobalt is attacked during 8 hrs'. exposure to 10 and 50 per cent. nitric acid, and also to aqua regia. C. C. Palit and N. R. Dhar studied the rate of dissolution of cobalt in nitric acid; and A. Quartaroli observed that the presence of urea slows down the action of nitric acid; but H. J. Prins found an acceleration in the attack of cobalt by acids in the presence of benzaldehyde or nitrobenzene. F. A. C. Gren observed that **aqua**

regia dissolves cobalt in the cold, forming a soln. the colour of peach blossom. W. R. E. Hodgkinson and N. E. B. Bellairs found that when heated with molten **ammonium nitrate**, cobalt furnishes a little hydrogen and ammonia; and W. Smith observed that the molten nitrate attacks the metal. F. W. Bergstrom, and H. Ehrig studied the solubility in an ammoniacal solution of ammonium nitrate.

B. Pelletier⁷ found that **phosphorus** unites with red-hot cobalt to form a phosphide. S. F. Schemtschuschny and I. Schepeleff noted that a mixture of powdered cobalt and red phosphorus becomes warm at ordinary temp., presumably owing to the beginning of a reaction. A. Sieverts and M. Major found that cobalt reduced from the oxide, catalytically oxidizes soln. of **hypophosphites** with the evolution of hydrogen and the formation of some phosphoric acid. W. Rohn observed that 10 per cent. **phosphoric acid** dissolves 0.06 grm. of cobalt per sq. dm. in the cold in 24 hrs., and 0.7 grm. per sq. dm. in 1 hr. when heated. F. A. C. Gren said that cobalt is not attacked by a hot or cold soln. of phosphoric acid. A. Granger observed that the vapour of **phosphorus trifluoride** converts cobalt into phosphide; and likewise also **phosphorus tribromide**. A. F. Gehlen, C. J. B. Karsten, and T. Bergman observed that when **arsenic** is heated with cobalt, an arsenide is formed. A. F. Gehlen obtained an analogous result with **antimony** and cobalt; and K. Lewkonja, with **bismuth** and antimony. According to L. Kahlenberg and J. V. Steinle, at ordinary temp. **arsenic trichloride** slowly deposits a little arsenic on cobalt, and at 100° there is a slight reaction. F. A. C. Gren observed that **arsenic acid** dissolves a little cobalt.

M. Feszczenko-Czopowse⁸ studied the cementation of cobalt by **boron**. H. Moissan observed that boron unites with cobalt at a high temp., forming a boride; and F. A. C. Gren found that a **boric acid** soln., cold or hot, does not attack cobalt. C. Winkler, and H. Moissan found that at a high temp. a compound of **silicon** and cobalt is formed; B. Boren studied the lattice structure of the cobalt silicides; R. Vogel and K. Rosenthal, the equilibrium diagram—*vide* the silicides.

H. E. Patten observed that **silicon tetrachloride** has no action on cobalt. W. Wahl observed that purified, finely-divided cobalt attacks **porcelain** when first melted; commercial cobalt, possibly because of the presence of some oxide, when melted in a porcelain crucible, forms a deep blue, glassy slag. P. Schützenberger and A. Colson,⁹ G. Boecker, and O. Ruff and co-workers found that cobalt unites with **carbon**, and the reaction has been discussed in connection with carbides—5. 39, 20. F. Fischer and H. Bahr studied the carbide; and G. Tammann and K. Schönert, the diffusion of carbon in the metal. G. Boecker said that the saturation point for soln. of carbon in cobalt is 3.9 per cent. with a eutectic at 1300° and 2.9 per cent. of carbon. W. Nowacki studied the lattice structure of **cobalt tritacarbide**, Co_3C . O. Meyer observed that cobalt is attacked by **carbides**—silicon, molybdenum, and chromium at 1600°. I. L. Bell found that cobalt reacts less readily than nickel when it is heated with **carbon monoxide**, and a little carbon is formed: $2\text{CO} = \text{C} + \text{CO}_2$. P. Sabatier and J. B. Senderens said that the reaction occurs at 310°, and is almost complete at 420°, without the formation of a sublimate. The reaction was studied by R. Schenck and co-workers, and S. Kodama, and V. Kohlschütter and A. Nägeli observed that carbon is deposited at about 500°. E. F. Armstrong and T. P. Hilditch studied the reaction: $\text{CO} + 3\text{H}_2 = \text{CH}_4 + \text{H}_2\text{O}$, when activated by cobalt; C. M. Loane, the catalytic oxidation of carbon monoxide; and A. Erdely and A. W. Nash, the hydrogenation of water-gas. L. Mond and co-workers observed that, unlike nickel, cobalt does not form a carbonyl at atm. press., but at higher press., volatile cobalt tetracarbonyl is formed. H. S. Taylor and R. M. Burns found that 1 vol. of cobalt at 25°, 110°, and 218° absorbs respectively 1.05, 0.60, and 0.35 vol. of carbon monoxide. F. Fischer and H. Bahr, K. Fujimura, and H. A. Bahr and V. Jessen studied the reduction of the oxide by carbon monoxide and the fission of that gas by cobalt. Cobalt does not dissociate carbon monoxide at 225°. E. C. White and J. F. Schultz, J. C. W. Frazer, and H. Remy studied the action of cobalt as a catalyst in oxidizing carbon

monoxide, etc. I. L. Bell found that at a red-heat, **carbon dioxide** is reduced to the monoxide by cobalt. W. Guertler and T. Liepus observed that carbon dioxide and air attack cobalt in 8 hrs. R. Schenck and H. Wesseldonk found that cobalt has no appreciable action on carbon dioxide at 600°, and at 900° about 5 per cent. of carbon monoxide is formed. P. H. Emmett and J. F. Schultz studied the equilibrium in the reaction: $\text{Co} + \text{CO}_2 \rightleftharpoons \text{CoO} + \text{CO}$ at different temp. The constants, $K = [\text{CO}_2]/[\text{CO}]$, for the reactions at 450° and 570° are, respectively, 489.6 and 148.4. T. Bergman observed that an aq. soln. of carbon attacks cobalt slowly. Magnesia or manganese oxide accelerates the action, so that 40 per cent. of carbon monoxide is formed at 600°. Lime has no effect. N. I. Nitikin studied the adsorption of carbon dioxide by cobalt. E. P. Carpenter, J. R. Campbell and T. Gray, and W. P. Yant and C. O. Hawk studied the catalytic oxidation of **methane** by cobalt. F. Eisenstecken, and R. Schenck and co-workers studied the action of cobalt on methane. H. S. Taylor and R. M. Burns found that 1 vol. of cobalt at 25°, 110°, and 218°, absorbs respectively <0.50, 0.05, and <0.05 vol. of carbon dioxide; and respectively 0.35, 1.10, and <0.05 vol. of **ethylene**. R. N. Pease and L. Stewart, R. N. Pease and H. S. Taylor, and H. Hollings and R. H. Griffith studied the adsorption of hydrocarbons; and H. W. Walker, the reduction and polymerization of ethylene by cobalt at 400° to 450°; and O. Schmidt, the hydrogenation of hydrocarbons with cobalt as catalyst. H. Moissan and C. Moureu found that pyrophoric cobalt decomposes **acetylene** in the cold, and the metal becomes incandescent; some acetylene polymerizes to benzene, and some forms carbon and hydrogen. M. E. Kinsey and H. Adkins studied the catalytic decomposition of **acetaldehyde** by cobalt; F. Fischer and H. Koch, the catalytic synthesis of **benzene**; and J. H. Long, the hydrogenization of benzene. E. W. Kanning and O. W. Brown, the catalytic decomposition of **kerosene** by cobalt. H. E. Patten found that cobalt was tarnished by **ethyl chloride**. G. F. Hüttig and R. Kassler found that in the decomposition of **formic acid** with cobalt prepared in different ways as catalyst, the catalytic activity is conditioned by the temp. of reduction of the oxide. The difference is negligible with temp. between 300° and 550°; but if the reduction temp. is 1000° to 1200°, the activity of the metal is considerably diminished. The metal produced by reducing the hydroxide was rather more active than when obtained by calcining the nitrate. W. Rohn observed that 10 per cent. **acetic acid** dissolves 0.04 gm. per sq. dm. in 24 hrs. in the cold, and 0.15 gm. per sq. dm. in 1 hr. when heated. F. A. C. Gren observed that cobalt is not dissolved by cold or hot acetic acid, but C. Schall and H. Markgraf found that 4 hrs' action at ordinary temp. dissolves about 0.0021 gm. of cobalt (per 6.5 sq. cm.). F. A. C. Gren observed that **oxalic acid** dissolves cobalt in the cold. W. Guertler and T. Liepus found cobalt is attacked after 8 hrs' exposure to acetic acid, **citric acid**, and **tartaric acid**. G. Dupont and J. Allard studied the autoxidation of **abiatic acid** in the presence of cobalt. C. B. Gates said that cobalt is not attacked by **oleic acid** between 90° and 100°. A. Brochet and J. Petit studied the dissolution of a cobalt anode in a soln. of **potassium cyanide** under the influence of an alternating current. C. Kelber observed that finely-divided cobalt can be used like nickel (*q.v.*) as a catalyst in the hydrogenation of many compounds, but the reaction proceeds rather more slowly. C. Dufraisse and D. Nakae studied the catalytic oxidation of acetaldehyde, phenylaldehyde, furfuraldehyde, styrene, and turpentine. A. Benedicenti and co-workers, and G. B. Bonino and co-workers found that powdered cobalt unites with the **proteins** when shaken with a soln. of egg-albumin or blood-serum. L. L. Steele studied the effect of cobalt soap on the drying of **linseed oil**; and W. Thomson and F. Lewis observed no effect on **india-rubber**. A. Simon and K. Kötschau observed that finely-divided cobalt with benzidine and **guaiacum resin** gives a blue coloration, indicating the formation of hydrogen dioxide.

K. A. Hofmann and H. Hiendlmaier¹⁰ found that cobalt is readily attacked by burning **potassium**. W. G. Imhoff studied the corrosive action of molten **zinc**

on cobalt. According to C. Tubandt, cobalt is not attacked by **potassium or sodium hydroxide**, hot or cold, but if the metal be the anode to an electric current, it dissolves in the alkaline liquid. The most favourable conditions for the dissolution are a low current density—0.2 amp. per sq. dm.—a high temp., and a highly conc. soln. The cobalt dissolves as a cobaltous salt. For the anodic dissolution of cobalt in 8*N*-KOH, resulting, according to G. Grube and O. Feucht, in the formation of a dark blue soln. of potassium cobaltite, *vide supra*, the anodic behaviour of cobalt. M. le Blanc and O. Weyl observed that when cobalt is fused with potassium hydroxide in an atm. of nitrogen at 550° to 560°, there is a perceptible reaction although no water, hydrogen, or potassium has been detected in the product. C. Winkler observed that if the cobalt has been prepared by reduction at a low temp. from the precipitated oxide, hot potash-lye forms a dark blue soln. W. Guertler and T. Liepus observed that in 8 hrs. cobalt is attacked by 10 and 50 per cent. soln. of sodium hydroxide, and by a mixture of soda-lye and hydrogen dioxide. H. Moissan found that in the electric arc-furnace cobalt is oxidized by molten **calcium oxide**. C. B. Gates observed that cobalt does not react with molten **calcium chloride**. W. Guertler and T. Liepus found that cobalt is attacked during 8 hrs'. exposure to a soln. of **magnesium chloride**. E. Ramann observed that powdered cobalt acts on **cobaltous nitrate**, giving a dark-coloured precipitate; and when warmed, ammonia is evolved and the precipitate becomes pale red. J. B. Senderens observed that when a soln. of **copper, silver or lead nitrate** is treated with cobalt, the amount of cobalt passing into soln. is greater than corresponds with the equation: $M(NO_3)_2 + Co = Co(NO_3)_2 + M$. The excess is slight with silver, and is negligible if air be excluded. In the other cases, the metal oxidizes at the expense of the nitric acid present, forming a hydroxide or basic nitrate. W. Eidmann observed that a soln. of **cupric chloride** in acetone acts slowly on cobalt, forming cuprous and cobaltous chlorides. C. B. Gates found that copper is precipitated from fused **copper palmitate** by cobalt; a little copper is precipitated from **copper stearate**; and none from **copper margarate**. C. B. Gates observed that cobalt reacts with molten **silver nitrate or chloride** with the separation of silver. C. Winkler, and G. Krüss and F. W. Schmidt found that cobalt acts on a neutral soln. of **gold chloride**, precipitating yellowish-brown gold free from cobalt, but if alkalies are present, cobaltiferous gold is precipitated. W. Guertler and T. Liepus found that a 1:500-soln. of **mercuric chloride** is decomposed by cobalt. E. Alexander observed that a soln. of mercuric chloride in ethyl acetate does not attack cobalt. J. Napier found that cobalt reduces soln. of **ferric chloride** to the metal. T. Heymann and K. Jellinek studied the equilibrium conditions in the reaction: $Co + Ni^{++} \rightleftharpoons Ni + Co^{++}$ with soln. of **nickel nitrate and sulphate**. M. Curie and J. Saddy studied the inhibition of the luminescence of the **zinc sulphide** phosphor by the presence of cobalt.

Some reactions of analytical interest.—Soln. of cobaltous salts give no precipitate with **hydrogen sulphide** if free acids are present; and if the soln. is neutral, a part of the cobalt is slowly precipitated as a hydrated cobaltous sulphide. A soln. of cobaltous acetate in the presence of acetic acid gives either no precipitate or only a very small one, but in the absence of free acid, the precipitation is complete or almost complete. If the soln. contains an excess of alkali acetate, and free acetic acid is absent, all the cobalt may be precipitated by hydrogen sulphide from hot soln. Free tartaric, citric, monochloroacetic, or formic acid also hinder the precipitation, but the alkali salts of these acids enable the precipitation to be made from hot soln. This subject was discussed by H. Baubigny,¹¹ H. Delffs, A. Terreil, A. Villiers, L. L. de Koninck, F. Field, and O. F. Tower. Hydrogen sulphide in alkaline soln., or a soln. of **alkali or ammonium sulphide or hydrosulphide** gives a black precipitate of hydrated cobaltous sulphide. The precipitation is favoured by ammonium sulphide. The precipitate is insoluble in alkali and ammonium sulphides, it is very slightly soluble in acetic acid, and it dissolves with difficulty in hydrochloric acid, and particularly so if the precipitation has been

made from hot soln. Hot nitric acid and aqua regia dissolve the precipitate. This subject was discussed by A. Terreil, H. W. F. Wackenroder, F. Field, and G. Chesneau. According to F. Jackson, the reaction with ammonium sulphide is sensitive to 1 : 512,000, and, according to C. H. Pfaff, 1 : 200,000. C. D. Braun found that **potassium thiocarbonate** colours ammoniacal, conc. soln. of cobaltous salts brown or black, and dil. soln. yellow. P. Berthier found **potassium sulphite**, but not **ammonium sulphite**, gives an incomplete precipitation of a basic sulphite. P. Falciola, and W. Heinz observed red colorations with ammoniacal soln. of cobalt salts and **sodium hydrosulphite**. O. Brunck observed that **sodium hyposulphite** precipitates cobalt sulphide from neutral, ammoniacal, or acetic acid soln., but not in the presence of mineral acids. H. Marshall found **persulphates** precipitate cobaltic oxide. Acidic soln. give no precipitate with **sodium thiosulphate**, and with neutral soln., an incomplete precipitation of cobaltous sulphide occurs after a prolonged boiling. The reaction was studied by O. W. Gibbs, F. Faktor, W. Ball, and A. Terreil.

Cobaltous salt soln. give a blue precipitate of a basic salt: $\text{CoCl}_2 + \text{KOH} = \text{KCl} + \text{CoCl}(\text{OH})$, when treated in the cold with **potassium or sodium hydroxide**, but on warming, pink cobaltous hydroxide is precipitated. With moderately conc. soln., the pink precipitate may be produced in the cold, or after the soln. has stood some time. The rate of precipitation is dependent on the conc. of the alkali-lye. F. Jackson said that the reaction with sodium hydroxide is sensitive to 1 : 16,000. Cobaltous hydroxide, unlike the corresponding nickel hydroxide, gradually turns brown on exposure to air, owing to oxidation: $2\text{Co}(\text{OH})_2 + \text{H}_2\text{O} + \text{O} = 2\text{Co}(\text{OH})_3$. If alcohol and alkali-lye be added to the soln. of a cobaltous salt, and the mixture is boiled, dark brown cobaltic hydroxide is quickly formed. The presence of ammonium chloride hinders the precipitation by alkali hydroxide. The precipitated hydroxide or basic salt dissolves completely in a soln. of ammonium carbonate to form a violet-red soln. This subject was studied by A. Remelé, F. Reichel, E. Donath, H. Ditz, C. Winkler, and G. C. Winkelblech. Cobaltous hydroxide is peptized or dissolved by a very conc. soln. of alkali hydroxide, forming a blue liquid. This was examined by E. Donath, and C. Tubandt. H. Demarçay observed that **magnesium oxide** gives a precipitate with warm cobalt salt soln. In the absence of ammonium salts, aq. **ammonia** precipitates a blue basic salt from soln. of cobaltous salts, and the precipitate is soluble in soln. of ammonium chloride. Citric and tartaric acids hinder the precipitation. The dirty yellow, ammoniacal soln. gradually turns a reddish colour on exposure to air. The reaction was studied by F. Field, and H. Ditz. A reddish basic salt, of varying composition, is precipitated from cobaltous salt soln. by **alkali carbonates**; and the reddish, basic salt precipitated by **ammonium carbonate** is soluble in excess. The subject was studied by F. Field. According to J. N. von Fuchs, and G. C. Winkelblech, cobalt salts are not precipitated when they are heated with calcium carbonate, or boiled with strontium carbonate; H. Demarçay found that the **alkaline earth carbonates** and magnesium carbonate do not precipitate cobalt salts in the cold, but they do so above 75°. J. W. Döbereiner also noted the precipitation with **magnesium carbonate**. Barium carbonate and bromine give a black precipitate of cobaltic oxide, with cobaltous salts, but not so with nickel salts.

When **oxidizing agents**—chlorine, bromine, hypochlorites, hypobromites, hypiodites, barium dioxide, hydrogen dioxide, etc.—are added to an alkaline soln. of a cobalt salt, cobaltic hydroxide is immediately precipitated: $\text{Co}(\text{OH})_2 + \text{NaOH} + \text{Cl} = \text{NaCl} + \text{Co}(\text{OH})_3$. These reactions were studied by O. Popp, A. Terreil, F. Field, C. D. Braun, E. and B. Klimenko, E. P. Alvarez, W. Kwasnick, C. Reichard, R. G. Durrant, C. C. Palit, A. Job, A. Jaworowsky, T. Poleck, G. Kassner, O. W. Gibbs, F. Gauhe, H. Rose, and R. L. L. Taylor. The precipitation with **potassium iodate** was studied by S. R. Benedict, and S. E. Moody.

When conc. soln. of cobalt salts, acidified with acetic acid, are treated with **potassium nitrite**, a yellow crystalline precipitate is formed; with dil. soln., the

precipitation occurs only after the mixture has stood for some time. The reaction is supposed to take place in stages—first the formation of nitrous acid: $\text{CoCl}_2 + 2\text{KNO}_2 \rightleftharpoons \text{Co}(\text{NO}_2)_2 + 2\text{KCl}$, and $2\text{KNO}_2 + 2\text{CH}_3\text{COOH} = 2\text{CH}_3\text{COOK} + 2\text{HNO}_2$; the oxidation of cobaltous nitrite to cobaltic nitrite: $\text{Co}(\text{NO}_2)_2 + 2\text{HNO}_2 = \text{H}_2\text{O} + \text{NO} + \text{Co}(\text{NO}_2)_3$; and finally, the formation of the complex salt: $\text{Co}(\text{NO}_2)_3 + 3\text{KNO}_2 = \text{K}_3\text{Co}(\text{NO}_2)_6$. This reaction is used for the detection of cobalt salts in the presence of nickel salts, and it was studied by N. W. Fischer, S. Evre, O. L. Erdmann, A. Duflos and N. W. Fischer, S. Tanatar and S. Petroff, H. Yagoda and H. M. Partridge, C. D. Braun, etc.—*vide supra*, the separation of cobalt and nickel.

Neutral soln. of cobalt salts give with **potassium cyanide** a reddish-brown precipitate which is soluble in excess in the cold, forming a brown soln. of potassium cobaltocyanide, $\text{CoCl}_2 + 2\text{KCy} = 2\text{KCl} + \text{CoCy}_2$, and $\text{CoCy}_2 + 4\text{KCy} = \text{K}_4\text{CoCy}_6$. When the brown soln. is warmed for some time, it becomes yellow, and alkaline, owing to the formation of cobalticyanide: $2\text{K}_4\text{CoCy}_6 + \text{H}_2\text{O} + \text{O} = 2\text{KOH} + 2\text{K}_3\text{CoCy}_6$. The oxidation proceeds more quickly in the presence of oxidizing agents—*e.g.* chlorine, hypochlorites, etc. An excess of the oxidizing agent decomposes the nickel but not the cobaltic salt. The cobaltocyanide is decomposed by hydrochloric acid, but not so the cobalticyanide. The cobalticyanide forms sparingly soluble salts with most of the heavy metals—*e.g.*, cobaltous (pink) and nickel (green) cobalticyanides are formed. If a mixed soln. of cobalt and nickel salts be treated with an excess of potassium cyanide, and the boiling soln. be treated with hydrochloric acid, green nickel cobalticyanide is precipitated: $2\text{K}_3\text{CoCy}_6 + 3\text{K}_2\text{NiCy}_4 + 12\text{HCl} = 12\text{KCl} + 12\text{HCy} + \text{Ni}_3(\text{CoCy}_6)_2$. The reaction was studied by J. von Liebig, F. Wöhler, J. Tattersall, G. Papasogli, C. Krauss, E. P. Alvarez, O. W. Gibbs, F. Gauhe, etc.—*vide supra*, the separation of cobalt and nickel. A. Remelé showed that **potassium ferrocyanide** gives a dark greyish-green precipitate with cobaltous salts, and when the mixture is boiled in air, it becomes dark blue; the brownish-red precipitate with **potassium ferricyanide** under similar conditions becomes dark green. The reaction was studied by W. Skey, R. H. Davies, A. H. Allen, L. Mindaljeff, F. F. Werner, and W. F. Gintl. R. Ripan, and B. J. F. Dorrington and A. M. Ward found that **potassium cyanate** gives a blue coloration. If a conc. soln. of **ammonium thiocyanate** be added to a soln. of a cobaltous salt, the colour changes to bright blue: $\text{CoCl}_2 + 2\text{NH}_4\text{CyS} = 2\text{NH}_4\text{Cl} + \text{Co}(\text{CyS})_2$, and $\text{Co}(\text{CyS})_2 + 2\text{NH}_4\text{CyS} \rightleftharpoons (\text{NH}_4)_2\text{Co}(\text{CyS})_4$. If water be added, the colour changes to pink; but if shaken with amyl alcohol and ether, the blue salt passes into the ethereal layer. The reaction was studied by H. W. Bettink, H. Ditz, F. W. Dootson, F. Feigl and R. Stern, M. Gorsky, R. Grassini, I. M. Kolthoff, T. T. Morell, A. D. Powell, A. Rosenheim and co-workers, N. Rusting, L. Schönn, G. Sensi and R. Testori, A. Simon, N. A. Tananaeff, F. P. Treadwell, H. W. Vogel, C. H. Wolff, and C. Zimmermann. The colour is sensitive to nearly 1 : 20,000. J. J. Fox precipitated cobalt quantitatively with **potassium selenocyanide**.

H. Weil observed that neutral soln. of cobalt salts with **potassium chromate** give a brownish-red precipitate of a basic chromate; A. Carnot obtained no precipitation with **ammonium molybdate**, or with **ammonium tungstate**. A. Liebersson obtained a blue coloration with **arsenatophosphotungstic acid** in the presence of a cyanide. P. Berthier obtained a blue precipitate with **sodium hydrophosphate**. C. D. Braun obtained a precipitate with **sodium pyrophosphate** in the presence of a hypochlorite. S. J. Jindal observed that **sodium silicate** gives a blue precipitate. Soln. of cobalt salts give a turbidity with **oxalic acid**, and C. H. Pfaff found that with **alkali oxalates**, the reaction is sensitive to 1 : 1000.

M. Ilinsky and G. von Knorre found that **α -nitroso- β -naphthol** gives a red precipitate with acetic acid soln. of cobalt salts. The reaction was studied by C. Krauss, C. Meineke, R. Fischer, F. W. Attack, L. L. de Koninck, H. Copaux, and W. H. Chapin—*vide supra*, the separation of nickel and cobalt. I. Bellucci said that **β -nitroso- α -naphthol** is more sensitive for cobalt than **α -nitroso- β -naphthol**.

O. Brunck observed that **α -dimethylglyoxime** gives a precipitate with nickel but not cobalt salts in a strongly ammoniacal soln.—*vide supra*, the separation of nickel and cobalt—and it was studied by L. Tschugaeff, K. Kraut, F. Feigl and L. von Tustanowska, and G. Sensi and R. Testori. H. Grossmann and W. Heilborn found that **dicyanodiamidine sulphate** gives a precipitate of the nickel but not the cobalt salt in strongly ammoniacal soln.—*vide supra*, the separation of nickel and cobalt. G. Malatesta and E. di Nola found that cobalt, copper, and nickel salts give a blue coloration in ammoniacal soln. when treated with **1 : 2-diaminoanthraquinone-3-sulphonic acid**; W. R. Orndorff and M. L. Nichols, and M. L. Nichols and S. R. Cooper, a reddish- or bluish-violet coloration with **dinitrosoresorcinol**; C. Brenner obtained a blue coloration by **nitrosochromotropic acid**; H. S. van Klooster, a red coloration with sodium acetate and a soln. of a **nitroso-R-salt**; F. Kröhnke, a reddish-yellow coloration or precipitate with **isonitrosoacetophenone**; E. Eegriwe, an orange colour with **eriochrom blue black B**, and **eriochrom red B**; F. Feigl, a blue coloration or precipitate with **benzidine**; H. Fischer, a reddish- or bluish-violet colour with **diphenylthiocarbazone**; D. Vitali, a bluish-violet colour with potassium permanganate and **uric acid**; I. M. Kolthoff, a rose-red colour with **diphenylcarbazide**; W. Hieber and F. Leutert, a blue colour with **acetoxime**; R. Berg, a precipitate with o-oxyquinoline; and E. J. Fischer, a blue coloration with **glyoxaline**. K. W. Charitschkoff showed that a benzene soln. of **naphthenic acid** gives an eosin-red with cobalt salts. H. O. Jones and H. S. Tasker found that **potassium dithio-oxalate** gives a deep brown coloration with cobalt salts and a magenta-red with nickel salts sensitive to 1 : 8,000,000. J. L. Danziger obtained a blue colour with **ammonium thioacetate**—R. Schiff and N. Tarugi said that no precipitate is formed in acidic soln., but in ammoniacal soln., cobaltous sulphide is precipitated; and H. Hlasiwetz, T. L. Phipson, and A. del Campo and J. Ferrer, green precipitates with **potassium xanthogenate** or **potassium methylxanthogenate**. C. Vincent obtained blue precipitates with **dimethylaniline** and also with **trimethylamine**.

The metallic precipitation of cobalt.—A. C. Becquerel¹² observed that **copper**, immersed in a soln. of sodium cobalt chloride, acquires a film of cobalt. Z. Roussin observed that magnesium deposits cobalt with the evolution of hydrogen from slightly acidic soln. of cobalt salts. S. Kern noted that with cobalt chloride, a green basic salt is formed; and A. Commaile noted hydrated cobalt hydroxide is precipitated from soln. of the sulphate. According to D. Vitali, when a soln. of a cobalt salt is treated with magnesium, coloured flecks of the hydroxide are formed, and as the action continues, these are gradually reduced to the metallic state—*vide infra*, cobaltous chloride. According to N. W. Fischer, cobalt can be precipitated from soln. of its salts by **zinc** and **cadmium**, but not completely if hydrochloric acid be present, and not at all if nitric acid be present. A. C. Becquerel added that a boiling soln. of cobalt chloride or sulphate and an excess of zinc precipitates all the cobalt as a black powder; and J. L. Davies, and E. A. Demarçay found that the reaction is favoured if the soln. be ammoniacal. According to L. de Boisbaudran, although cobalt is not precipitated from its soln. by metallic zinc, the presence of a metal easily reduced by zinc determines the precipitation of the cobalt. Lead and copper both act in this way, the latter in particular; cadmium does not. The soln. should be very nearly neutral for copper to produce the maximum effect; if the liquid is very acid, the copper alone is deposited. In a soln. rendered very basic by lengthened contact with zinc, the cobalt is not only no longer precipitated, but actually re-dissolves, at the same time an insoluble salt of copper is produced. The addition of a very minute quantity of acid again decolorizes the soln. The cobalt is reduced to the metallic state; the metallic sponge is at first attacked by hydrochloric acid, but the action soon ceases, which indicates an intimate admixture of the copper and cobalt. The reaction was studied by G. Hänsel, A. Grevel, and N. Izgaruishef and I. Mirkin. A. A. Damour found that zinc amalgam deposits cobalt from neutral soln. of cobalt salts. F. Stolba

found that cobalt is deposited on steel or iron by contact with zinc in a boiling soln. of zinc chloride containing a cobalt salt; and C. Mène deposited cobalt on lead, iron, brass, and copper by immersing the metal in contact with zinc in a boiling soln. of zinc chloride containing fragments of cobalt. W. C. Reid observed that **thallium** deposits a basic salt from a soln. of cobalt nitrate.

The physiological action of cobalt salts.—In 1827, G. C. Gmelin¹³ discussed the action of cobalt salts on the animal organism. According to E. Haselhoff, water containing 1 to 2 mgrms. of cobalt per litre exerts a toxic action on vegetation. The subject was discussed by M. Nakamura, and Y. Fukutome. According to J. Bock, the minimum dose of cobalt salts for frogs is 66 mgrms. per kgrm.; for rats, 20 mgrms.; and for guinea-pigs, 16 mgrms. T. Siegen found that 0.1 gm. of cobalt chloride or nitrate killed a frog in half an hour, and 0.3 gm. killed, in 3 hrs., a rabbit weighing 1.5 kgrms. J. Antal observed that only in conc. soln. are cobalt salts poisonous, and that they are quickly given off by the system. Thus, cobalt was detected in the urine 2 hrs. after administration. The subject was also examined by T. P. Anderson and T. P. A. Stuart, and F. Coppola, R. H. Chittenden and C. Norris observed that the poisonous action on rabbits is slow, and manifest only after the administration of relatively large doses. Death is caused by the stopping of the heart, and there also occur enteritis, and an interference with digestive processes. No action was observed on the liver or kidney. Paralysis of the extremities occurs. The cobalt salts form in great measure insoluble compounds with the proteids of the food, and are excreted with the faeces; part enters the circulation and is rapidly distributed to all parts of the body, and is eliminated ultimately in the urine. The body temperature is raised, and the peripheral cutaneous vessels are constricted. Among the organs, the spinal cord and brain stand first in their power of picking up and storing the metal. The muscular tissues also retain a larger percentage of the cobalt than the liver or kidneys. The muscular tissue of the back also retains a larger percentage than that of the legs. The lungs and heart also retain a high percentage of the metal. F. Wohlwill observed that cobalt causes a disturbance of the alimentary tract, and the accompanying nervous symptoms may be due to a direct action on the central nervous system. L. Massol and M. Breton found that the injection of a milligram of cobalt sulphate in the brain of a guinea-pig did not cause death. J. Antal observed that a gram of cobalt nitrate in 1 per cent. soln. had no perceptible effect on rabbits, but a gram in a 5 per cent. soln. killed a rabbit in 24 hrs. According to G. Bertrand and H. Nakamura, nickel and cobalt have a definite effect on animal metabolism; and P. Mascherpa found that when administered orally or subcutaneously, cobalt is absorbed by the organism, and excreted partly by the kidneys, and partly by the intestine. Y. Delage noted that cobalt chloride favours the parthenogenetic *Strongylocentrotus lividus*. C. Gerber studied the action of cobalt salts on the coagulation of milk by proteolytic enzymes. H. W. Armit studied the toxic action of cobalt carbonyl; A. Chassevant and C. Richet, the toxic action of cobalt salts on lactic fermentation; and E. Funk, the action on catalase and amylase ferments. The physiological action of cobalt was studied by G. Bertrand and co-workers, M. Labbé and co-workers, and F. Kraus and T. Brugsch. The physiological effect of some complex cobaltic ammino-salts was studied by J. Bock, and A. Oswald. Cobaltous nitrate has been used in subcutaneous injections, as an antidote to poisoning by cyanide.

The uses of cobalt.—Cobalt is not in extensive use.¹⁴ Cobalt oxide is used for colouring enamels, glasses, and pottery, and other glazes blue. It is valuable for this purpose because the colour is stable in the presence of silicates, and at a high temp. Cobalt oxide, or, less frequently, smalt, is also used in preparing underglaze colours for producing the ultramarine type of blue—e.g., the so-called willow pattern; for tinting other colours; or for the so-called matt blue which approximates to the turquoise blue, and has cobalt aluminate as the basal stain. Cobalt oxide diluted with a large proportion of clay or flint and calcined, or a soluble cobalt

salt, is used as a stain to counteract or mask the cream colour produced by the traces of "iron" in the raw materials. Several preparations of cobalt have been used as pigments for painting. Their covering power is poor, and although they are usually very permanent, their comparatively high cost prevents them taking the place of other pigments.

A blue glass prepared in Saxony since the sixteenth century,¹⁵ under the name *smalt*, *bleu d'azur*, or *bleu de saxe*, is essentially a potassium silicate glass coloured with cobalt. T. I. Bowler described the manufacture of smalt in China. In Saxony, the bismuth ferrous ore is heated to separate the bismuth by liquation; the crushed product is roasted to furnish a crude oxide called *zaffre* or *zaffler*. The zaffre is mixed with potassium carbonate and ground quartz or sand, and fused to a glass. The impurities settle at the bottom, and the blue glass is ladled off with iron spoons, and poured into cold water. The glass is then ground to powder, levigated, dried, and sifted. A cobalt aluminate blue, called *cobalt-blue*, *Thénard's blue*, *cobalt ultramarine* or *King's blue*, is prepared by calcining mixtures of cobalt oxide and alumina or ammonia-alum, or potash-alum. In the last case, the product is washed to remove the alkali sulphate. According to J. J. Berzelius,¹⁶ the effect of alumina on the colour produced by cobalt was noticed by J. G. Gahn in 1777, and later by C. F. Wenzel. Zinc oxide, and phosphate may be added to the mixture before calcination. The original Thénard's blue was made with a cobalt phosphate or arsenate and alumina, but now the cobalt-aluminium blue has often the same designation.

The so-called *cerulean blue*, or *bleu célestique*, is produced by heating a mixture of cobalt sulphate, tin oxide, and precipitated silica or chalk. The green colour, called *Rinnman's green*, *zinc green*, or *cobalt green*—*vide infra*, zinc percobaltite—is prepared by firing a mixture of cobalt and zinc oxides. The bluish-green pigment, called *turquoise green*,¹⁷ is made by firing a mixture of cobalt oxide, chromic oxide, and alumina. The so-called *Indian yellow*, *aureolin*, or *cobalt yellow*, is potassium cobaltic nitrite—*vide* 8. 49, 38. The so-called *cobalt brown* is produced by calcining a mixture of ammonium, ferrous and cobalt sulphates. Cobalt arsenate or phosphate, when ground, furnishes a pink colour.¹⁸ The calcination of precipitated magnesium carbonate stained with cobalt nitrate, furnishes the so-called *cobalt magnesite pink*; ¹⁹ and *cobalt bronze* is a violet ammonium cobalt phosphate with a bronze lustre.

A dil. soln. of the pink cobalt salts—chloride or nitrate—is used as a *sympathetic ink*,²⁰ *vide supra*—the writing on paper is invisible except when the paper is warmed. The anhydrous blue becomes invisible as the paper is cooled and atm. moisture is absorbed. Cobalt nitrate is used as a blowpipe reagent to assist in the recognition of compounds of aluminium, zinc, and magnesium. Some organic compounds of cobalt—*e.g.*, resinate, oleate, and acetate—have been used to facilitate the "drying" of oils, paints, and varnishes. A. and L. Lumière and A. Seyewitz²¹ experimented on the toning of photographic plates with cobalt. The Nya Akkumulator Aktiebolaget experimented on the use of cobalt for the electrodes of accumulators; and R. Langhans, as a constituent in preparing thoria incandescent mantles. M. Baum deposited platinum on cobalt plating.

Owing to its pleasing colour, hardness, and resistance to tarnish, cobalt offers possibilities in electroplating, and in making coins. Cobalt is also employed in making alloys. The Fe_2Co -alloy has valuable magnetic qualities, discussed by H. T. Kalmus and K. B. Blake.²² Cobalt steels for magnets have been described by K. Honda and S. Saito. There are also special alloys with various trade names—*e.g.*, *iridium* is a cobalt-tungsten-chromium steel with less than 1 per cent. each of vanadium, molybdenum, and carbon; *stellite*, described by E. Haynes, was originally a chromium-cobalt (1 : 3) alloy. These alloys resist corrosion very well. Stellite was afterwards made with up to about 25 per cent. of tungsten, and also molybdenum. They are used for lathe tools. The so-called *cochrome* is a cobalt-chromium alloy used for electrical resistance wires. A cobalt-tin alloy is brittle but resists attack by acids. Cobalt is also added to strengthen brass, and

aluminium alloys. Cobalt amalgam is used in dentistry. The uses of cobalt alloys were described by J. Aston, W. R. Barklay, W. S. Barrows, L. Guillet, E. A. Watson, A. Haenig, etc.—*vide infra*.

§ 8. The Atomic Weight and Valency of Cobalt

W. Manchot and co-workers,¹ G. Grube, and L. Cambi and co-workers discussed the possibility of the existence of *univalent cobalt* in the nitrosyls; and the valency of cobalt was discussed by E. Thilo. Cobalt behaves as a *bivalent* element in the so-called cobaltous salts typified by cobaltous chloride, CoCl_2 , which is unimolecular in pyridine soln., and bimolecular in urethane soln. This also is in agreement with the vapour density of cobaltous acetylacetonate, $\text{Co}(\text{C}_5\text{H}_7\text{O}_2)_2$; and with the isomorphism of the zinc, magnesium, manganese, and cobaltous sulphates of the type $\text{MSO}_4 \cdot 6\text{H}_2\text{O}$, discussed by W. Stortenbecker. Cobalt also behaves as a *tervalent* element in the so-called cobaltic salts. This is illustrated by the cobaltic acetylacetonate, $\text{Co}(\text{C}_5\text{H}_7\text{O}_2)_3$, of G. Urbain and A. Debierne, who found that the salt is unimolecular in benzene soln. This is also confirmed by the existence of the cobaltic alums, and by the isomorphism of the potassium complex cyanides, K_3CoCy_6 , K_3MnCy_6 , and K_3FeCy_6 . Determinations of the mol. wts. of the cobaltic ammines by the f.p. method, and observations on the electrical conductivities, etc., by S. M. Jörgensen, J. Petersen, A. Werner and A. Miolati, and W. Biltz agree with the assumption that the contained cobalt is tervalent. The double sulphates or alums of the type $\text{R}_2\text{SO}_4 \cdot \text{Co}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$, studied by H. Copaux, J. L. Howe and E. A. O'Neal, and H. Marshall, isomorphous with the corresponding alums of tervalent iron, chromium, aluminium, and some of the platinum metals, all support the tervalency of cobalt. There are indications of a still higher valency in the so-called cobaltous acid, H_2CoO_3 , and its salts observed by A. H. McConnell and E. S. Hanes, and E. Dufau; or the more doubtful cobaltic acid, H_2CoO_4 .

According to N. V. Sidgwick, the highest co-valency of the atoms of the elements up to the end of the first long period of the periodic classification is 6. E. G. V. Percival and W. Wardlaw attributed a co-valency of 4 to some double salts of cobaltous chloride with quinoline, and pyridine. R. Weinland quoted A. Pieroni and A. Pinotti's complex salt as an example of a compound whose **co-ordination number** is 8 not 6, but W. R. Bucknall and W. Wardlaw showed that the original formulation of the salt was wrongly stated to be $[\text{Co}(\text{C}_3\text{H}_5 \cdot \text{NH}_2)_3]\text{Cl}_3$, it should be:

T. M. Lowry, and H. Reihlen discussed the subject. A. Werner prepared a series of optically active compounds of cobalt which show that their structure is asymmetric. P. Karrer, A. F. Richter, and A. Werner discussed the valency isomerism of cobalt.

Up to the year 1857, the generally accepted value for the at. wt. of cobalt was 58.9. The datum 58.9 due to J. J. Berzelius,² was based on the analysis of cobalt chloride; and it was found to be in agreement with the observations on the valency of cobalt, with the sp. ht., and with the isomorphism of various cobalt salts with salts of related elements. T. Thomson attempted to find the at. wt. of cobalt in 1821. The observed values for the at. wts. of iron (55.84), cobalt (58.97), and of nickel (58.68), do not fit in with the periodic law of D. I. Mendeléeff, for the at. wt. of cobalt should be less, not greater, than that of nickel, and greater than that of iron. This difficulty was attributed by H. Remmler, and G. Krüss and F. W. Schmidt to the presence of an unknown element, *gnomium*, but all attempts to establish the existence of the hypothetical element proved nugatory, and the hypothesis was abandoned. C. Winkler, however, considers that the difficulties with the

above-cited investigators were due to impurities derived from the glass vessels, and was unable to confirm their results. Hence he concludes: "I cannot believe that nickel contains a hitherto unknown substance differing in properties and atomic weight; on the contrary, I consider both nickel and cobalt to be simple substances, and elements in the present sense of the word." C. Zimmermann, H. Remmler, P. Schützenberger, R. Vogel, and A. Sakoschansky discussed the place of cobalt in the periodic system. F. H. Parker and F. P. Sexton stated that in some electrolytic comparisons of cobalt and silver, they obtained 57.7 as a mean value for the at. wt. of cobalt, which is lower than that of nickel. The atomic numbers by H. G. J. Moseley, the lattice constants of T. Barth and G. Lunde, the m.p., and the cathode and anodic polarizations of R. Schilb, all agree with a position for cobalt between iron and nickel; F. K. Richtmyer and F. W. Warburton, J. J. Thomson, and C. G. Barkla and C. A. Sadler found that the permeability of metals for the X-rays is a periodic function of the at. wts. of the elements, and by interpolation, they obtained 61.2 to 61.6 for the at. wt. of nickel. S. Meyer, and O. Liebke, and H. du Bois concluded that the at. wt. of cobalt is less than that of nickel because of its paramagnetic properties. These conclusions, said F. W. Clarke, "cannot weigh very heavily against the clear chemical evidence" of the misfit in the periodic table—1. 6, 5.

In 1857, E. R. Schneider determined the carbon dioxide evolved during the ignition of the oxalate, and from the ratio $\text{Co} : 2\text{CO}_2 = 100 : 146.665$, obtained 60.05 for the at. wt. of cobalt and about 58 for that of nickel. J. C. G. de Marignac, in 1858, found, in opposition to E. R. Schneider, that the at. wts. of cobalt and nickel are nearly the same. By calcining the sulphate to oxide, he obtained $\text{CoSO}_4 : \text{CoO} = 100 : 48.287$, or 58.761 for the at. wt. of cobalt; and by analyzing cobalt chloride for chlorine, by titration with silver nitrate, he obtained $2\text{Ag} : \text{CoCl}_2 = 100 : 60.118$, or 58.797 for the at. wt. J. B. Dumas' analyses of cobalt chloride gave 59.034 for the at. wt.; and C. Winkler's, 59.776. C. Winkler analyzed cobalt chloride gravimetrically, and from the ratio $2\text{AgCl} : \text{Co} = 100 : 20.864$, calculated 59.812 for the at. wt. W. Hempel and H. Thiele likewise obtained 58.929; by the synthesis of the chloride they obtained from the ratio $\text{Cl}_2 : \text{Co} = 100 : 82.873$, and the at. wt. 58.769; and by the synthesis of the iodide, they calculated from the ratio $\text{I}_2 : \text{Co} = 100 : 23.462$, the at. wt. 59.556. T. W. Richards and G. P. Baxter obtained from the synthesis of the chloride, $\text{Cl}_2 : \text{Co} : 100 : 83.266$, or 59.047 for the at. wt.; from the ratio $2\text{Ag} : \text{CoBr}_2 = 100 : 101.407$, $\text{Co} = 58.964$; from $2\text{AgBr}_2 : \text{CoBr}_2 = 100 : 58.255$, or $\text{Co} = 58.969$; and from $\text{CoBr}_2 : \text{Co} = 100 : 26.952$, $\text{Co} = 58.972$. G. P. Baxter and F. B. Coffin obtained $2\text{Ag} : \text{CoCl}_2 = 100 : 60.1975$, or $\text{Co} = 58.968$; and $2\text{AgCl} : \text{CoCl}_2 = 100 : 45.3070$, or $\text{Co} = 58.969$.

W. J. Russell dissolved the metal in hydrochloric acid, and measured the hydrogen evolved, and from the ratio $\text{Co} : \text{H}_2 = 100 : 3.4112$, he calculated $\text{Co} = 59.077$. W. J. Russell also reduced cobaltous oxide by heating it in hydrogen, and from the ratio $\text{CoO} : \text{Co} = 100 : 78.592$, he calculated $\text{Co} = 58.738$. C. Zimmermann likewise obtained $\text{Co} = 58.889$; H. Remmler, 59.812; W. Hempel and H. Thiele, 58.769; and T. W. Richards and G. P. Baxter, 58.973. C. Winkler measured the gold precipitated by cobalt from soln. of sodium chloroaurate, and from the ratio $2\text{Au} : 3\text{Co} = 100 : 45.172$, calculated $\text{Co} = 59.386$.

E. von Sommaruga analyzed the pentamminochloride, and obtained from the ratio $\text{Co}(\text{NH}_3)_5\text{Cl}_3 : \text{Co} = 100 : 23.827$, the at. wt. $\text{Co} = 59.909$; R. H. Lee likewise obtained $\text{Co} = 59.095$. P. Weselsky analyzed ammonium cobaltcyanide, and calculated from the ratio $(\text{NH}_4)_3\text{CoCy}_6 : \text{Co} = 100 : 21.943$, the at. wt. $\text{Co} = 59.085$; and similarly with phenylammonium cobaltcyanide, obtained the ratio $(\text{C}_6\text{H}_5\text{NH}_2)_3\text{CoCy}_6 : \text{Co} = 100 : 11.8665$, from which he calculated the at. wt. $\text{Co} = 59.017$. R. H. Lee obtained from brucine cobaltcyanide, $(\text{C}_{23}\text{H}_{26}\text{N}_2\text{O}_4)_3\text{H}_3\text{CoCy}_6 \cdot 10\text{H}_2\text{O} : \text{Co} = 100 : 3.7437$, or $\text{Co} = 59.1991$; and from strychnine cobaltcyanide, $(\text{C}_{21}\text{H}_{22}\text{N}_2\text{O}_2)_3\text{H}_3\text{CoCy}_6 \cdot 4\text{H}_2\text{O} : \text{Co} = 100 : 4.5705$, or $\text{Co} = 59.096$.

From the results available in 1910, F. W. Clarke calculated for the best representative value 58.961. G. P. Baxter and co-workers obtained 58.940 for the best representative value of terrestrial cobalt, and 58.942 for meteoric cobalt. The results of T. W. Richards and co-workers give 58.97 for the at. wt. of cobalt, and 58.94 is the value adopted by the International Committee for 1931. The at. wts. of the family of elements was discussed by G. D. Hinrichs, and M. Gerber.

The **atomic number** of cobalt is 27, when that of iron is 26, and that of nickel 28. P. Vinassa³ studied the molecular numbers of cobalt compounds; and D. de Barros, the nuclear numbers. F. Sanford discussed the relations between the atomic numbers and the physical and chemical properties of the elements; A. F. Scott, between the numbers and the ionic properties in the crystal lattice; and M. Kahanovicz, between the atomic numbers and the elastic constants. According to F. W. Aston, there are no **isotopes**, since only one kind of atom of mass 59 has been observed, although A. S. Russell anticipated an isotope of mass 57 from his study of the isotopes of radioactive and non-radioactive elements. T. R. Bull and S. S. Cooper studied the isotopes of cobalt. E. Rutherford and J. Chadwick, and J. D. Cockroft and E. T. S. Walton have not reported any definite evidence of **atomic disruption** by the bombardment of cobalt with α -particles, although H. Pettersson and G. Kirsch said that there is evidence of a slight disruption of the atom.

N. Bohr, and E. C. Stoner represented the **electronic structure** of the atom on the assumption that the electrons present are (2) for the K-shell; (2, 2, 4) for the L-shell; (2, 2, 4, 3, 4) for the M-shell; and (2) for the N-shell. The electronic structure was discussed by C. M. Blackburn, H. Collins, O. Feussner, P. D. Foote, H. Grimm, W. D. Harkins, W. Kimura, R. Ladenburg, A. E. Lacomblé, H. Lessheim and co-workers, G. N. Lewis, L. W. McKeegan, S. Meyer, P. Niggli, C. D. Niven, H. Perlitz, N. S. Grace, G. I. Pokrowsky, P. R. Ray, W. H. Rothery, A. S. Russell, M. N. Saha, M. N. Saha and B. B. Ray, R. Samuel and E. Markowicz, J. D. M. Smith, A. Sommerfeld, R. Sonder, D. Strömholm, R. Swinne, A. T. Williams, H. J. Walke, E. Fermi, P. D. Foote, H. Kopfermann and E. Rasmussen, and L. Zehnder. The electronic structure of complex salts was discussed by D. M. Bose, C. J. Brockman, B. Cabrera, R. H. Fowler, M. L. Huggins, L. C. Jackson, H. Lessheim and co-workers, T. M. Lowry, C. D. Nenitzesco, P. R. Ray, N. V. Sidgwick, C. H. Spiers, P. Weiss, and L. A. Welo and O. Baudisch; the relation between the fusibility and electronic structure, by P. Vinassa; between the heat of dissolution and the valency electrons, by A. F. Richter; the energy of the electronic combination, by E. A. Milne; the relation between the electronic structure and electrical conductivity, by L. Bloch, D. P. R. Chaudhury, J. C. McLennan and co-workers, J. W. Nicholson, and M. N. Saha and B. B. Ray; the electron structure and the passive state, by A. S. Russell and co-workers, and R. Swinne; and the relation between the electron structure and magnetization, by D. M. Bose, B. Cabrera, J. Dorfman and R. Jaanus, M. L. Huggins, L. C. Jackson, R. Ladenburg, H. Lessheim and co-workers, L. W. McKeegan, P. R. Ray, A. Sommerfeld, R. Swinne, P. Weiss, and L. A. Welo and O. Baudisch.

§ 9. Intermetallic Compounds or Alloys of Cobalt

According to G. Guillemin,¹ **copper-cobalt alloys** are readily obtained by melting the two metals together under a flux of boric acid and wood-charcoal, or by melting copper with an alloy of copper and cobalt formed in the process of copper smelting. N. S. Konstantinoff melted the mixed metals in a magnesia crucible in an electric furnace in an atm. of hydrogen or nitrogen; and R. Sahmen melted them in a porcelain tube in an atm. of dry hydrogen. J. Jahn reduced the mixed oxides by hydrogen, and also by aluminium in the thermite process. D. S. Ashbrook found that copper mixed with cobalt is deposited electrolytically from an electrolyte containing 0.25 grm. of metal per 1 c.c. of conc. sulphuric acid, or 10 c.c. of phosphoric acid of sp. gr. 1.085, and 50 c.c. of a 10 per cent. soln. of sodium hydrophosphate, using a rotating anode. The observations of W. Guertler, L. Guillet, N. S. Konstantinoff, A. Neuburger, F. Ducelliez, and R. Sahmen give no indication of the formation of definite chemical compounds, but give either homogeneous solid soln., or two-phase systems of solid soln. G. Tammann and W. Oelsen observed that the solubility, S per cent., of cobalt in copper can be represented by $\log S = -2269T^{-1} + 2.343$, and they found by extrapolation at 20°, $S = 0.054$, and that at :

FIG. 35.—Freezing-point Curves of the System: Copper-Cobalt.

	1070°	985°	800°	690°	502°	442°
S . . .	4.51	3.52	1.72	0.94	0.26	0.22

R. Sahmen's freezing-point curve is shown in Fig. 35. The metals form two series of solid soln. with 0 to 10 per cent. and 95.5 to 100 per cent. of copper respectively. There is a break in the cooling curve at 1100° with alloys having 10 to 95 per cent. of copper, below which the alloy solidifies completely to a conglomerate of two series of solid soln. On cooling, the β - or non-magnetic cobalt changes to the ordinary α - or magnetic form. The transition temp. is lowered from 1115° for purified cobalt to 1050° by the addition of 10 per cent. of copper; it remains constant at 1050° for alloys, with up to 90 per cent. of copper; and then falls with the further addition of copper. Alloys with 99 per cent. of cobalt are still magnetic. N. S. Konstantinoff said that as cobalt is added to copper, the f.p. is raised so that the f.p. curve has four branches indicating the existence of solid soln. The break with 6.5 per cent. of cobalt represents a sat. soln. of cobalt in copper; and there

are also breaks corresponding with 30 and 70 per cent. of cobalt. The copper forms a solid soln. with up to 85 per cent. of cobalt; and alloys with 30 to 70 per cent. of cobalt form two layers in the liquid state. L. Vegard and H. Dale found that, unlike the alloys with nickel, those with cobalt form two series of solid soln. Alloys with 100, 75, 50, and 25 per cent. of copper have lattice constants respectively $a=3.61$, 3.60 , 3.60 , and 3.60 A., and those with 50, 25, and 0 per cent. of copper they may have, respectively, $a=3.539$, 3.539 , and 3.533 A. R. Sahmen said that the maximum in the thermoelectric force with about 97 per cent. of copper, and W. Guertler, that the maximum in the electrical conductivity curve for about 95 per cent. copper, represent a sat. solid soln.

According to G. Guillemin, alloys containing 1 to 6 per cent. of cobalt have a red colour and a fine, silky fracture resembling that of copper. According to N. S. Kurnakoff and S. F. Schemtschuschny, the alloys may contain dendrites of cobalt. H. Behrens said that the alloys with 20 per cent. of copper have a fine-grained, crystalline structure, and when etched with 50 per cent. sulphuric acid they show a pale red, irregular network in a brownish-red matrix which also contains small, grey granules of an alloy rich in cobalt. L. Vegard and H. Dale found that the cubic lattice of cobalt is stabilized by copper. R. Sahmen observed that the fracture of alloys with over 15 per cent. of copper is red, and the hardness of the solid soln. rich in copper is 3, and that of solid soln. rich in cobalt is 4. M. Waehlert found Brinell's hardness of the alloys to be:

Copper	100	90	80	70	60	50	40	30	20	10 per cent.
Hardness	28	75	81	103	106	112	124	130	135	180

M. G. Corson, A. W. Smith, and C. S. Smith discussed the mechanical properties of the air-hardened alloys. A. Valenciennes said that the annealed alloys are ductile, and G. Guillemin observed that alloys with 1 to 6 per cent. of cobalt are remarkably ductile, malleable, and tenacious; they can be worked and rolled in the cold, but they cannot be tempered; they break under a tensile strain of 25 to 36 kgrms. per sq. mm., and have an elongation of 15 to 28 per cent. An alloy with 5 per cent. of cobalt, after forging and rolling, broke under a strain of 40 kgrms. per sq. mm. and had an elongation of 10 per cent. This alloy was as malleable and as little liable to oxidation as copper, and was as ductile and tenacious as iron.

The effect of small quantities of cobalt on the electrical properties of copper was found by G. Reichardt to be almost as great as that of manganese, and about three times as great as that of nickel. W. Guertler stated that there is a sharp break in the sp. electrical resistance curve of alloys with 5 vol. per cent. of cobalt. G. Reichardt observed that the sp. resistance of copper increases rapidly with additions of up to 3.2 per cent. of copper and attains 9.5 microhms per cm. cube. The results are indicated in Table II, where the sp. resistance is expressed in

TABLE II.—SOME PROPERTIES OF THE COBALT-COPPER ALLOYS.

Cobalt per cent.	R microhms	Temp. coeff.	Thermal e.m.f. $\times 10^6$	Cobalt per cent.	R microhms	Temp. coeff.	Thermal e.m.f. $\times 10^6$
0	1.672	0.004450	—	23.6	11.43	0.000817	26.5
1.5	6.76	0.001084	30.8	34.4	12.10	0.000936	25.9
1.9	8.80	0.000859	32.1	46.6	11.34	0.00132	20.8
3.1	9.45	0.000768	33.0	59.4	12.92	0.00143	19.4
4.1	9.45	0.000771	32.1	70.3	14.79	0.00150	18.5
5.1	8.63	0.000820	32.8	80.5	16.57	0.00166	17.6
6.7	10.02	0.000801	31.5	90.4	24.30	0.00167	16.7
13.9	10.72	0.000776	29.1	99.8	9.73	0.00326	26.8

microhms per cm. cube at 20° ; then follows the temp. coeff. of the resistance; and finally, the thermal e.m.f. against copper is expressed in 10^{-6} volt per degree.

The addition of 3 to 5 per cent. of cobalt gives an alloy with a minimum temp. coeff. of the resistance of 0.00077, and a maximum thermoelectric effect of 33 microvolts for 1 degree difference of temp. Up to this proportion of cobalt, the sp. resistance of the alloys increases rapidly, but a further addition of cobalt produces only a slow increase of resistance. The sp. resistance has a maxima with between 3 and 4 per cent., and about 34.4 per cent. of cobalt. The alloys can be used in making thermoelectric couples. All the cobalt-copper alloys, except those containing less than 1.5 per cent. of cobalt, can be magnetized, and the magnetism is destroyed only at a red-heat. W. Broniewsky discussed the thermoelectric force.

R. Sahmen observed that the magnetism disappears at 1115° with 100 per cent. cobalt, Fig. 35; at 1050°, with 10 per cent. copper, and it then remains constant for alloys with up to 90 per cent. copper; it falls to 950° for alloys with 95 per cent. copper, and thereafter falls rapidly. G. Tammann and W. Oelsen measured the specific magnetization (gauss) of copper-cobalt alloys containing the following proportions of dissolved and total cobalt:

		1070°	1010°	890°	690°	392°	20°
Dissolved Co		4.51	3.75	2.51	0.94	0.22	0.220
Gauss	0.50 per cent. Co	0.01	0.002	0.001	0.002	0.390	0.390
	1.00 " Co	0.002	0.004	0.003	0.128	1.230	1.23
	5.00 " Co	0.698	1.68	3.98	6.44	7.33	7.34
	22.5 " Co	26.6	27.0	30.2	32.9	33.8	33.7

G. Tammann observed that the temp. of the magnetic transformation of cobalt is lowered 30° by the addition of 5.2 per cent. of copper; and he suggested that the magnetizability of the alloys rich in copper is conditioned by the presence of crystals of a solid soln. rich in cobalt. A. Kussmann and B. Scharnoff studied the coercive force of the alloys.

W. Guertler and T. Liepus found that a 10 per cent. soln. of sodium hydroxide had no attack on the 1 : 1-alloy in 8 hrs., but with a 15 per cent. soln. the metal was attacked. The alloy was also attacked in 8 hrs. by 10 and 50 per cent. nitric acid; by 10 and 36 per cent. hydrochloric acid; aqua regia; 10 per cent. sulphuric acid; 20 per cent. sulphuric acid sat. with sodium sulphate; sodium hydroxide and hydrogen dioxide, 10, 50, and 70 per cent. aq. ammonia; 10 and 50 per cent. sodium sulphide, and 4 per cent. sodium sulphide mixed with 8 per cent. of alkali; chlorine water; sea-water; sea-water plus air; rain-water and air; and a soln. of magnesium chloride. A 1 : 500-soln. of mercuric chloride was not stable in contact with the alloy. According to M. Waehlert, the losses in mgrms. per sq. mm. of the alloys when exposed to nitric and sulphuric acids of different concentration, in percentages, for the time in hours stated in brackets, are:

Copper	90	80	70	60	50	40	30	20	10%
HNO ₃	1 (48)	0.67	0.42	0.36	0.42	0.60	0.65	—	—

	30 (24)	0.17	—	—	—	0.07	—	—	—
	50 (24)	0.08	—	—	—	0.07	—	—	—

According to G. J. Petrenko,² **cobalt-silver alloys** cannot be prepared below 1600°, for up to this temp. the two elements are completely insoluble in one another. K. Masaki prepared alloys by electrodeposition. E. Pannain said that if alloyed with a third metal, silver and cobalt furnish alloys containing the three metals in various proportions; F. Ducelliez found silver to be insoluble in cobalt, so that when the two metals are melted together, say 95 per cent. of silver, on cooling virtually

pure silver separates out, and a metal containing 80.77 per cent. of silver. When an ingot with 70.25 per cent. of silver is liquated, at a temp. between the m.p. of the two metals, pure silver was obtained, and the lower part of the ingot became richer in silver. No evidence of a eutectic was observed; and G. J. Petrenko found that the two breaks in the cooling curve corresponded respectively with the m.p. of cobalt and of silver. W. Oelsen found that silver dissolved 5.5×10^{-4} per cent. of cobalt. According to F. Ducelliez, after etching the alloys with hydrochloric acid, the surfaces showed (i) grey zones, often elongated, and rich in silver; and (ii) bright zones corresponding with silver. With $N\text{-CoSO}_4$, the alloys gave no e.m.f. with cobalt poles, but gave a constant e.m.f. of 0.535 volt with silver poles. All the alloys were magnetic; and all were attacked by hydrochloric acid—those rich in cobalt leaving silver powder; those moderately rich in cobalt giving lamellæ of silver; whilst those poor in cobalt retained their shape, but became brittle, and after treatment with acid, they could be broken up by a hammer.

C. Hatchett³ found that the dark yellow **cobalt-gold alloy**, with 18 parts of gold and 1 part of cobalt, is brittle and possesses a pale yellow fracture; an alloy

FIG. 36.—Freezing-point Curves of Cobalt-Gold Alloys.

with $\frac{1}{65}$ th of cobalt is brittle, but with $\frac{1}{115}$ th of cobalt is malleable. Alloys were also prepared by Richter and Co., and E. Jänecke. According to W. A. Wahl, molten cobalt and gold can be mixed in all proportions. The alloys show the same phenomena on melting as those shown by cobalt alone—*vide supra*. The f.p. curves, Fig. 36, have two branches meeting at a eutectic at 997° and 72.9 at. per cent., or 90 per cent. of gold. Solid soln. containing 0 to 5.5 per cent., and 96.5 to 100 per cent. of cobalt are formed. The crystals rich in cobalt must be cubic above 1140°, being isomorphous with β -cobalt; and hexagonal below that temp., corresponding with α -cobalt. All the alloys are magnetic, and the magnetizability falls with increasing proportions of gold, rapidly at first, and then more slowly; it increases with the temp., being three times as great at the eutectic temp. as in the cold. J. O. Linde studied the electrical resistance of the alloy; and G. Borelius and co-workers, the thermoelectric properties.

H. N. Warren⁴ prepared a **calcium-cobalt alloy** by reducing cobalt oxide with calcium carbide; and M. Tarugi, by reducing cobalt salts with the same reagent. G. Masing, and W. Hessenbruch, prepared **beryllium-cobalt alloys**. The cementation of cobalt with beryllium was studied by I. Fetchenko-Tchopivsky, who found that beryllium is insoluble in cobalt below 1300°. G. Masing and O. Dahl said that beryllium is sparingly soluble in cobalt at a high temp., and even less soluble on a falling temp. The hardness and tensile properties may be increased by quenching and ageing at suitable temp.

J. Parkinson⁵ could not obtain **magnesium-cobalt alloys** by melting a mixture of the component metals. A. F. Gehlen prepared a grey **cobalt-zinc alloy** with a metallic lustre by heating a mixture of cobalt and zinc turnings (1 : 2). C. Gourdon, B. Egeberg, and F. Ducelliez also obtained an alloy of the two metals. Alloys were obtained by simultaneous electrodeposition from aq. soln. of the component salts by R. Kremann and co-workers, by R. Müller and F. R. Thoïs, and by S. Glasstone. K. Lewkonja obtained crystals of solid soln. with proportions of cobalt ranging from 0.5 to 18.5 per cent. The sat. solid soln. contains 13.4 per cent. of cobalt. The eutectic, according to K. Lewkonja, is 5° below the m.p. of zinc, and, according to W. M. Peirce, 1° below the m.p. There is evidence, Fig. 37, of the formation of a non-magnetic **cobalt tetrazincide**, CoZn_4 . The subject was studied by N. Parravano and V. Caglioti, and L. Guillet; and A. R. Russell and co-workers studied the compounds formed in mercury soln. A. Westgren studied the X-radiogram of the **cobalt pentitadizincide**, Co_5Zn_2 , and also the

relation between the crystal structure and atomic properties of the cobalt-zinc alloys. A. J. Bradley, and W. Ekman studied the X-radiograms, and they preferred the formula Co_5Zn_2 to CoZn_4 . F. Ducelliez also obtained the alloy by melting zinc with 18.46 per cent. of cobalt. The sp. gr. is 7.43 at 0° when the calculated value is 7.11. The e.m.f. of the cell $\text{Zn} : \text{N-ZnSO}_4 :$

Co_nZn_m decreases slowly with increasing cobalt up to 20 per cent. cobalt, and it then rises very rapidly. The cell $\text{Co} : \text{N-ZnSO}_4 : \text{Co}_n\text{Zn}_m$ behaves similarly. The break in the e.m.f. curve is supposed to correspond with the tetrazincide. S. Glasstone found the deposition potentials of cobalt and zinc from soln. of the two sulphates. K. Lewkonja said that alloys with no more than 20 per cent. of cobalt are not ferromagnetic; and F. Ducelliez, that alloys rich in cobalt are ferromagnetic. When the tetrazincide is heated in hydrogen, the zinc evaporates. The powdered alloy oxidizes quickly

FIG. 37.—Freezing-point Curves of Zinc-Cobalt Alloys.

in air at ordinary temp., and it burns at a red-heat in air, or in contact with molten potassium chlorate. It is attacked by boiling water. It is attacked by chlorine at a dull red-heat with incandescence. One per cent. hydrochloric acid attacks the tetrazincide in the cold; and alloys with over 83 per cent. of zinc leave finely-divided cobalt as a residue when treated with boiling dil. acid, and with cold, 1 per cent. hydrochloric acid a residue of the tetrazincide remains, and with alloys having 11.7 to 78 per cent. of zinc, the residue has approximately the same composition as the original alloy—similarly also with 1 per cent. nitric acid. The tetrazincide reacts vigorously with liquid or the vapour of sulphur; it is attacked by cold, 1 per cent. sulphuric acid, and 1 per cent. nitric acid; it is attacked by molten alkali hydroxides, carbonates, or nitrates. Soln. of cobalt sulphate or chloride dissolve zinc from the tetrazincide—particularly with hot soln.—and leave a ferromagnetic residue, but the zinc is not dissolved by soln. of cobalt nitrate. J. Jahn found that the **cobalt-zinc-copper alloys**, or cobalt brasses, analogous to nickel-silver (*q.v.*), with cobalt in place of nickel, are silver-white, brittle, and hard. The alloys are attacked rather more when heated with hydrogen sulphide, and sulphur dioxide than is the case with the nickel silvers. Observations were made by L. Guillet, D. Iitsuka, and W. M. Peirce. C. Browne observed that the addition of cobalt to 80:20-copper-zinc alloy raised the tensile strength considerably. Thus, with wires 0.7 mm. in diameter:

Cobalt	0	0.12	0.21	0.50 per cent.
Tensile strength . .	26.1	28.0	29.9	31.2
Percentage increase .	—	9.2	14.6	19.6 per cent.

K. Lewkonja also prepared some **cobalt-cadmium alloys**. He found that the f.p. of cadmium is lowered 6° by the addition of cobalt, and the eutectic furnishes a mass containing crystals which are either a compound of the two elements, or else crystals of a solid soln. sat. with cadmium, because the alloys with up to 10 per cent. of cobalt are non-magnetic at room temp. A. S. Russell and co-workers observed that no compounds are formed in mercury soln. R. Kremann and co-workers, and R. Müller and F. R. Thois prepared alloys by electrodeposition.

R. Böttger,⁶ C. F. Schönbein, J. Schumann, and H. Moissan prepared **cobalt-mercury alloys**, or **cobalt amalgams**, from sodium amalgam and a conc. soln. of cobalt chloride, at the same time the liquid becomes violet owing to the separation of cobaltous hydroxide. W. Kettembeil also prepared cobalt amalgam by the action of potassium amalgam in soln. of cobaltous chloride sulphate, or nitrate. A. A. Damour immersed zinc amalgam—1 part of zinc and 6 parts of mercury—in an aq. soln. of cobaltous chloride, sat. with ammonia. Hydrogen is evolved. The liquid over the amalgam is renewed as often as it loses its colour. The zinc in the cobalt amalgam can be extracted by boiling dil. sulphuric acid, which does

not act on the cobalt amalgam. Aq. soln. of cobaltous sulphate or chloride do not act so quickly as the ammoniacal soln. of the chloride, and aq. soln. of cobalt nitrate give nothing but hydrated cobaltous oxide. P. Casamajor obtained cobalt amalgam by the process used for iron amalgam (*q.v.*), that is, by shaking up cobalt with sodium amalgam and dil. acid. H. Moissan, and J. Schumann prepared the amalgam by electrolyzing a soln. of cobaltous chloride with a platinum anode, and a mercury cathode; H. Nagaoka similarly electrolyzed a soln. of cobaltic chloropentamminochloride; L. Paraskovich, and R. Erban and L. Paraskovich, a soln. of ammonium cobaltous sulphate and boric acid; and A. S. Russell and co-workers, a soln. of cobaltous sulphate in $4N\text{-H}_2\text{SO}_4$. G. Tammann and co-workers gave 1.7×10^{-1} , and N. M. Irvin and A. S. Russell, $< 8 \times 10^{-5}$ grm. per 100 grms. of mercury for the solubility of cobalt. J. Schumann prepared an amalgam electrolytically corresponding with $\text{Hg}_{10}\text{Co}_3$.

According to R. Böttger, the amalgam is less fluid than mercury, and is not affected by a magnet until a part of the mercury has been driven off by heat. J. Schumann found that the amalgam prepared by R. Böttger's process contains, besides the silver-white liquid amalgam, hard crystals of a darker colour. R. Böttger found that when the amalgam is heated, there remains a black residue of cobalt and its oxide. A. A. Damour said that when the amalgam is heated in a closed vessel, the mercury is given off, leaving the cobalt in the form of a grey, metallic mass—*vide supra*, pyrophoric cobalt. G. Tammann and K. Kollmann found that the e.m.f. of the cell, $\text{HgCo}_m : 2N\text{-CoSO}_4 : \text{HgCl}$, Hg falls at first rapidly, and after a few hours furnishes an e.m.f. corresponding with that of the saturated amalgam. J. Schumann observed that the liquid amalgam is less magnetic the more mercury it contains. J. Schumann, and A. A. Damour said that the amalgam is a dull silver-white colour, and is attracted by a magnet. H. Nagaoka studied the magnetic properties of the amalgam, and G. Tammann and W. Oelsen found that for an amalgam with 0.062 per cent. cobalt, the sp. magnetization is 0.311 gauss. A. A. Damour said that when cobalt amalgam is exposed to air, it becomes covered with a black powder of oxidized cobalt; but J. Schumann found the dark-coloured, hard crystals are not changed by exposure to air, and although the liquid amalgam is stable out of contact with air, it decomposes on exposure to air for 24 hrs. into a black powder of oxidized cobalt, and mercury. H. Nagaoka said that an amalgam with 5 per cent. of cobalt oxidizes readily in air, but it is protected from oxidation by a covering layer of boiled linseed oil. L. Paraskovich, and R. Erban and L. Paraskovich observed very little oxidation when amalgams with 0.2 to 0.5 per cent. of cobalt are exposed to air for a year. C. F. Schönbein found that when cobalt amalgam is shaken with water, or, better, with dil. sulphuric acid, some hydrogen dioxide is formed. J. Schumann observed that the amalgam is slowly decomposed by water, and it is insoluble in mercury. H. Moissan found that water without air forms cobaltous hydroxide, and with air a black, higher oxide. A. S. Russell and co-workers studied the order of removal of the metals from amalgams by oxidizing agents—ferric sulphate, potassium permanganate, and uranyl sulphate—and obtained the order Zn, Mn, Cu, Cr, Fe, Mo, Co, Hg, Ni, and W. M. Rabinovich and P. B. Zygotinsky found that cobalt is dispersed in mercury above the solubility limit to form a colloidal soln. G. Michaud reported a **cobalt-ammonium-mercury alloy**; and J. Schumann, a **cobalt-zinc-mercury alloy**.

I. Fetchenko-Tschopivsky⁷ studied the **cobalt-boron alloys** produced by cementation. C. Margot prepared **aluminium-cobalt alloys**, with 75 to 80 per cent. of cobalt, by melting a mixture of the component metals at a bright red-heat. The alloys were crystalline, brittle, and of the hardness of steel. They disintegrated after some days into a violet powder. Some alloys were also prepared by L. Guillet, S. Daniels, W. Pruszkowsky, H. Bohner, and N. Parravano and P. Agostini. H. Schirmeister said that the crucibles employed for making the alloys should be free from sulphur and carbon, since these substances make the alloys worthless.

A. G. C. Gwyer measured the f.p. of the alloys, and the curves, Fig. 38, have a maximum at 1628° and 68.5 per cent. of cobalt, corresponding with **cobalt aluminide**, CoAl ; and two breaks at 1165° and 38 per cent. of cobalt, and at 940° and 20 per cent. of cobalt. There is a minimum in the curve at 1375° and 90.5 per cent. of cobalt. There are two series of solid soln. containing respectively 68.5 to 80 per cent. and 90.5 to 100 per cent. of cobalt. The alloys with 82 to 90 per cent. of cobalt do not become homogeneous when heated for 3 hrs. at 1250° to 1270° . At 1165° , the cobalt monoaluminide reacts with the fused mass to form **cobalt hemipentaluminide**, Co_2Al_5 ; and at 940° to form **cobalt tritridecaluminide**, $\text{Co}_3\text{Al}_{13}$. W. L. Fink and H. R. Freche found crystals of **cobalt hemiennealuminide**, Co_2Al_9 . The hypoeutectic liquidus is a straight line extending from the f.p. of aluminium to the eutectic. Less than 0.02 per cent. of cobalt dissolves in solid aluminium at 655° . The intersection of the hypereutectic liquidus with the eutectic horizontal occurs with 1 per cent. of cobalt. The diagram was also studied by L. Guillet, who supposed that the compounds Co_8Al , Co_4Al , Co_2Al , CoAl_2 , and CoAl_4 can exist. S. Daniels said that the first eutectic lies between 0.40 and 0.94 per cent. of cobalt. The subject was investigated by W. L. Fink and H. R. Freche, who found that the solid solubility of cobalt in aluminium at 655° is less than 0.02 per cent.

O. Brunck obtained the 3 : 13-compound in parallel lamellæ which, when etched, form feathery crystals. A. J. Bradley, and A. Westgren discussed the structure of the cobalt aluminides. H. Schirmeister observed that alloys with 9 to 12 per cent. of cobalt had the best mechanical properties, although the tensile strength was very little greater than that of aluminium. Thus, the tensile strength in kgrms. per sq. mm., the percentage elongation, and Brinell's hardness of :

Cobalt	0	0.6	1.6	3.5	5.5	7.5	9.5	12.0 per cent.
Tensile strength	10.5	10.5	12.0	12.9	15.5	16.6	16.5	18.5
Elongation	34	35	28	21	18	14	11	6
Hardness	29	32	—	47	—	50	51	61

C. Margot said that alloys with 75 to 80 per cent. of cobalt are brittle, and as hard as hardened steel; and L. Guillet, that the sp. gr. of alloys with 5.4, 18.6, and 47.7 per cent. of aluminium have the sp. gr. 7.65, 5.87, and 4.15 respectively when the calculated values are 7.52, 5.93, and 4.05. W. Biltz and W. Holverscheit gave for the sp. gr. of CoAl , 6.03 at $25^{\circ}/4^{\circ}$, and the mol. vol. 14.3; and for Co_2Al_5 , the sp. gr. 4.19 at $25^{\circ}/4^{\circ}$, and the mol. vol. 60.4; they gave for the heat of formation, 32 Cals. for CoAl , and 86 Cals. for Co_2Al_5 . A. G. C. Gwyer gave 1628° for the m.p. of CoAl ; and found that Co_2Al_5 has a transformation point at 1100° , and at 1615° decomposes into CoAl , and a melt; whilst at 940° , $\text{Co}_3\text{Al}_{13}$ decomposes into Co_2Al_5 , and a melt. G. Tammann and K. Dahl said that the plastic deformation of $\text{Co}_3\text{Al}_{13}$ begins at 800° . W. Borchers and K. Schirmeister improved the mechanical properties of these alloys by the addition of up to about 1.2 per cent. of tungsten or molybdenum. E. Morlet examined the effect of cobalt on the hardness of the copper aluminium alloys. According to A. G. C. Gwyer, only alloys with over 68.5 per cent. of cobalt are magnetic, and the temp. at which the magnetism disappears on heating is progressively lowered by aluminium, as indicated by the dotted line in Fig. 38. A. von Zeerleder studied the action of acids on the alloys. S. F. Herman and F. T. Sisco, and W. W. Stiefler studied the magnetic properties of some alloys. E. Morlet studied some **copper-aluminium-cobalt alloys**.

FIG. 38.—Freezing-points of the Aluminium-Cobalt Alloys.

K. Lewkonja prepared some **cobalt-thallium alloys**, but found that the two elements are only slightly miscible in the liquid and solid states. There is no evidence of the formation of definite compounds. The f.p. of thallium is lowered 4° by 2.5 per cent. of cobalt, and 6° by 2.87 per cent., and the transformation temp. is lowered 7° or 8° . Just over the m.p. of thallium only 2.5 to 3 per cent. of cobalt is dissolved, and in molten cobalt, only 2.87 per cent. of thallium dissolves; the remainder distils off.

M. Dubowicky, R. Walter, C. L. Wilson and co-workers, and A. M. Portevin studied the cobalt-silicon alloys, and the cementation of cobalt by silicon. B. Egeberg prepared **cobalt-titanium alloys** by the aluminothermic process, and found that the solubility of titanium with cobalt is about 3.5 per cent. titanium, and that the eutectic has 19 per cent. titanium. The tensile strength attains a maximum with 4.5 per cent. of titanium and 70 kgrms. per sq. mm.; Brinell's hardness rises steadily to 484 at 21.5 per cent. titanium. The thermal, electric, and magnetic properties were also examined. The resistance of the alloys to 5 per cent. nitric acid decreased almost to zero with 12 per cent. of titanium—6.40, 13. M. G. Corson, and C. W. Wilson and co-workers studied the **copper-cobalt-silicon alloys**. C. A. Winkler, A. J. Kieser, and E. Vigouroux studied the ternary system involving **silicon-aluminium-cobalt alloys**. A. Stavenhagen and E. Schuchard⁸ obtained titanium-cobalt alloys by the thermite process. B. Egeberg made alloys with up to 20 per cent. of titanium and 2 to 3 per cent. of aluminium by the aluminothermite process. Alloys with 10 per cent. of titanium are coloured like cobalt, and those with higher proportions are silver-white. The hardness increases as the proportion of titanium rises from 0.5 to 11.0 per cent. The tensile strength increases rapidly with the titanium content up to a maximum of 70 kgrms. per sq. mm. with 5 to 6 per cent. of titanium, and an elongation of 5 per cent. The alloys with the greatest tensile strength have the finest grain. The mean coeff. of thermal expansion between 20° and 200° changes irregularly with composition between 0.041017 and 0.041112. The magnetic induction increases with increasing proportions of titanium; the remanence is greater with alloys having a heterogeneous texture than those with solid soln. The rate of dissolution of polished samples in 25 per cent. sulphuric acid at 20° to 97° , increases with

increasing proportions of titanium; and with 5 per cent. nitric acid at 97° , the rate of dissolution decreases. A soln. of 5 per cent. nitric acid, and 2 per cent. sodium chloride at 97° , attacks alloys with 2.31 and 4.67 per cent. of titanium at about the same rate, but alloys with 6.58 and 10.86 per cent. of titanium are attacked more quickly.

A. F. Gehlen prepared a violet, ductile **cobalt-tin alloy**. F. Ducelliez also obtained alloys of cobalt and tin by melting tin with powdered cobalt in a magnesia crucible in an atm. of hydrogen. Q. Marino obtained alloys by electrodeposition from soln. of the cyanides of the component salts along with alkali borotartarate and alkali or ammonium formate. F. Ducelliez said that alloys with 0 to 57.65 per cent. of tin contained as solid phases cobalt and **cobalt tritadistannide**, Co_3Sn_2 ; alloys with 57.65 and 66.76 per cent. of tin contain Co_3Sn_2 and **cobalt stannide**, CoSn ; and alloys with 66.76, 85, and up to 100 per cent. of tin contain the monostannide and tin. K. Lewkonja

FIG. 39.—Freezing-point Curves of Cobalt-Tin Alloys.

obtained the f.p. curves shown in Fig. 39. The two elements are miscible in all proportions in the liquid state. In the solid state, the maximum amount of tin dissolved by cobalt is 3.5 per cent. The first eutectic is at about 1088° , and

the second eutectic at 229° or 230°. The f.p. curves show the existence of **cobalt hemistannide**, Co_2Sn , melting at 1151°; and of cobalt stannide, CoSn , which melts with decomposition at 943° or 950°. The monostannide undergoes a polymorphic change at about 536°. Alloys with 20 to 45 per cent. of tin have the same dark eutectic as those with less than 35 per cent. of tin, but in alloys with 35 per cent. of tin, the crystals of the hemistannide appear. Alloys with 50 per cent. of tin are cracked and fissured, and contain rounded polyhedra of the hemistannide with very little eutectic. Alloys with 50 to 85 per cent. of tin show the presence of the dark monostannide; and alloys with over 85 per cent. of tin show the primary separation of large needles of the monostannide surrounded by a eutectic of tin and the monostannide. S. F. Schemtschuschny and S. W. Belynsky confirmed these results and said that the maximum on the f.p. curve occurs at 1171°, and there is a transition point at 927°, whilst above 515°, the monostannide separates out in α -crystals, and below in β -crystals. The eutectics were stated to occur at 229° and 79.5 at. per cent. of cobalt, and at 1112° with 1 at. per cent. of cobalt. The alloys were also studied by N. S. Konstantinoff. A. S. Russell and co-workers studied the system in mercury soln. G. Tammann and A. Rohmann found the heat capacity, c_{100} cal. per mol, for Co_2Sn , to be :

	-200° to -100°	-100° to 0°	0° to 100°	100° to 200°
c_{100}	1561.82	1739.30	1897.85	1968.85

P. Schübel gave for the true sp. ht., c , of Co_2Sn :

	100°	200°	300°	400°	500°	600°
c	0.0824	0.0876	0.0900	0.0926	0.0944	0.0962

and H. Schimpff gave $c=0.077873+0.04728544(\theta-17)-0.063033(\theta-17)^2$, or for the true sp. ht., c , and the at. ht., C :

	-150°	-100°	-50°	0°	50°	100°
c	0.0572	0.0652	0.0716	0.0765	0.0800	—
C	13.30	15.29	—	18.04	—	19.48

According to F. Ducelliez, when the alloys with 80.89 to 92.91 per cent. of tin are powdered, boiled with 25 per cent. nitric acid, levigated to remove metastannic acid, fused with potassium hydroxide and washed successively with water, alcohol, and ether, the monostannide remains. This compound can be formed by heating a mixture of atomic proportions of the two elements in an atm. of hydrogen. Combination occurs with incandescence; the product has a sp. gr. of 8.950 at 0°. The alloy is brittle at ordinary temp., and, according to G. Tammann and K. Dahl, plastic deformation begins at about 800°. A. Koch studied the potential of the alloy in a Daniell cell. F. Ducelliez, K. Lewkonja, and S. F. Schemtschuschny and S. W. Belynsky found that the monostannide is not ferromagnetic at room temp. G. Tammann and A. Koch found that the alloy becomes matte and darkens in colour when exposed to air for 10 to 20 minutes. F. Ducelliez noted that at a red-heat, the monostannide is attacked by chlorine, oxygen, and sulphur vapour; it is completely dissolved by hydrochloric or sulphuric acid, but is not attacked by boiling, dil. nitric acid, and only slowly by conc. nitric acid. G. Tammann and co-workers observed that at 18°, the monostannide is attacked, with a feeble evolution of gas, by $N\text{-H}_2\text{SO}_4$, and $N\text{-HCl}$. F. Ducelliez noted that fused alkali hydroxides, carbonates, nitrates, or chlorates attack the monostannide slowly. G. Tammann and A. Koch found that the monostannide precipitates copper, silver, and mercury from soln. of salts of these metals.

F. Ducelliez's tritadistannide evidently corresponds with K. Lewkonja's hemistannide. This compound can be isolated by treating the alloys, with 8.76 to 57.25 per cent. of tin, with 15 per cent. nitric acid followed by potassium hydroxide soln. The alloys behave like mixtures of cobalt and the tritadistannide, and their fragility, and the proportion of contained compound increase with the percentage of tin. There is no evidence of a cobalt tritastannide. The tritadistannide appears

as a powder having no well-characterized, crystalline form. Its sp. gr. is 8.86, and, like all the alloys containing it, it is magnetic. Its chemical properties resemble those of the monostannide, but it is less readily attacked by hydrochloric acid, and more easily attacked by nitric acid than is the case with the monostannide.

F. Ducelliez observed that the alloy with 80.89 per cent. of tin is grey and brittle; that with 89.28 per cent. of tin has a reticulated surface and can be cut; that with 92.91 per cent. of tin has the appearance and malleability of tin. F. Ducelliez observed that the electrode potentials of the alloys in $N\text{-CoSO}_4$ correspond with the existence of the monostannide. N. A. Puschin observed that the e.m.f. in millivolts of the $\text{Sn} : N\text{-H}_2\text{SO}_4 : \text{SnCo}_n$ and the $\text{Sn} : N\text{-KOH} : \text{SnCo}_n$ cells are respectively :

n	.	.	20	40	45	49.6	52	53.1	60	80	100
$N\text{-H}_2\text{SO}_4$.	.	8	4	29	114	200	214	294	179	142
$N\text{-KOH}$.	.	6	17	31	46	435	405	345	280	360

There is a break in the curve with 50 at. per cent. of cobalt corresponding with the monostannide. There is no sign of F. Ducelliez's tritastannide. G. Tammann and A. Koch studied the e.m.f. of the alloys. S. F. Schemtschuschny and S. W. Belynsky observed that the hemistannide is magnetic whilst the monostannide is non-magnetic in both the α - and β -forms. F. Ducelliez, and K. Lewkonja also observed that only alloys with over 50 per cent. of cobalt are magnetic at ordinary temp., and the intensity of the magnetization increases as the proportion of cobalt increases. The transformation temp. of alloys with from 2.5 to 50 per cent. of tin is 985° . O. Barth observed that alloys with only small proportions of one or other of the metals are more readily attacked by acids than is the case with the pure metals. An alloy with 60 per cent. of tin is highly resistant to acids, but is brittle and unworkable. E. A. Drysdale studied the corrodibility of these alloys. O. Barth examined some alloys containing carbon.

According to F. Ducelliez,⁹ homogeneous **lead-cobalt alloys** can be obtained by subjecting mixtures of the two metals to hydraulic pressure, and then heating

FIG. 40.—Freezing-point Curves of the Cobalt-Lead Alloys.

the mixture to 1400° in magnesia crucibles in an atm. of hydrogen. The products with 22.8 to 95.1 per cent. of cobalt behaved as mixtures, and no evidence of the formation of definite chemical compounds was observed. K. Lewkonja obtained the f.p. curves indicated in Fig. 40. The two elements are partially miscible in the liquid state. Molten alloys with over 3 per cent. or more than 99 per cent. of cobalt cannot be obtained. In the solid state, neither compounds nor solid soln. are formed. W. Oelsen found that lead dissolved 11×10^{-4} to 21×10^{-4} per cent. of cobalt. W. Seith and A. Keil, and K. Fischbeck discussed the diffusion of cobalt in lead; and W. Guertler and H. Schack, alloys with sulphur.

E. Haynes,¹⁰ and F. Wever and U. Haschimoto prepared **chromium-cobalt alloys**; H. C. Pfeffer and H. C. Pierce obtained the alloys electrolytically; and K. Lewkonja studied the f.p. curves. Cobalt and chromium are miscible in all proportions in the liquid and solid states. The minimum temp. at which crystallization commences is 1320° when the fused mass has 47 per cent. of chromium. Alloys with 30 to 100 per cent. of chromium undergo a change in structure at about 1226° , for the crystals of the homogeneous solid soln. primarily formed in the cooling process are transformed into two different kinds of crystals, which are readily distinguished when a polished surface of the metal is etched by electrolysis. The modifications of F. Wever and co-workers, and R. Ruer and co-workers are summarized in Fig. 41; the subject was discussed by A. Michel and P. Benazet,

and J. A. M. van Liempt. F. Wever and U. Haschimoto found the crystals of **cobalt monochromide**, CoCr , to be probably tetragonal, with 8 mols. in the elementary cell, and the parameters $a=5.33 \text{ \AA.}$, and $c=7.20 \text{ \AA.}$ The equilibrium conditions of this compound and of **cobalt hemifrichromide**, Co_2Cr_3 , are indicated in Fig. 41. F. Wever and U. Haschimoto used ammonium persulphate as an etching soln. for the alloys. The hardness attains a maximum with about 70 per cent. of chromium; the tensile strength rises to 90 kgrms. per sq. mm. with 30 per cent. of chromium. The mechanical properties were also studied by E. Haynes, H. T. Kalms, and G. Tammann. W. H. Souder and P. Hindert gave for the mean coeff. of linear expansion of an alloy with 20 per cent. of chromium, 0.04141 between 20° and 100° ; 0.04052 between 20° and 300° ; and 0.04161 between 20° and 600° . A. W. Smith studied the thermal conductivity. Observations on the magnetic properties were made by K. Honda, F. Wever and co-workers, and R. Ruer and co-workers. K. Lewkonja found that at room temp., alloys with up to 25 per cent. of chromium are magnetizable, and alloys with 15 per cent. of chromium possess the greatest magnetic intensity :

FIG. 41.—The Freezing-point Curves of Chromium-Cobalt Alloys.

Chromium	0	10	15	20	25 per cent.
Magnetic intensity . .	15.70	22.50	33.80	5.28	0.20 (relative)
Loss of magnetism . .	1056°	686°	300°	—	—

E. Haynes found that alloys with 10 to 60 per cent. of chromium, and free from sulphur, remain bright in the atm. of a laboratory, and an alloy with 25 per cent. of chromium at about 500° became straw-yellow, and at a higher temp., bronze-yellow, purple, blue, and bluish-black. G. Tammann and W. Köster observed that alloys with 20 to 40 per cent. of chromium, when heated between 500° and 800° for 1 hr., acquire a film of oxide at a rate in accord with an exponential law. F. Wever and U. Haschimoto found that the velocity of oxidation at 700° to 1000° decreases with increasing proportions of chromium; at 1100° to 1200° , an alloy with 30 per cent. of chromium holds the oxide film tenaciously, and is less attacked than alloys with 20 to 40 per cent. of chromium which in turn readily give a scaling oxide. W. Guertler and T. Liepus observed that the 1:1-cobalt-chromium alloy was attacked within 8 hrs. by 10 and 50 per cent. nitric acid; 10 and 36 per cent. hydrochloric acid; aqua regia; 10 per cent. sulphuric acid, and 20 per cent. sulphuric acid sat. with sodium sulphate; carbon dioxide and air; acetic, citric, and tartaric acids; and 10, 50, and 70 per cent. aq. ammonia. A 10 per cent. soln. of sodium hydroxide did not attack the alloy in 48 hrs., but a 50 per cent. soln. did so in 8 hrs., and a soln. with hydrogen dioxide did not attack the alloy in 48 hrs. A 10 per cent. soln. of sodium sulphide did not attack the alloy in 48 hrs., but a 50 per cent. soln. did so in 8 hrs., and a soln. with 4 per cent. of sodium sulphide and 8 per cent. of alkali did so in 8 hrs. Chlorine water did not attack the alloy in 8 hrs., whilst sea-water, sea-water and air, rain-water and air, and a soln. of magnesium chloride did not do so in 48 hrs. A 1:500-soln. of mercuric chloride is decomposed by the alloy. W. Rohn found that with un-annealed and annealed samples of a Co:Cr (90:10)-alloy, the loss in grams per sq. dm. with 10 per cent. nitric acid was respectively 12.9 and 9.5 in 24 hrs. cold, and 15 and 17.3 in 1 hr. hot; 10 per cent. sulphuric acid, respectively 0.027 and 0.012 in 24 hrs. cold, and 2.7 and 2.4 in 1 hr. hot; and 10 per cent. hydrochloric

acid, respectively 0.13 and 0.06 in 24 hrs. cold, and 1.5 and 1.2 in 1 hr. hot. G. Masing studied the age-hardening of **copper-silicon-chromium-cobalt alloys**. W. Köster studied the **chromium-cobalt-iron alloys**.

C. L. Sargent¹¹ prepared **cobalt-molybdenum alloys** by heating mixtures of the oxides of these metals with sugar charcoal in an electric furnace; and U. Raydt

FIG. 42.—Freezing-point Curves of Cobalt-Molybdenum Alloys.

and G. Tammann obtained alloys with up to 65 per cent. of molybdenum by heating in magnesia vessels, at 1800°, mixtures of the two elements; mixtures with more molybdenum are not completely fused at that temp. Alloys richer in molybdenum can be prepared by the thermite process, but then they always contain aluminium. The f.p. curves of these alloys, shown in Fig. 42, are due to U. Raydt and G. Tammann, and W. Köster and W. Tonn. The f.p. curve has a eutectic at 1335° and about 38 per cent. molybdenum. Solid soln. are formed with up to 28 per cent. of molybdenum. The curve rises from the eutectic and suffers a break at 1484° corresponding with **cobalt molybdiide**, CoMo , which does not form solid soln. There is no indication of the formation of any other compound. The compound is non-magnetic, but the solid soln. rich in cobalt is magnetic. The temp. of the reversible transformation falls from 1143° for cobalt, to about 760° for the sat. solid soln. The molybdiide crystallizes in long needles, and the free molybdenum forms rounded crystallites. The curve AB represents the magnetic transformation of the γ -solid soln.; and CD , of the ϵ -solid soln. T. Takei added the dotted lines to Fig. 42, to accord with his examination of the X-radiograms. These indicate the existence of alloys rich in cobalt, γ , with a face-centred, cubic lattice; alloys rich in cobalt, with a hexagonal lattice, with indications of the molybdiide, CoMo , ϵ , of **cobalt hemitrimolybdiide**, Co_2Mo_3 , η , and of the solid soln., δ , containing 2 per cent. of cobalt. R. Vogel observed that the solid soln. with 20 per cent. molybdenum exhibit deformation twinning. V. Adelsköld and co-workers studied the system Co-Mo-C , but observed no formation of a complex carbide. W. Köster and W. Tonn studied the magnetic properties of the alloys.

F. Wever and U. Haschimoto observed the action of dil. nitric acid, and of citric acid; and E. Haynes, the action of nitric, hydrochloric, and sulphuric acid. E. Haynes found that alkali-lye does not attack the 25 per cent. alloy during 1 hour's boiling; F. Wever and U. Haschimoto, and W. Borchers examined the influence of additions of copper, aluminium, silicon, molybdenum, tungsten, manganese, iron, and nickel on the acid-resistance of the alloys. W. Guertler and T. Liepus found that a 70:30-alloy of cobalt and molybdenum was attacked in 8 hrs. by a 10 per cent. soln. of sulphuric acid, and by 20 per cent. sulphuric acid sat. with sodium sulphate; by carbon dioxide and air; acetic acid; citric acid; tartaric acid; by 10 and 50 per cent. soln. of sodium hydroxide; 10 and 50 per cent. aq. ammonia; 10 per cent. sodium sulphide; chlorine water; sea-water; sea-water plus air; rain-water plus air; and a soln. of magnesium chloride. No attack was observed after 24 hrs. in contact with 10 and 50 per cent. nitric acid; 10 and 35 per cent. hydrochloric acid, or with aqua regia. No action was observed after 8 hrs' contact with soda-lye and hydrogen dioxide, or with a mixture of 4 per cent. sodium sulphide and 8 per cent. alkali. K. Kreitz studied the action of nitric acid.

C. L. Sargent studied the alloys with carbon. L. F. Dreiholz studied the ternary system; **copper-molybdenum-cobalt alloys**; and W. Guertler made

some observations on the technical applications of these alloys. W. Guertler and T. Liepus studied the action of various reagents on a copper-molybdenum-cobalt alloy. H. Schirmeister prepared a few **aluminium-molybdenum-cobalt alloys**, and found that they behaved like those with tungsten in place of molybdenum (*q.v.*). E. Haynes also investigated some **chromium-molybdenum-cobalt alloys**. F. Stäblein studied their magnetic properties; and W. Guertler and T. Liepus examined the effect of various reagents on these alloys.

In 1860, F. A. Bernoulli¹² said that **cobalt-tungsten alloys** can be prepared only by the simultaneous reduction of the two metals. H. List said that the metals do not form true alloys. Alloys were also made by N. Drebes by reducing a mixture of tungsten and cobalt oxides with aluminium. A. Stavenhagen and E. Schuchard also obtained the alloys by the thermite process. C. L. Sargent, D. Kremer, F. Stein, K. Kreitz, and W. Geiss and J. A. M. van Liempt prepared the alloys by heating mixtures of the oxides with sugar charcoal in an electric furnace.

C. Agte and co-workers found that the solubility of cobalt in tungsten is near 10 at. per cent.; and of tungsten in cobalt, 8 at. per cent. Alloys with between 52 and 63 at. per cent. have an intermediate crystalline phase which on the tungsten side is non-magnetic, and they become magnetic as the proportion of cobalt increases. K. Kreitz's, W. P. Sykes', and W. Köster and W. Tonn's observations on the f.p. of the alloys are summarized in Fig. 43. There is evidence of the formation of two compounds: one is thought to be **cobalt hexitangstide**, Co_6W , melting at about 1500° ; and the other **cobalt tungstide**, CoW , melting at about 1650° . Alloys with 0 to 40 per cent. of tungsten consist of a series of solid soln.; and those with 40 to 70 per cent., of a mixture of the eutectic and solid soln.; or of eutectic and the monotungstide, according as the alloy contains less or more than 45 per cent. of tungsten. The eutectic is at 1400° and 44.5 per cent. of tungsten. AB represents the curve of magnetic transformation of the γ -solid soln.; and CD , of the α -solid soln. C. Agte and co-workers also studied the system; and V. Adelsköld and co-workers observed that in the presence of carbon, the complex **cobalt tungsten tritacarbide**, $\text{Co}_3\text{W}_3\text{C}$, is formed. C. L. Sargent found the sp. gr. of alloys with 48.26, and 70.10 per cent. of cobalt to be respectively 10.96, and 8.92. According to K. Kreitz, the addition of tungsten to cobalt rapidly increases the brittleness, and Brinell's hardness of the alloys, thus:

Tungsten	0	0.95	2.15	3.02	4.64	9.7	24.15 per cent.
Hardness	185	188	196	202	214	282	288

N. Drebes found that the alloys with 75 to 95 per cent. tungsten are very hard. By annealing over 1200° , K. Kreitz found it possible to roll the alloys into thin plates. The sp. electrical resistance and conductivity respectively in ohms or mhos per cm. cube, for alloys carrying about 0.6 per cent. of iron, are:

Tungsten	0	0.95	2.15	3.02	4.64	9.7	12.1	24.15 per cent.
Ohms $\times 10^4$	0.0980	0.0375	0.1905	0.2270	0.3130	0.4450	0.8060	0.7145
Mhos $\times 10^{-4}$	11.03	7.27	5.25	4.30	5.32	2.25	1.98	1.40

W. Geiss and J. A. M. van Liempt found that the concentration-temp. coeff. curve, Fig. 44, between -183° and 20° shows nothing of the existence of a continuous series of solid soln. There are probably two or more kinds of solid soln., and also,

FIG. 43.—Freezing-point Curves of the Cobalt-Tungsten Alloys.

possibly compounds. W. Köster and W. Tonn studied the magnetic properties of the alloys; and C. Agte and co-workers found that the relative magnetization, I , of the alloys increases as the atomic percentage of cobalt increases:

Co . . .	0	55	57	65	72	90	95	100
I . . .	0	0	0.47	2.8	10.2	44.0	61.1	100

F. Stein found that alloys with up to 3 per cent. of tungsten are more readily attacked by sulphuric acid than is cobalt, but with increasing proportions of tungsten, the resistance is greater. Thus, representing the corrosion in mgrms. per sq. mm. per hour:

Tungsten . . .	0	0.95	2.15	3.025	4.64	5.02	9.75	12.01 per cent.
Corrosion {	20° . . .	0.065	0.025	0.072	0.00135	0.0012	—	0.0361
	98° . . .	0.0154	0.0176	0.84	1.203	1.055	1.09	0.098

The solubility in mgrms. per sq. mm. per hour in a soln. of 2 per cent. sodium chloride mixed with 5 per cent. nitric acid at 98°, is for alloys with 0, 3.025, 5.02, and 12.01 per cent. of tungsten, respectively 0.0482, 0.334, 0.406, and 0.736.

J. L. Gregg and C. W. Küttner, L. L. Wyman and F. C. Kelley, S. L. Hoyt, and K. Schröter studied the alloys with carbon. H. Schirmeister found that in the **aluminium-tungsten-cobalt alloys**, the addition of a small proportion of tungsten raised the tensile strength of the aluminium-cobalt alloys, and made the fracture finer. Larger proportions of tungsten were injurious. The best proportions were 0.8 to 1.2 per cent. of tungsten. The hardness is proportional to the amount of cobalt in the alloy. The alloys are

easy to work, take a good polish, and resist the action of the air. The sp. gr. is 2.8 to 2.9.

E. Haynes prepared some **chromium-tungsten-cobalt alloys**. O. Rumschöttel found that tungsten separated out in the freezing of alloys made by adding an alloy

of cobalt and tungsten to one of zinc and copper. Alloys were also made by L. Guillet and H. Godfroid, A. Hofmann, G. L. Kronfeld, E. Schiffer, and E. H. Schulz and co-workers. W. Oertel and E. Pakulla studied the f.p. of the alloys. The structure of the alloys was studied by C. W. Drescher, T. Spooner, H. Brösamlen, W. H. Losee, S. B. Wright, H. J. French and H. K. Herschmann, L. Guillet and H. Godfroid, A. V. Harris, A. Hofmann, K. Löbbecke, W. Oertel and E. Pakulla, and E. H. Schulz and co-workers. W. Köster's observations on the nature of the solid soln. are summarized in Fig. 45. C. W. Drury found that a stellite with a low proportion of tungsten had a face-centred, cubic lattice with

FIG. 44.—Temperature Coefficient of the Electrical Resistance of the Cobalt-Tungsten Alloys.

FIG. 45.—Phases in the Ternary System: Co-Cr-W.

$\alpha = 3.554$ to 3.585 A. W. Oertel and E. Pakulla studied the mechanical properties of these alloys, and of alloys with molybdenum in place of tungsten. E. Haynes' alloy, called *stellite*, is usually composed of chromium, cobalt, and tungsten, and it may be modified by the addition of iron, or by the substitution of some molybdenum for tungsten, or nickel for cobalt—e.g., (i) soft malleable stellite has Co, 80; Cr, 20 per cent.; (ii) hard, malleable stellite has Co, 55; Cr, 40; W, 3; and C, 2 per cent.; and another stellite (iii) has Co, 55; Cr, 35; and W, 10 per cent. Other alloys of a similar character have the trade-names *celsite*, *cædite*, *volomit*, *thoran*, *akrit*, *widia*, etc. K. Löbbecke said that the average composition of the stellite alloys is Co, 55;

Cr, 28; W, 15; C, 2.5 with small proportions of impurities, chiefly iron. The hardness increases with increasing chromium and decreasing cobalt-content, but tungsten has very little influence on the hardness. An increase in the proportion of carbon causes at first an increase in hardness followed by a fall to a constant value owing to the formation of graphite. The resistance to wear increases generally with decreasing cobalt-content; the chromium and tungsten have very little influence. The subject was studied by G. S. Armstrong, F. Bauerfeld, C. W. Drury, L. Guillet, E. Guillet and H. Godfroid, W. H. Losee, M. Märkle, S. Malowan, A. Merz and W. Schütz, W. Oertel and E. Pakulla, F. Rapatz, E. H. Schulz and co-workers, and R. Walter. W. H. Souder and P. Hidnert found for the coeff. of thermal expansion, α , of the three samples of stellite just indicated:

	20°-100°	100°-200°	200°-300°	300°-400°	400°-500°	500°-600°	20°-600°
$\alpha \times 10^6$ { i	14.1	15.1	16.2	15.9	16.0	18.9	16.1
ii	13.4	15.2	16.0	16.3	17.5	20.2	16.5
iii	11.0	12.3	13.6	13.8	13.3	16.9	13.6

E. H. Schulz and W. Jenge observed that the alloy melts near 1250°. W. W. Coblenz found the reflecting power, R , for wave-lengths λ in $\mu=0.001$ mm., to be:

λ	0.45	0.50	0.70	0.90	1.00	1.50	2.00	3.00	4.00 μ
R	63.5	65.8	71.8	73.5	74.0	75.3	76.8	80.0	82.8 per cent.

I. C. Gardner, E. O. Hulburt, P. R. Gleason, W. W. Coblenz and co-workers, and G. G. Abbot and co-workers, also measured the reflecting power of stellite. E. Haynes, and W. Oertel and E. Pakulla observed that a blue, protective film was formed when the alloy was exposed to 1000°. The alloy is attacked by hydrofluoric, hydrochloric, and sulphuric acids and by molten alkalis; but it is scarcely affected by phosphoric, and organic acids, alkali-lye, and by soln. of ammonium and mercuric chlorides. E. Schiffer said that the powdered alloy dissolves slowly in aqua regia, bromine aqua regia, bromine and hydrochloric acid, and in a soln. of potassium chlorate in a mixture of hydrochloric and sulphuric acids. E. Deiss studied the action of hydrochloric acid, and molten sodium dioxide and carbonate. W. Oertel and E. Pakulla examined the action of aqua regia, hydrochloric, sulphuric, nitric, oxalic, and tannic acids, sea-water, potash-lye, and a sulphuric acid soln. of copper sulphate. E. Cremer and B. Fetkenheuer observed that the alloys are attacked by molten potassium hydrosulphate, or by a mixture of sodium carbonate and potassium carbonate and nitrate. J. G. Thompson and co-workers studied the action of soln. of urea and of ammonium carbamate. K. Löbbecke studied the corrodibility of the alloys in hydrochloric acid, and E. H. Schulz and W. Jenge found that the alloy begins to oxidize in air at about 1000°; and it is stable in contact with hydrofluoric and sulphurous acids, and a soln. of mercuric chloride. K. Löbbecke observed that the alloy most resistant to corrosion by hydrochloric or acetic acid is the Co:Cr:W:C=55:28:15:2.5 alloy indicated above. The resistance to corrosion is sensitive to the proportion of contained carbon. Observations on a similar alloy, *akrit*, with cobalt 38 per cent.; Cr, 30; W, 16; Ni, 10; Mo, 4; and C, 2 to 5, were made by E. H. Schulz, and C. W. Drescher. W. Oertel and E. Pakulla studied the **molybdenum-chromium-cobalt alloys**. A. Stavenhagen and E. Schuchard prepared **tungsten-molybdenum-chromium-cobalt alloys**, as well as **uranium-cobalt alloys**, by the thermite process. P. A. Heller obtained uranium-nickel alloys by fusing uranium carbide and nickel oxide in a carbon crucible in an arc furnace. The alloys contained 4.5 to 5 per cent. of carbon.

K. Hiege¹³ prepared **cobalt-manganese alloys**, and found that they form a continuous series of solid soln. with a flat minimum at about 30 per cent. of cobalt and 1150°, Fig. 46. The crystals are not homogeneous but become nearly so after the alloys have been annealed for 5 hrs. in magnesia at 1000°. The magnetic transformation curve falls rapidly from 1150° with increasing proportions of manganese. G. Tammann and E. Vaders studied the e.m.f. of the alloy, and

observed that the limit of the solid soln. has about 0.50 mol. Co. The subject was studied by J. A. M. van Liempt. E. Persson and E. Oehlman made observations

on the X-radiograms—*vide* manganese; B. Blumenthal and co-workers, on the structure of the alloys; and W. Köster and W. Schmidt, the relation between the lattice structure and ferromagnetism.

G. Tammann and E. Vaders observed that with hydrochloric acid, alloys with less than 39.6 per cent. of manganese develop no hydrogen, but with higher proportions, hydrogen is developed. G. Arrivaut found that soln. of ammonium chloride, or hydrofluoric, hydrochloric, sulphuric, or nitric acid dissolve alloys with 60 to 85 per cent. of manganese completely. Alcoholic soln. of acetic acid and ammonium acetate dissolve most of the man-

ganese, leaving a pyrophoric residue with about 5 per cent. of manganese. W. Guertler and T. Liepus found that the 1:1-cobalt-manganese alloy was attacked in 8 hrs. by 10 and 50 per cent. nitric acid; by 10 and 36 per cent. hydrochloric acid; aqua regia; 10 per cent. sulphuric acid, and 20 per cent. sulphuric acid sat. with sodium sulphate; carbon dioxide and air; acetic acid; tartaric acid; citric acid; 10 and 50 per cent. sodium hydroxide; sodium hydroxide and hydrogen dioxide; 10, 50, and 70 per cent. aq. ammonia; 10 and 50 per cent. sodium sulphide, and 4 per cent. sodium sulphide mixed with 8 per cent. alkali; chlorine water; sea-water; sea-water plus air; rain-water plus air; and magnesium chloride soln. It decomposed a 1:500-soln. of mercuric chloride. The action on the alloy Co : Mn : Mo = 40 : 50 : 10 by nitric acid, hydrochloric acid, aqua regia, citric acid and tartaric acid; soda-lye; sodium sulphide; sea-water; and magnesium chloride soln. was studied. W. Guertler and T. Liepus also examined **cobalt-manganese-molybdenum alloys**.

According to A. F. Gehlen,¹⁴ J. F. Hassenfratz, T. Fleitmann, P. Oberhoffer, C. J. B. Karsten, J. Percy, F. Toldt, J. Stodart and M. Faraday, J. L. F. Vogel, R. A. Hadfield, W. Pruszkowsky, and G. H. Billings, the **iron-cobalt alloys** can be readily formed. The alloy is malleable and weldable; it is not cold-short, but inclined to be red-short. R. A. Hadfield noted that cobalt raises the elasticity of iron. P. Berthier observed that the alloys of iron with cobalt closely resemble those with nickel. O. E. Erdmann, and A. Weiske observed that traces of cobalt occur in many commercial irons. C. F. Burgess and J. Aston found that alloys with up to 6 per cent. of cobalt can be forged without difficulty at the normal forging temp.; alloys with less than 6 per cent. of cobalt can be welded electrically; and all can be machined in the lathe. The electrolytic production of the alloys was discussed by G. Bruni and M. Amadori, H. J. Blikslager, S. Glasstone and J. C. Speakman, and H. W. Töppfer; and the electrometallurgy of the alloys, by F. Peters. The diffusion of cobalt in iron was studied by J. Laissus, and N. Ageeff and M. Zamotorin. A selection from W. van Drunen's results for the diffusion coeff., *D*, are as follow:

TABLE III.—THE DIFFUSION OF COBALT INTO IRON.

1250° (72 hrs.)			1300° (72 hrs.)			1350° (48 hrs.)			1400° (48 hrs.)		
Depth cm.	Cobalt %	<i>D</i> × 10 ⁸	Depth cm.	Cobalt %	<i>D</i> × 10 ⁸	Depth cm.	Cobalt %	<i>D</i> × 10 ⁸	Depth cm.	Cobalt %	<i>D</i> × 10 ⁸
0.00225	34.8	0.553	0.00250	41.5	0.146	0.00250	44.6	0.846	0.00125	45.7	0.334
0.00725	16.0	0.887	0.01360	13.0	0.229	0.01300	16.6	0.448	0.01050	25.1	0.480
0.01225	3.1	0.718	0.02450	0.8	0.169	0.01850	6.2	0.361	0.02250	4.1	0.418

FIG. 46. — The Freezing-point Curves of the Manganese-Cobalt Alloys.

The equilibrium diagram has been worked out by W. Guertler and G. Tammann. They found for the f.p. of mixtures on the heating and cooling curves :

Cobalt	0	5	13	30	50	60	80	100 per cent.
Heating	1485°	1440°	1430°	1435°	1435°	1425°	1430°	1435°
Cooling	1475°	1440°	1440°	1445°	1440°	1445°	1440°	1450°

Cobalt has very little influence on the m.p. of iron. Fig. 47 is due to R. Ruer and K. Kaneko. Iron has a transformation point at 1420° when δ -iron becomes γ -iron. This temp. is raised by the addition of cobalt. The f.p. curve has two branches one of which has a minimum at 1475° and 65 per cent. of cobalt. The two branches, which correspond with the f.p. of two series at solid soln., intersect at 1493° and 15.5 per cent. of cobalt. The thermal changes at lower temp. agree with the magnetic changes. The $\gamma \rightarrow \beta$, and the $\beta \rightarrow \alpha$ transformations coincide from 15 per cent. of cobalt onwards, and they increase with increasing cobalt. The transformation curve passes through a maximum at 980° and 45 per cent. of cobalt; and the eutectoidal point must lie somewhere between 70 and 75 per cent. of cobalt. The curve *hkl*, Fig. 47, represents the reversible transformation of the α -phase to the γ -phase; *rk*, the reversible magnetic transformation of the α -phase; and *on*, the curve of reversible transformation of the non-magnetic β -cobalt to the magnetic α -cobalt. The diagram was discussed by A. Kußmann and co-workers, J. A. M. van

FIGS. 47 and 48.—Equilibrium Diagram of the Cobalt-Iron Alloys.

Liempt, L. Grenet, and F. Wever. P. Weiss said that the magnetic transformation agrees with the existence of **cobalt diferride**, Fe_2Co . W. Guertler and G. Tammann said that the alloys rich in cobalt, i.e. those with 75 to 100 per cent. of cobalt, suffer the magnetic transformation at the same temp.; alloys with 60 to 75 per cent. of cobalt suffer a more gradual transformation, for there is an interval of about 100° between the heating and cooling curves; alloys with 5 to 60 per cent. cobalt show an undercooling effect of 20° to 30°; and the alloys rich in iron—i.e. with less than 5 per cent. cobalt—suffer transformation like iron at about 760°. With repeated heatings, the temp. at which magnetization vanishes, increases up to 820°; while the temp. at which magnetization returns, is about constant at 752°. H. Scott found that cobalt did not have a marked effect on the conversion of martensite to troostite. H. Masumoto's results for the equilibrium of the solid alloy are shown in Fig. 48. There is a transformation point for cobalt at 403°, and this corresponds with a region where the solid soln. of the γ -iron and cobalt forms a solid soln. of γ -iron in hexagonal cobalt. Both the A_4 - and A_3 -arrests are raised by the addition of cobalt. The effect of cobalt in the A_2 - and A_3 -arrests was found to be :

Fe	21.14	27.13	40.11	55.08	65.06	80.04	100 per cent.
Ac ₂	943°	908°	—	—	—	—	—
Ar ₂	932°	875°	—	—	—	—	—
Ac ₃	874°	863°	938°	981°	955°	920°	908°
Ar ₃	407°	833°	930°	970°	964°	927°	888°

A. Osawa found that in the case of the α -solid soln. of iron and cobalt the lattice-constant concentration curve is of the second degree.

Iron . . .	95	90	80	60	50	25	24 per cent.
<i>a</i> . . .	2.855	2.854	2.851	2.847	2.846	2.825	2.825 A.
Iron . . .	20	10	5	3	1.5	1.0	0.5 per cent.
<i>a</i> . . .	2.824	—	—	—	2.493	2.493	2.492 A.
<i>c</i> . . .	3.434	3.541	3.536	3.533	4.066	4.062	4.062 A.

The cobalt-carbon system, studied by G. Boecker, A. Schulze, W. C. Ellis, E. L. Reed, R. Vogel and W. Sundermann, L. Grenet, and by O. Ruff and F. Keilig, has been discussed in connection with the carbides—5. 39, 20. At 1700°, cobalt dissolves 3.9 per cent., and at the eutectic temp., 1300°, cobalt retains 0.82 per cent. of carbon in solid soln. The presence of a carbide in the eutectic cannot be proved; for the eutectic appears to contain only graphite and crystals of cobalt. J. O. Arnold and A. A. Read thought that they could demonstrate the existence of a cobalt cementite, CoC_3 , by the method of residual analysis. The negative heat of formation of this carbide, as determined by O. Ruff and co-workers, is not so great as to exclude the possibility of its existence in cobalt steels. J. O. Arnold and A. A. Read observed that cobalt has a smaller tendency than nickel to produce graphite; and

FIG. 49.—The Effect of Cobalt on the A_1 -arrest of 0.2 per cent. Carbon Steel.

O. Bauer and E. Piwowarsky observed with respect to cast iron that up to 2 per cent. of cobalt serves no useful purpose, but it has a tendency to retain carbon in the combined state. L. Guillet observed that steels with up to 40 per cent. of cobalt are all pearlitic even when they contain 0.80 per cent. of carbon. L. Dumas represented the effect of cobalt on the A_1 -transformation of a steel with 0.2 per cent. of carbon by Fig. 49. J. O. Arnold said that cobalt does not form a "true" steel having 100 per cent. pearlite. H. Sawamura, and F. Roll showed that cobalt favours the decomposition of the carbide in cast iron; Y. Umansky and E. Gordon, the lattice structure of the contained martensite; A. Michel and P. Bénazet, and E. Prétet studied the effect of cobalt on the tempering of the quenched alloy; and L. Grenet, the transformation of the alloys from one state to another.

According to M. R. Andrews, and Z. Nishiyama, the iron-cobalt alloys have a body-centred cubic lattice with up to about 70 at. per cent. of cobalt; and the effect of adding cobalt to iron is to reduce the grating space from $a=2.850$ A. for iron, to $a=2.827$ A. for an alloy with 66.7 per cent. of cobalt. The change is not linear. Alloys with 90 to 98 per cent. of cobalt are face-centred cubic with a from 3.550 A. to 3.540 A., and alloys with about 70 to 80 per cent. of cobalt have mixed lattices. Cobalt alone at room temp. has a close-packed, hexagonal space-lattice. Z. Nishiyama found the lattice constant, a , of alloys with 5, 10, 15, and 20 per cent. of cobalt, $a=2.867$ A., 2.867 A., 2.867 A., and 2.868 A. respectively. H. Perlitz discussed the distance apart of the atoms. Z. Nishiyama found for the sp. gr., at 13.4° to 13.8°, of alloys with 5, 10, 15, and 20 per cent. of cobalt, the respective values 7.8811, 7.9002, 7.9133, and 7.9411; W. Brown found that the sp. gr. and sp. vol. of steels with 0.25 per cent. carbon and 1.8 per cent. cobalt, were respectively 7.8117 and 0.12801, and with 0.52 per cent. carbon and 7.0 per cent. nickel, respectively 7.8326 and 0.12767. Hence, with up to 7 per cent. of cobalt, the sp. vol. decreases at the rate of 0.0001 c.c. for every per cent. of added cobalt. A. Osawa, A. Preuss, P. Dejean, and B. Simmersbach discussed this subject. L. Guillet found the following mechanical properties for cobalt steel with about 0.8 per cent. of carbon:

Cobalt	4.45	6.72	9.76	29.30 per cent.
Elastic limit	46.6	51.1	44.0	50.5 kgrms. per sq. mm.
Tensile strength	121.8	102.3	122.6	118.5 " " "
Elongation	6	7	5	6 per cent.
Reduction of area	10.6	14.6	6.8	11.5 " "
Brinell's hardness	248	241	248	241

L. Guillet added that the presence of cobalt slowly raises the tensile strength and elastic limit while diminishing the elongation and reduction of area. There is no sudden alteration in the mechanical properties, which are changed only gradually. Observations were also made by C. E. Guillaume, K. Honda, E. K. Smith and H. C. Aufderhaar, L. Guillet, K. Sasagawa, R. Scherer, I. Musatti and G. Calbiani, J. Stodart and M. Faraday, R. A. Hadfield, K. Taniguchi, and C. B. Browne. G. Tammann and V. Caglioti studied the recovery of the hardness after cold-working. L. Dumas' results with steel containing 0.2 per cent. of carbon are summarized in Fig. 50. The observations of J. O. Arnold and A. A. Read are as follows :

Carbon (combined)	0.64	0.62	0.84	0.93	0.72 per cent.
Cobalt	2.68	5.50	11.18	16.97	20.85 " "
Yield-point	45.3	51.1	50.5	58.8	62.0 kgrms. per sq. mm.
Tensile strength	75.0	75.8	108.8	116.8	110.5 " " "
Elongation	17.5	22.5	11.5	9.5	11.0 per cent.
Reduction of area	26.7	42.7	21.5	12.7	18.9 " "
Number impacts for fracture	242	233	158	174	123

FIG. 50.—The Mechanical Properties of 0.2 per cent. Carbon Steel.

FIG. 51.—Modulus of Elasticity and Rigidity of Iron-Cobalt Alloys.

H. T. Kalmus and K. B. Blake said that the Fe_2Co -alloy can be readily forged, and it then has twice the strength of purified iron ; mechanically the alloy is brittle, but when annealed, it has the same ultimate strength as purified iron. T. D. Yensen gave for purified iron, and the Fe_2Co -alloy, both melted in vacuo, as forged, gave the respective values 40,600 and 73,400 lbs. per sq. in. for the stress at the yield-point ; 42,630 and 97,500 lbs. per sq. in. for the ultimate strength ; 32 and 3 per cent. for the elongation ; and 71.0 and 3.0 per cent. for the reduction of area. For the same samples annealed, he gave the respective values 16,100 and 30,800 lbs. per sq. in. for the yield-point ; 35,500 and 30,800 lbs. per sq. in. for the ultimate stress ; 49.0 and 1.0 per cent. for the elongation, and 78.0 and 1.0 per cent. for the reduction of area. K. Honda gave for the Young's modulus of elasticity, E , and the rigidity, or torsion modulus, n :

Co	0	10	20	30	40	70	80	90	100 per cent.
$E \times 10^{-12}$	2.087	2.030	2.119	2.132	2.068	1.836	1.703	1.934	2.038
$n \times 10^{-11}$	8.34	8.14	8.30	8.86	8.93	7.24	6.30	7.25	7.63

Thus, by adding cobalt to iron, Young's modulus slightly, reaches a

minimum with 10 per cent. of cobalt, Fig. 51, then rises to a maximum with 27 per cent., and then gradually decreases to a second minimum at 82 per cent. Above this concentration, the modulus then rises to the value for cobalt alone. The change of the modulus of rigidity with concentration gives a similar graph with one maximum and two minima. The relative positions of the maxima and minima in the two curves nearly coincide each to each. Z. Nishiyama found the elastic moduli of alloys with 5, 10, 15, and 20 per cent. of cobalt, the respective values $E \times 10^{-6} = 2.159, 2.171, 2.186, \text{ and } 2.238$ kgrms. per sq. cm. H. J. French and W. A. Tucker, W. Oertel and F. Pölzguter, R. C. Good, A. L. Norbury, E. Kothny, A. R. Page and J. H. Partridge, P. Blum, O. J. Steinhart, and A. Schulze studied the physical properties of the alloys.

H. Masumoto and S. Nara found the coeff. of thermal expansion, α , of the iron-cobalt alloys between 30° and 100° to be :

Cobalt	.	.	0	9.91	19.96	29.95	39.93 per cent.
$\alpha \times 10^6$.	.	1.220	1.61	0.985	0.934	0.994
Cobalt	.	.	49.91	59.89	79.86	98.62	100 per cent.
$\alpha \times 10^6$.	.	0.849	0.883	1.169	1.225	1.279

The results, plotted in Fig. 52, show that as iron is added to cobalt, the coeff. of thermal expansion decreases gradually to a minimum at about 47 per cent. of iron,

FIG. 52.—Coefficients of Thermal Expansion of the Iron-Cobalt Alloys.

it then increases to a maximum with 65 per cent. of iron; there is then a gradual decrease to a minimum at 73 per cent. of iron, and thereafter a steady increase to the value for iron alone. The break with 4 per cent. of iron approximates with the point at which the lattice-change occurs. H. Masumoto and S. Nara's results are represented by the continuous line, Fig. 52, and those of A. Schulze, by the dotted line. H. Masumoto

found breaks with 79 and 95 per cent. of cobalt and an inconspicuous maximum with 35 per cent. of cobalt. W. C. Ellis, and E. A. Blomqvist studied this subject. W. Brown found that the sp. hts. of the two steels just indicated were respectively 0.1153 and 0.1157. K. Honda and co-workers found the thermal conductivity, k , in c.g.s. units, to be :

Co	.	0	10	20	50	70	80	90	100 per cent.
k	.	0.1090	0.0944	0.1047	0.1700	0.1721	0.1223	0.0960	0.1653
$K \times 10^{-4}$.	6.02	4.04	4.25	8.90	10.86	7.48	6.21	11.64
$k/K \times 10^6$.	1.82	2.10	2.46	1.91	1.59	1.56	1.54	1.42

The results are plotted in Fig. 53, and they should be compared with the corresponding values for the nickel-iron alloys. The conductivity thus decreases at first with increasing proportions of cobalt; then attains a maximum with about 10 per cent. of cobalt, then rises to a maximum with about 65 per cent., and falls to a second minimum with about 90 per cent., after which it rises to the value for cobalt alone. K. Honda found an increase of about 1 microhm per cm. cube for the addition of 1 per cent. of cobalt to iron. K. Honda's values for the electrical conductivity, $K \times 10^{-4}$ mho, are indicated above, and plotted in Fig. 53. The curves for the thermal and electrical conductivities are similar, and have corresponding maxima and minima. The ratio of the two conductivities is not constant, but varies from 2.4×10^{-6} to 1.4×10^{-6} . T. D. Yensen gave 10 microhms at 20° for the approximate electrical resistance of the Fe_2Co -alloy melted in vacuo and annealed at 900°. This is near the value for iron alone; for the alloy melted in vacuo and annealed at 1100°, the resistance is 10.10 microhms at 20°—for G. W. Elmen's observations, *vide infra*, the cobalt alloys. R. Gans, A. Schulze, and W. C. Ellis studied this subject; and G. Tammann and V. Caglioti, the recovery of the resistance after cold-working. P. W. Bridgman found that the effect of pressure on the sp. resistance, R , of the iron-cobalt alloys can be represented by

$\delta R/R_0 = a\rho + b\rho^2$, where a and b are constants, and the temp. coeff., α , between 0° and 100° :

Iron	0	10	20	33.3	50 per cent.
$30^\circ \begin{cases} a \times 10^6 \\ b \times 10^{11} \end{cases}$	-0.958 0.68	-0.401 0.69	4.32 14	-0.796 0.6	-0.473 2.65
$75^\circ \begin{cases} a \times 10^6 \\ b \times 10^{11} \end{cases}$	-0.960 1.04	-0.305 0.81	6.29 8.0	-0.643 0	-0.467 1.63
$R(30^\circ) \times 10^6$	6.62	8.29	9.91	5.84	5.78
$\alpha \times 10^3$	6.04	5.34	5.63	4.46	4.25
Iron	66.7	80	90.9	100 per cent.	
$30^\circ \begin{cases} a \times 10^6 \\ b \times 10^{11} \end{cases}$	1.153 3.10	1.408 0.73	-1.413 0.62	-2.427 1.14	
$75^\circ \begin{cases} a \times 10^6 \\ b \times 10^{11} \end{cases}$	0.898 4.61	1.346 0.39	-1.360 0.49	-2.450 1.00	
$R(30^\circ) \times 10^6$	10.37	19.34	18.12	10.52	
$\alpha \times 10^3$	2.41	2.18	2.75	6.35	

The results are plotted in Fig. 54, and the breaks represent the change from the body-centred to the face-centred cubic structure as the proportion of cobalt rises beyond about 70 per cent.

FIG. 53.—Electrical and Thermal Conductivities of the Cobalt-Iron Alloys.

FIG. 54.—The Effect of Pressure on the Electrical Resistance of the Fe-Co Alloys.

T. S. Fuller found the thermoelectric force, E millivolts, of copper against iron alloys with 10, 20, and 30 per cent. of cobalt, between 0° and 100° , to be respectively -0.64 , -3.70 , and -3.50 . A. Schulze, and W. C. Ellis studied this subject.

K. Honda measured the intensity of magnetization, I , of a sequence of iron-cobalt alloys for fields of H gauss; the following results are selected from the tables:

5 per cent. Co	$\begin{cases} H \\ I \end{cases}$	$\begin{matrix} 13.7 \\ 1117 \end{matrix}$	$\begin{matrix} 113 \\ 1460 \end{matrix}$	$\begin{matrix} 207 \\ 1551 \end{matrix}$	$\begin{matrix} 689 \\ 1695 \end{matrix}$	$\begin{matrix} 1179 \\ 1710 \end{matrix}$
30 per cent. Co	$\begin{cases} H \\ I \end{cases}$	$\begin{matrix} 25.3 \\ 1160 \end{matrix}$	$\begin{matrix} 113 \\ 1643 \end{matrix}$	$\begin{matrix} 207 \\ 1753 \end{matrix}$	$\begin{matrix} 688 \\ 1844 \end{matrix}$	$\begin{matrix} 1172 \\ 1868 \end{matrix}$
90 per cent. Co	$\begin{cases} H \\ I \end{cases}$	$\begin{matrix} 44.9 \\ 1067 \end{matrix}$	$\begin{matrix} 146 \\ 1202 \end{matrix}$	$\begin{matrix} 243 \\ 1260 \end{matrix}$	$\begin{matrix} 720 \\ 1344 \end{matrix}$	$\begin{matrix} 1160 \\ 1359 \end{matrix}$

The intensity of magnetization, I , for an effective magnetizing field $H=1200$ gauss, is plotted in Fig. 55. The curve has a maximum at about 35 per cent. cobalt, and

FIG. 55.—The Intensity of Magnetization of Cobalt-Iron Alloys.

FIG. 56.—Saturation Capacity of the Cobalt-Iron Alloys.

this is in agreement with the results of A. Preuss, who found that with alloys near Fe_2Co , the saturation capacity is 10 per cent. greater than that of iron; and P. Weiss

and R. Forrer found that alloys with 35 to 45 per cent. of cobalt have a saturation capacity 12.4 per cent. greater than iron. Their results are summarized in Fig. 56, where at low temp., alloys with up to 78 per cent. of cobalt have a body-centred cubic lattice— α -ferrocobalts; those with 78 to 95 per cent. cobalt have a face-centred cubic lattice— γ -ferrocobalts; and those with 95 to 100 per cent. cobalt, a hexagonal lattice of maximum density— H -ferrocobalts. It is considered curious that the intensity of magnetization of an alloy—35 per cent. cobalt—is considerably greater than that of its components when it is remembered that the two elements form a continuous series of solid soln., and no compound. In other analogous cases, the saturation value of magnetization follows the additive rule, varying linearly from one component to another, as found by O. Bloch for the nickel-cobalt alloys. H. Masumoto represented the intensity of magnetization of the iron-cobalt alloys by the curves, Figs. 57 and 58, where F represents ferrite; M, martensite; A, austenite; and H, the alloys with the close-packed, hexagonal lattice. The numbers in Figs. 57 and 58 refer to the strength of the magnetic field in gauss.

FIGS. 57 and 58.—The Intensity of Magnetization of the Iron-Cobalt Alloys.

The alloys of the α - and γ -solid soln. are easily magnetized; the latter, especially has a high maximum permeability comparable with that of permalloy; the solid soln., with the close-packed, hexagonal lattice, is less magnetizable. The magnetization reaches a maximum with about 35 per cent. cobalt. K. Honda said that the true saturation value for iron is probably 2000, much greater than the commonly accepted value, 1700. In that case, the value 1700 is not the magnetic moment of one mol. multiplied by the number of mols. in unit vol., but merely the saturation value practically attainable. The maximum in the curve, Fig. 56, then, means that when iron is alloyed with about 35 per cent. of cobalt, the attainable saturation value for iron is raised, and made to approach the true saturation value. P. Weiss found that the alloy with about 29 per cent. of cobalt, corresponding with Fe_2Co , has a magnetic saturation value 10 per cent. greater than that of soft iron at ordinary temp., and he considered this as evidence of the formation of a cobalt diferride, Fe_2Co , analogous to the assumed nickel diferride, Fe_2Ni . T. D. Yensen obtained about 3 per cent. increase in the magnetization of these alloys when they are melted in vacuo. T. D. Yensen's results are summarized in Figs. 59 and 60; and for G. W. Elmen's results, see the cobalt alloys. Observations were made by O. von Auwers and H. Kühlewein, A. Kussmann and co-workers, T. Spooner, S. J. Barnett and L. J. H. Barnett, T. H. Gant, H. E. Kershaw, W. Oertel, R. L. Sanford, W. C. Ellis, E. H. Schulz and co-workers, F. Stäblein, R. L. Dowdell, J. F. Kayser, J. H. Partridge, S. Evershed, E. Gumlich, J. R. Gier, J. W. Shih, and E. A. Watson. P. Weiss and R. Forrer studied the saturation magnetization of the iron-cobalt alloys between ordinary temp. and the temp. of liquid air.

P. Weiss and R. Forrer found that the magnetization curve consists of two

straight lines connected by a curved portion, one curve slopes upwards from 0 to 13 per cent. of cobalt, and the other downwards from 50 to 78 per cent. of cobalt. The stable form of the alloy is a body-centred cubic lattice— α -ferrocobalt; from 78 to 95 per cent. of cobalt, the lattice is face-centred— γ -ferrocobalt; and from 95 to 100 per cent. cobalt, the lattice is hexagonal. The magnetization curve in the region of

FIGS. 59 and 60.—Magnetization Curves of Iron and Iron-Cobalt Alloys.

γ -ferrocobalt is linear. The magnetic moment of cobalt in the region α -ferrocobalt rich in iron, is 17, but with the α -ferrocobalt rich in cobalt, the magnetic moment of cobalt is 9, and iron 15; in γ -ferrocobalt, the magnetic moment of the cobalt is $8\frac{3}{4}$. For R. Forrer's observations on the two Curie points, *vide* iron; A. Guilbert studied the hysteresis; H. Kühlewein, the Curie points; R. Forrer, the magnetic moment of the alloys; and N. S. Akuloff, the anisotropy of cobalt.

H. T. Kalmus and K. B. Blake reported that the alloy corresponding with Fe₂Co has a saturation value of magnetization from 10 to 13 per cent. higher than that for iron alone; the higher values were obtained with samples prepared in vacuo, and are free from indications of a lack of cohesion. The best castings show a maximum permeability of approximately 13,000 at a density of 8000 gauss.* This is considerably lower than the corresponding value for iron alone, but much greater than that of standard transformer steel. The most important property of the Fe₂Co-alloy is its permeability in medium fields—that is, for a magnetizing force of 50 to 200 gilberts per cm. Through this range, the permeability of the Fe₂Co-alloy is approximately 25 per cent. greater than that of iron alone or of commercial grades of transformer steel or iron. The hysteresis loss of the Fe₂Co-alloy is considerably less than for the best grades of commercial transformer steel at densities of 10,000 gauss, and about the same as for commercial iron at corresponding densities—about 15,000 gauss. C. F. Burgess and J. Aston observed that if the hysteresis loss per cycle with iron alone is unity, that with an alloy with 1.035 per cent. of cobalt is 1.20, and with 47.08 of nickel, 0.53. T. D. Yensen said:

The chief importance of cobalt lies in its magnetic permeability at high densities. An increase here of 25 per cent., when coupled with a low hysteresis loss, is a highly desirable characteristic, for instance, for the teeth of the armatures of dynamo machinery, where the density is always very high. Without going into detail, a few considerations will make this apparent. By increasing the density in the teeth 25 per cent.—which is allowable by using the Fe₂Co-alloy—the armature may be shortened a corresponding amount. As the increased density in the teeth necessarily means an increase in the density of the air-gap, the latter may be shortened so as to keep the field ampere turn for the air-gap and the teeth the same as before. Furthermore, the inside diameter of the armature core may be increased so as to give a smaller core cross-section. The shortening of the armature also shortens the pole pieces, and if a high permeability alloy is used in the field magnetic circuit as well as in the armature, the cross-section of the field core and yoke may also be reduced. From the above reasoning, it follows that the armature, besides requiring less iron, will also require less copper; and the field spools, while containing the same number of ampere turns as before, will also require less copper. The total reduction of iron and copper may thus amount to as much as 25 per cent. each. Passing from the required amount of material to the energy losses in the machine, the I^2R loss is reduced in direct proportion to the reduction in copper used. Furthermore, as the hysteresis loss is lower per pound for the Fe₂Co-alloy than for ordinary iron, and as the eddy current loss is about the same, the total core loss should be considerably less than with ordinary iron, in spite of the increased density. Thus, it would appear possible with this iron-cobalt alloy to construct dynamo machinery considerably lighter than at present, and with a higher efficiency.

K. Honda and K. Kido measured the magnetostriction of cobalt-iron alloys and observed an expansion with alloys with up to 10 per cent. of cobalt; a contraction with alloys having 90 per cent. or more; and alloys with 80 per cent. of cobalt gave an expansion, for fields up to $\frac{H}{t}=300$ or 400 gauss, and a contraction with more intense fields. Y. Masiyama found that the longitudinal magnetostriction, Fig. 61, is the reverse of the transverse effect. The abrupt change with alloys

FIG. 61.—The Effect of the Magnetic Field on Magnetostriction.

near 80 per cent. of cobalt for both the longitudinal and transverse effects, corresponds with the change from the α - to the γ -lattice. The change in vol. is the differential effect of the longitudinal and transverse changes in length. Observations were made by S. R. Williams.

K. Honda and T. Tanaka studied the effect of magnetization on the coeff. of rigidity, K , and the elastic modulus, E . Except in weak fields, the elastic constants are similar, and are illustrated by the curves, Figs. 62 and 63. The elastic constants of cobalt-iron alloys are increased by magnetization, but with alloys having 35 to 55 per cent. of cobalt, a small decrease occurs. The first maximum corresponds with the maximum in the effect of concentration and the A_3 -point in the iron-cobalt system; and the second maximum to that concentration in which the α -lattice changes into the γ -lattice. The change in the elastic constant in these alloys is

about six times greater than it is with carbon steels; and the change in the rigidity is about four times greater than that of the elasticity.

The favourable effects of cobalt in hindering rusting were demonstrated by H. T. Kalmus and K. B. Blake. F. H. Mason, and H. Kirscht studied the effect

FIG. 62.—The Effect of Magnetization on the Elastic Modulus of Cobalt-Iron Alloys.

FIG. 63.—The Effect of Magnetization on the Rigidity of Cobalt-Iron Alloys.

of cobalt on the oxidation of iron. C. F. Burgess and J. Aston observed that when cobalt-iron alloys were exposed to the weather for 162 days from July to February, the losses by corrosion, expressed in kilograms per sq. metre per year; and the losses in grams per sq. cm. when immersed in 20 per cent. sulphuric acid for 1 hour, were as follow:

Cobalt	1.035	2.000	4.055	5.052 per cent.
Atmospheric corrosion	0.239	0.342	0.205	0.205
H ₂ SO ₄ -corrosion	0.705	1.020	0.356	0.257

W. Guertler and T. Liepus found that a 1 : 1-cobalt-iron alloy was attacked in less than 8 hrs. by 10 and 50 per cent. nitric acid; 10 and 36 per cent. hydrochloric acid; aqua regia; 10 per cent. sulphuric acid sat. with sodium sulphate;

carbon dioxide and air; acetic acid; citric acid; tartaric acid; chlorine water; sea-water; sea-water and air; rain-water and air; and a soln. of magnesium chloride. It was not attacked by a 10 per cent. soln. of sodium sulphide in 48 hrs., but a 50 per cent. soln. attacked it in less than 8 hrs.; it was attacked in 8 hrs. by a mixture of 4 per cent. sodium sulphide and 8 per cent. alkali. It was not attacked by a 50 per cent. soln. of sodium hydroxide in 8 hrs., or by a 10 per cent. soln. in 48 hrs., but in the presence of hydrogen dioxide the alloy was attacked. Aq. ammonia—10, 50, and 70 per cent.—had no perceptible action during 48 hrs. A 1:500-soln. of mercuric chloride was not stable in contact with the alloy. The action of these reagents on cobalt-iron-molybdenum alloys in the proportions 10:60:30, 40:40:20, and 60:10:30 was also examined. The corrodibility of the cobalt steels was studied by J. Stodart and M. Faraday, R. Mallet, W. D. Richardson, H. T. Kalmus and K. B. Blake, and O. Bauer and E. Piwowsky. C. F. Burgess and J. Aston exposed plates of iron-cobalt alloys for 162 days from July to February, and expressed the loss in kgrms. per sq. metre per year, and also to the action of 20 per cent. sulphuric acid for 1 hr. and expressed the loss in grams per sq. dm. per hour. The results were:

Cobalt	1.035	2.000	4.055	5.052 per cent.
Air	0.239	0.342	0.205	0.205
Acid	0.705	1.020	0.356	0.257

S. Endo's results, plotted in Fig. 64, represent the corrosion—loss in grms. per sq. cm.—during 5 hrs. action at ordinary temp. with alloys having 0.45 to 0.52 per cent. of carbon and:

Co
	2.01	4.80	10.25	19.40	30.01	39.90	50.50	per cent.
Loss { H_2SO_4	.	0.01154	0.00720	0.00214	0.00130	0.00094	0.00043	0.00047
{ HCl	.	0.00941	0.00532	0.00369	0.00152	0.00116	0.00072	0.00062
{ HNO_3	.	0.02768	0.02062	0.01302	0.02253	0.00156	0.00130	0.00130

Observations were also made by L. Aitchison. D. Saito and H. Okawa studied the nitridization of cobalt steels. J. H. Long and co-workers, and H. Remy and H. Gönning studied contact catalysis of the $2H_2 + O_2$ reaction by the alloy.

FIG. 64.—The Action of Acids on Cobalt-Steels.

FIG. 65.—Phase Equilibria in the Cobalt-Iron-Chromium Alloys.

T. Bergman¹⁵ made some **copper-iron-cobalt alloys** with the idea of obtaining a product resembling nickel. O. Dony-Hénault studied the corrosion of these alloys.

W. Köster studied the **iron-cobalt-aluminium alloys**. J. Pomey and P. Voulet, F. M. Ostraga, T. H. Gant, E. Hughes, F. Roll, E. A. Watson, L. Guillet, J. F. Kayser, E. H. Schulz and W. Jenge, and F. Wever and U. Haschimoto studied the **cobalt-iron-chromium alloys**—the observations of W. Köster are summarized in Fig. 65. K. Honda found that the alloy 36.5 per cent. iron, 5.54

per cent. cobalt, and 9 per cent. chromium has a coeff. of thermal expansion in the annealed state of 10^{-7} , and another alloy very near this in composition has the negative coeff. of -1.2×10^{-6} ; and these alloys are so resistant to corrosion that they have been called *stainless invar*. H. Masumoto studied the alloy. W. Oertel and F. Pölguter, W. Köster and W. Tonn, and W. Köster, studied **cobalt-iron-molybdenum alloys**. H. J. French and T. G. Digges, A. Michel and P. Bénazet, T. D. Yensen, L. L. Wyman and F. C. Kelley, W. Köster, P. W. Bridgman, B. A. Rogers, W. Köster and W. Tonn, and E. Houdremont and H. Schrader studied the **cobalt-iron-tungsten alloys**; K. Honda and S. Saito, W. Oertel and E. Pakulla, and L. Guillet, **cobalt-iron-chromium-tungsten alloys**; and E. Gumlich, and W. Köster and W. Schmidt, the **cobalt-iron-manganese alloys**.

§ 10. Cobalt Suboxide and Monoxide

As in the case of iron, there are three well-defined oxides—cobalt monoxide, or cobaltous oxide, CoO ; cobaltous oxide, Co_3O_4 ; and cobaltic oxide, Co_2O_3 . A number of intermediate oxides have been reported, but their individuality has not been established. An unstable cobalt dioxide, CoO_2 , is also known. I. L. Bell¹ suggested that some cobalt suboxide, perhaps Co_2O , is formed when cobaltous oxide is heated to 327° in a current of carbon monoxide; and when spongy cobalt is heated to dull redness in a current of carbon monoxide. This evidence of the existence of a suboxide is of no value; nor could S. Burgstaller confirm the existence of cobalt suboxide, whilst P. H. Emmett and J. F. Schultz, T. Vorster, G. Gallo, and L. Wöhler and O. Balz considered that it is not probable that the alleged suboxide is a chemical individual; and G. Natta and M. Strada found that the X-radiograms of the alleged cobalt suboxide are like those of mixtures of cobalt and its monoxide.

The preparation of cobalt monoxide.—As indicated in connection with the chemical properties of cobalt, compact cobalt does not readily oxidize in air at ordinary temp., but at a red-heat, the metal is slowly oxidized to the monoxide and afterwards to cobaltous oxide; at a higher temp., cobalt burns with a red incandescence. L. Wöhler and O. Balz found that the oxide obtained by burning cobalt in oxygen contained cobalt monoxide enclosing cobalt which oxidizes only

slowly, and hence the mixture gives rise to the impression that cobalt suboxide is produced. The finely-divided metal, reduced by hydrogen at a low temp., was found by G. Magnus² to be pyrophoric; and the metal reduced at a red-heat was found by H. Hess gradually to take up oxygen. E. Donath also found that spongy cobalt, obtained by reducing at a low temp., is oxidized in air; W. G. Mixter noted that at 12 to 13 atm. press., cobaltous and cobaltous oxides are formed; and H. T. Kalmus observed that cobalt obtained by reducing the oxide in carbon monoxide at 600° is oxidized if withdrawn hot from the furnace. H. P. Walmsley observed that the oxide is formed when cobalt is electrically spluttered in air. P. H. Emmett and J. F. Schultz obtained the oxide by blowing oxygen into molten cobalt. G. C. Winkelblech obtained cobalt monoxide by roasting the powdered metal in air, and also by heating cobaltous hydroxide below 350° in a current of hydrogen, and by calcining the hydroxide or carbonate in air. W. Beetz employed a similar process.

J. L. Proust observed that if cobaltous oxide be vigorously calcined it forms the monoxide, and H. Moissan obtained the monoxide by heating cobaltous oxide in the oxyhydrogen flame. C. D. Braun recommended a red-heat; and J. A. Hedvall, H. T. Kalmus, H. Moissan, 1000°. The transformation of cobaltous to cobaltous oxide occurs at 900° to 1000°, and the product readily takes up oxygen when cooled in air. W. J. Russell heated cobaltous oxide in a current of carbon dioxide, and cooled the resulting monoxide in the same gas; and C. R. A. Wright and A. P. Luff, E. von Sommaruga, R. Schneider, P. Hausknecht, W. Hempel and H. Thiele, and H. Remmler used a similar process. J. L. C. Zimmermann employed carbon dioxide, and also nitrogen for the inert gas.

H. W. Foote and E. K. Smith heated cobaltous oxide in vacuo at 970°, and then 3 hrs. at 1000°, and pumped off the oxygen. T. W. Richards found that at a red-heat, in vacuo, cobaltous oxide yields cobaltous oxide, cobalt, and some higher oxide. M. le Blanc and E. Möbius, G. Natta and M. Strada, W. J. Russell, and G. C. Winkelblech obtained cobalt monoxide by heating the hydroxide in vacuo, or in an inert gas—nitrogen or carbon dioxide; L. Wöhler and O. Balz recommended working at 500° to 600°; and G. Natta and A. Reina, at 200°. T. W. Richards and G. P. Baxter recommended the following procedure:

From the soln. of the metal in nitric acid the pink, granular, cobaltous hydroxide was precipitated by adding an excess of freshly re-distilled ammonia, and subsequently digesting the mixture upon the steam bath in a platinum bowl. This precipitate was collected upon a Gooch crucible in which a circular piece of hardened filter-paper was used instead of an asbestos mat. After drying and converting the mass into the black oxide by ignition with an alcohol lamp, the product was heated to full redness in a boat contained in an evacuated porcelain tube until the weight of the oxide remained constant within 0.1 mgrm.

J. E. Möbius observed that this mode of preparation is not to be recommended, because of the difficulty in dealing with adsorbed oxygen, and he said that the monoxide is best obtained by precipitating cobaltous carbonate from a soln. of cobalt nitrate by the addition of sodium carbonate; and, since the precipitate is very easily oxidized by atm. oxygen, in alkaline soln., the operation should be conducted in an atm. of nitrogen. T. W. Richards and G. P. Baxter themselves said: "With great reluctance the work on cobalt monoxide was abandoned . . . for a substance whose composition varies so widely under conditions which vary so slightly is obviously unfitted for work of the highest accuracy in atomic weight determinations." S. Prasad and co-workers recommended heating the carbonate to 900°.

In view of the fact observed by M. le Blanc and J. E. Möbius, that cobaltous oxide readily absorbs oxygen to form $\text{CoO} \cdot n\text{O}_2$, or else Co_3O_4 , it is an open question if the earlier workers ever obtained pure cobaltous oxide. F. Glaser obtained the monoxide by heating cobaltous oxide in hydrogen at 215° for 8 hrs., and H. T. Kalmus recommended 300°. P. H. Emmett and J. F. Schultz recommended a similar process. H. Moissan heated trihydrated cobaltous oxide in hydrogen at

190° to 200°. I. L. Bell, and L. Wöhler and O. Balz found that the product approximates in composition to the suboxide when cobaltous oxide is heated in carbon monoxide at 419° to 630°.

According to H. T. Kalmus, if cobaltous oxide is heated with 2 or 3 per cent. of carbon at 900°, it forms a yellowish-green cobaltous oxide which he considered to be an allotropic variety of the ordinary oxide—apparently because the oxide prepared at that temp. is grey. The evidence is not sufficient to justify the assumption of allotropy—as usually defined.

T. Vorster, and C. Winkler observed that cobaltic oxide heated in ammonia at 350° forms brownish-yellow cobalt monoxide, and, at a higher temp., the metal. C. M. Loane obtained the oxide for use as a catalyst by the low temp. oxidation of the pyrophoric metal.

C. F. Bucholz obtained what he regarded as cobaltous oxide by heating the nitrate at a red-heat for 1 hour, and then at a white-heat for half an hour; S. Burgstaller said that the decomposition is completed at 750° to 760° in consequence of the reducing action of flame gases; and H. von Wartenberg and W. Gurr added that the decomposition is complete at 1200°. According to F. Bedford and E. Erdmann, when a hot soln. of cobaltous nitrate is treated drop by drop with soluble organic compounds like the carbohydrides, and tartaric acid, finely-divided cobaltous oxide is formed. V. M. Goldschmidt and co-workers heated a mixture of cobalt chloride with sodium carbonate and leached out the alkali; E. L. Reakirt heated cobaltic chloropentamminochloride; M. Lachaud and C. Lepière obtained the oxide, mixed with higher oxides, by the ignition of the sulphate; J. J. Setterberg, G. C. Winkelblech, J. E. Möbius, W. Beetz, and W. J. Russell, by the rapid ignition of the carbonate at a red-heat; H. Rose heated the basic carbonate at 150° in a covered crucible; and F. Emich, S. Holgersson, S. Holgersson and A. Karlsson, P. Hausknecht, and W. G. Mixter heated the carbonate in an atm. of carbon dioxide or nitrogen. The absorption of oxygen by heated cobaltous oxide is illustrated by the experiments of M. le Blanc and J. E. Möbius on the decomposition of cobaltous carbonate, and bringing in oxygen, at different temp.:

Calced at	300°	320°	420°	460°	1050°	300°	420°	450°
Oxygen at	18°	18°	18°	18°	18°	400°	250°	250°
Excess oxygen	6.4	4.63	2.14	1.93	Trace	9.99	7.76	6.65
		Only CoO				Only Co ₃ O ₄		

The higher the temp. of calcination, the less is the amount of oxygen adsorbed. H. Copaux heated cobalt oxalate in a closed vessel, and obtained cobaltous oxide mixed with cobalt; and P. Riban obtained a similar product by heating a 5 per cent. soln. of cobalt formate in vacuo at 175°; and C. D. Braun obtained the oxide by heating cobaltic nitroxypentamminoxalate; and H. V. Regnault found that when cobalt is heated in steam, cobalt monoxide is formed. L. Wöhler and O. Balz observed that the reaction with finely-divided cobalt proceeds quickly, and with sintered cobalt the speed of the reaction is measurable at a red-heat. F. Emich, and P. Sabatier and J. B. Senderens observed that cobalt monoxide is formed when the metal is heated to 150° in an atmosphere of nitric oxide.

A. Schwarzenberg, and M. Ferrières and E. Duport obtained octahedral crystals of the monoxide by the action of steam on heated cobaltous chloride. A. C. Becquerel reported crystals of the monoxide to be formed by heating a mixture of cobaltic oxide with an excess of potassium hydroxide in a silver crucible, and after cooling the fused mass, washing the product with water. A. Schwarzenberg added that the product is potassium cobaltite. J. J. Ebelmen obtained octahedral crystals by heating cobalt borate with lime in a porcelain oven, and washing away the soluble products with cold hydrochloric acid; and A. Duboin, by adding potassium chloride to a fused mixture of potassium hydrofluoride and cobalt oxide or chloride; keeping the mixture at a red-heat for 2 or 3 days; and washing the cold mass with

water. W. Florence observed that octahedral crystals of the oxide are formed in the borax bead; and H. Grandeau, by heating a mixture of cobalt phosphate and potassium sulphate. V. Kohlschütter and J. L. Tüscher prepared an **aerosol** of the oxide.

The cobalt oxides of commerce have no definite composition, but the superfine cobalt oxide, branded FEKO, approximates CoO , and has 77 to 78 per cent. of metal; grey cobalt oxide, GKO, approximates Co_3O_4 , and has 75 to 76 per cent. of metal; prepared cobalt oxide, FKO, approximates Co_3O_4 , and 72 to 74.5 per cent. of metal; black cobalt oxide, SKO, approximates Co_2O_3 , and about 70 per cent. of metal; and black cobalt oxide, RKO, approximates Co_2O_3 and has 66 to 68 per cent. of metal.

According to A. Weissenborn, the oxide prepared by precipitation with hypochlorites contains up to 2 and in some cases 5 per cent. of nickel; and H. T. Kalmus gave for the composition of the commercial oxide:

Co	Ni	Fe	S	As	CaO	SiO_2 (or insolubles)
70.36	1.12	0.82	0.45	0.10	0.50	0.20 per cent.
69.20	1.40	0.50	0.54	—	0.37	1.46 „

with traces of silver. The subject was discussed by O. Barth, W. A. Lampadius, G. Selve, and E. W. von Siemens and J. G. Halske. The sulphur may be present as calcium sulphate, and it can be purified from sulphur by boiling with a soln. of sodium carbonate, washing out the sodium sulphate, and removing the calcium carbonate with dil. hydrochloric acid. H. T. Kalmus thus reduced the sulphur from 0.45 to 0.020 per cent., and the calcium from 0.50 to 0.021 per cent. B. Bogitch removed the sulphur by heating the oxide with wood charcoal—sugar charcoal does not answer, presumably because of the absence of alkali carbonates. E. A. E. Weinberg purified the cobalt by converting it into chloride, volatilizing the chloride, and then oxidizing the chloride. F. Feigl and H. I. Kapulitzas say that all the nickel can be removed as follows:

The soln. is treated with a conc. soln. of potassium cyanide until the precipitate first formed just re-dissolves, an excess of hydrogen dioxide is added to convert the cobalto-into cobalti-cyanide, and the soln. is evaporated to one quarter its volume to destroy the excess of peroxide. On addition of dimethylglyoxime to the hot soln. followed by formaldehyde until its odour is apparent in the soln., the nickel is precipitated as the characteristic red glyoxime compound together with excess of the precipitant; the compound is purified by dissolution in hydrochloric acid and precipitation in the usual way. The method is based on the reaction $\text{K}_2\text{Ni}(\text{CN})_4 + 2\text{H}.\text{CHO} = \text{Ni}(\text{CN})_2 + 2\text{CN}.\text{CH}_2.\text{OK}$. The nickel-free filtrate is evaporated to dryness and the carbon removed by roasting; the washed residue is dissolved in conc. hydrochloric acid, and the cobalt hydroxide precipitated by potassium hydroxide; the well-washed residue is then calcined for oxide.

The properties of cobaltous oxide.—J. L. Proust described cobaltous oxide as a greenish-grey powder; G. C. Winkelblech, as an olive-green powder; W. J. Russell, a pale brown powder; C. D. Braun, a black powder; and J. A. Hedvall, dark red. P. Riban observed that when precipitated from the formate, the colour is rose-red. H. B. Weiser observed a grey- and a red-coloured oxide, due, probably, to differences in the size of the grain. Strongly-heated cobaltous oxide is dark blue, and when this is ground the colour becomes paler, and finally appears to be dark grey. O. C. M. Davis and F. W. Rixon discussed the relation between the colour and the heat of formation. M. Lachaud and C. Lepierre, M. Ferrières and E. Duport, J. J. Ebelmen, H. Grandeau, A. C. Becquerel, J. A. Hedvall, and W. Florence described the octahedral, isotropic crystals, and which belong to the cubic system. The habit is tabular, or acicular. The X-radiograms show that the crystal lattice is of the sodium chloride type. G. Natta and co-workers, and F. M. Bravo said that the cubic, face-centred lattice has four molecules per unit cell; V. M. Goldschmidt and co-workers, and G. Lunde gave $a=4.254 \text{ \AA}$; F. M. Bravo, 4.32 \AA . H. P. Walmsley, 4.247 \AA ; and S. Holgersson and A. Karlsson, $a=4.262 \text{ \AA}$. Observations were made by J. A. Hedvall.

P. P. Ewald and C. Hermann gave 4.25 Å. as the best representative value. V. M. Goldschmidt obtained 2.14 Å. for the distance between the cobalt and oxygen atoms in the lattice. G. Natta and M. Strada's X-ray spectral lines of cobaltous oxide are indicated in Fig. 66. O. Hahn and O. Müller studied the surface of cobalt oxide from observations on the absorbed radium emanations. L. Passerini studied the solubility. J. J. Ebelmen gave 6.52 for the sp. gr. of crystals of cobalt monoxide;

FIG. 66.—X-ray Spectral Lines of Cobaltous Oxide and Hydroxide.

M. Lachaud and C. Lepière, 6.7; A. Du-boin, 6.05; and L. Playfair and J. P. Joule gave 5.597 for the oxide, and after ignition, 5.750. G. Natta and A. Reina, and M. le Blanc and J. E. Möbius gave 6.62; and S. Holgersson gave 6.47 at 18°. For the sp. gr. calculated from the space-lattice, F. M. Bravo gave 6.538; G. Natta and

A. Reina, 6.62; G. Natta and M. Strada, 6.22; S. Holgersson, 6.45; and H. P. Walmsley, 6.455. A. Baladin studied the contraction which occurs during the formation of cobaltous oxide from its elements. G. Bruni and A. Ferrari discussed the solid soln. C. Zengelis said that vaporization can be detected at ordinary temp., but this statement has not been confirmed. M. Watanabe said that the dissociation press. of the oxide at 25° is 4.46×10^{-72} mm. of mercury. According to H. Moissan, cobaltous oxide melts when heated rapidly in the electric-arc furnace, and the cold cake is a mass of reddish crystals. H. Wartenberg and co-workers gave 1935° for the m.p.; P. L. Dulong gave for the heat of formation $(\text{Co}, \text{O}) = 63.8$ Cals.; M. Bertholet, 64.1; J. Thomsen, $(\text{Co}, \text{O}, \text{H}_2\text{O}) = 63.4$ Cals. W. A. Roth and H. Havekoss gave $(\text{Co}, \text{O}) = 57.2$ Cals. for the heat of formation of cobaltous oxide. G. Chaudron gave 61.1 Cals. M. Watanabe gave $\delta Q = -55,768$ cals., and $-50,626$ cals. for the free energy at 25°. W. G. Mixter gave $(\text{Co}, \frac{1}{2}\text{O}_2) = 57.587$ Cals. for the crystalline oxide, and 50.5 Cals. for the amorphous oxide, and P. H. Emmett and J. F. Schultz calculated 56.154 Cals. at 25°. W. Biltz, and G. Chaudron made observations on the subject. R. von Dallwitz-Wegener, G. Beck, and P. H. Emmett and J. F. Schultz calculated values for the free energy; and M. Watanabe gave 14.46 cal. per degree for the entropy at 25°. O. C. M. Davis and F. W. Rixon studied the reaction between the colour and the heat of formation. G. K. Burgess and R. G. Waltenburg measured the emissivity of the oxide for red-light, and B. Monasch found that the radiation of light from a cobaltous oxide electrode in the electric arc is very small. A. Wehnelt said that the oxide is inactive so far as the emission of electrons is concerned when the oxide is fixed on a platinum disc and used as the cathode of a discharge tube. M. Kimura and M. Take-waki found that cobalt oxide absorbs ultra-violet light. F. Jentzsch studied the emission of electrons by the oxide. M. le Blanc and H. Sachse gave 10^{-3} ohm for the electrical conductivity at 18°, and E. Friederich said that it is non-conducting. W. Meyer also measured the conductivity of the oxide. W. Beetz said that the oxide is non-magnetic; and E. H. Williams, that it is ferro-magnetic. P. Hausknecht gave 67×10^{-6} mass unit for the magnetic susceptibility, and E. F. Herroun and E. Wilson, 74.5×10^{-6} . F. Merck and E. Wedekind studied the subject; and Y. Kato and T. Takei prepared magnets from the oxide. W. Klemm and W. Schüth found that the mol. magnetic susceptibility, $\chi \times 10^6$, of cobaltous oxide prepared by calcining the carbonate, was:

H (gauss)	at 500°			at 600°			at 800°		
	20°	190°	440°	20°	215°	250°	20°	220°	440°
765	10,300	9590	8640	9740	8700	8010	9000	7860	7260
1510	9,810	9060	7950	9300	8310	7510	8920	7860	7040

G. C. Winkelblech, and H. Kunheim observed that the olive-green powder turns brown in air; and W. J. Russell, and J. L. C. Zimmermann, that the brown powder is stable in air, but M. le Blanc and J. E. Möbius found that the oxide prepared

by heating the carbonate in vacuo at 350° , becomes black and takes up oxygen on exposure to air until its composition approximates Co_3O_4 without changing its lattice structure. Most observers—*e.g.* W. Beetz, F. Glaser, W. A. Lampadius, W. G. Mixter, H. Moissan, H. Rose, and W. J. Russell—have noted the passage of cobaltous oxide into cobaltosic or an intermediate oxide when it is calcined in air. According to H. W. Foote and E. K. Smith, and J. Hagenacker, the dissociation pressure of oxygen with cobaltous oxide at 1100° is not perceptible, although T. W. Richards and G. P. Baxter said that the dissociation pressure of the oxide at 800° is 1.5 mm. of mercury. This shows that the oxide contained some absorbed oxygen. M. le Blanc and J. E. Möbius found the dissociation press. at 1250° is less than 0.00013 atm. P. H. Emmett and J. F. Schultz calculated the partial press. of oxygen over cobaltous oxide at 1100° to be 6.6×10^{-11} atm.; L. Wöhler and O. Balz calculated for the dissociation press. at 450° , 6.02×10^{-29} atm.; and at 747° , 6.02×10^{-19} atm.; and W. Biltz observed 0.046 atm. at 2477° ; 0.17 atm. at 2627° ; 0.80 atm. at 2827° ; 1.58 atm. at 2927° ; and 2.24 atm. at 2977° . In the oxidation of cobalt in air, cobaltosic oxide is formed between 300° and 431° , and at 869° , solid soln. of cobaltosic oxide and cobalt monoxide are formed. A. A. Read found that the oxide lost all its oxygen when heated in the tip of the oxy-coal gas flame at, say, 1750° . P. Schützenberger observed that at a white-heat, in nitrogen, cobaltous oxide loses in weight about 0.4 per cent. Cobalt monoxide, said H. Moissan, is one of the most stable of the oxides at a high temp. C. M. Despretz studied the reduction of cobalt oxide by **hydrogen** at a red-heat, and W. J. Russell, J. L. C. Zimmermann, and H. Remmler, by the flame gases in a crucible over a Bunsen burner. The direct formation of cobalt by the reduction of the oxide was studied by E. Emich, G. Gallo, W. Müller, H. Remmler, W. J. Russell, C. Winkler, and J. L. C. Zimmermann; L. Wöhler and O. Balz, and G. Gallo observed no intermediate formation of a suboxide (*q.v.*). According to C. R. A. Wright and A. P. Luff, the reduction of cobalt monoxide in hydrogen begins at about 165° , W. Müller said at 197° , H. T. Kalmus, and H. Moissan, 250° ; and F. Glaser, 228° , and he added that reduction is complete at 500° to 600° . G. Gallo observed that the reduction of cobaltous oxide begins at about 118° to 120° , but metallic cobalt is obtained only after 4 hrs. at 400° , 3 hrs. at 500° , 1 hr. at 600° , and 15 mins. at 700° . No sign of a cobaltous suboxide appears as an intermediate stage of the reduction. C. M. Despretz observed that the temp. at which cobalt monoxide is reduced by hydrogen is the same as that at which the metal is oxidized by steam. For the balanced reaction: $\text{CoO} + \text{H}_2 \rightleftharpoons \text{Co} + \text{H}_2\text{O}$, see cobalt. L. Wöhler and O. Balz observed that the equilibrium constant for the reaction: $\text{CoO} + \text{H}_2 \rightleftharpoons \text{Co} + \text{H}_2\text{O}$, is $K = [\text{H}_2\text{O}]/[\text{H}_2]$, or $K = 13.5$ at 450° . G. Chaudron studied the reaction, and obtained $K = 20$ at 1020° . P. H. Emmett and J. F. Schultz, and M. Watanabe found that the equilibrium constants, $K = [\text{H}_2\text{O}]/[\text{H}_2]$, in the reaction at different temp., are:—

	450°	515°	570°	570°	1000°
K	63.2	52.7	45.8	31.3	21.1

The free energy of the reaction is -3678 cal. at 25° . There is no evidence of the formation of solid soln. of cobaltosic and cobaltous oxides, and this is confirmed by the X-radiograms. Z. Shibata and I. Mori gave for the reaction: $\text{CoO} + \text{H}_2 = \text{Co} + \text{H}_2\text{O}$, the free energy -5450 cal. at 25.1° ; for the heat of the reaction, $-57,820$ cal.; and $\log K = 494.1917 - 1.08690$. W. J. Russell, and T. W. Richards and G. P. Baxter said that cobalt monoxide is but slightly hygroscopic, and that during several weeks' exposure to **air** it absorbed no perceptible oxygen, and after 8 to 9 months' exposure, only traces of a higher oxide were formed. P. Schützenberger added that it does not occlude **oxygen** so readily as nickel monoxide. J. E. Möbius showed that the grain-size of the monoxide prepared in vacuo depends on the temp. of preparation, and that the in-take of oxygen by the monoxide depends on the grain-size, and temp. M. le Blanc and J. E. Möbius showed that when cobaltous oxide takes up oxygen at 18° , the crystal lattice does not change,

but if the oxygen is absorbed at 100° or upwards, the cobaltous oxide lattice is formed and shows that the unstable $\text{CoO} \cdot n\text{H}_2\text{O}$ formed by absorption, passes into the stable Co_3O_4 . The change is rapid at 400° . The absorbed oxygen in $\text{CoO} \cdot n\text{O}$ is either interstitial oxygen (13. 66, 17) or else it is adsorbed on the surface. If the oxide be slowly cooled in air, W. J. Russell, and C. D. Braun observed that a higher oxide is formed. J. L. C. Zimmermann showed that if the oxide be heated in air on a piece of platinum foil, a black higher oxide is formed—according to H. Moissan, as the temp. is raised, the sequence of changes is : $\text{CoO} \rightarrow (\text{Co}_3\text{O}_4 \rightarrow) \text{Co}_2\text{O}_3 \rightarrow \text{Co}_3\text{O}_4 \rightarrow \text{CoO}$. J. Hagenacker observed that when cobaltous oxide is heated in oxygen above the dissociation press. of cobaltous oxide, there is an absorption of oxygen by the cobaltous oxide between 1050° and 1150° . H. Moissan, and E. Frémy observed that some cobaltic oxide is formed when cobalt monoxide is heated in air. H. Rose found that the monoxide is insoluble in **water**. S. S. Bhatnagar and S. L. Bhatia studied the rate of evaporation of adsorbed water from the surface of the oxide ; and A. Quartaroli, and F. G. Tryhorn and G. Jessop, the catalytic action of **hydrogen dioxide**.

R. Wasmuth observed that cobaltous oxide is attacked by **chlorine** at about 250° , and at 550° the reaction is faster—and the presence of carbon favours the attack by chlorine. G. Gore observed that dry **hydrogen fluoride** does not act on the oxide below 0° . H. Rose, and J. L. C. Zimmermann found that the oxide is readily dissolved by dil. **hydrochloric acid**, forming a rose-red soln., and in the conc. acid, forming a deep blue soln. A. Ducelliez studied the action of cobaltous oxide on **hypochlorites**—see 1. 8, 4. J. L. C. Zimmermann found that the oxide dissolves slowly in the cold in **perchloric acid**, and rapidly when heated. Cobalt monoxide dissolves in acids to form cobaltous salts. For example, according to C. F. Bucholz, F. A. C. Gren, J. A. Hedvall, H. Kunheim, W. A. Lampadius, J. L. Proust, P. Schwarzenberg, and J. A. Hedvall, the solubility of the oxide in hydrofluoric, hydrochloric, perchloric, sulphuric, nitric, phosphoric, and arsenious acids which occurs slowly at ordinary temp., and more rapidly at a high temp., forms rose-red soln. ; conc. hydrochloric and sulphuric acids form blue soln. J. L. Proust, and J. J. Setterberg found that cobalt sulphide is formed when cobalt oxide is heated with **sulphur** ; and H. Rose said that when heated with sulphur, cobalt sulphide and sulphur dioxide are produced, and, according to O. Schumann, cobalt oxysulphide is also formed. J. B. Senderens observed that with sulphur in the presence of water, cobalt sulphate and thiosulphate are formed ; and when the mixture is boiled, cobalt sulphate is formed—no thiosulphate. J. J. Ebelmen observed that at a red-heat, **hydrogen sulphide** converts cobaltous oxide into sulphide. H. Rose observed that hydrogen sulphide converts it into cobalt sulphide and water. O. Schumann added that at ordinary temp., water, sulphur, and oxysulphide are formed. C. Matignon and F. Bourion found that at 400° , a mixture of chlorine and sulphur monochloride converts cobaltous oxide into the chloride. The oxide dissolves slowly in cold, dil. **sulphuric acid**, but more quickly in the hot acid. C. Dufraisse and D. Nakae studied the catalytic action on soln. of sodium sulphite.

G. Gore, and E. C. Franklin and C. A. Kraus found that cobaltous oxide is insoluble in liquid **ammonia** ; and E. Divers, that it is insoluble in ammonia with some ammonium nitrate in soln. T. Vorster, C. Winkler, and L. Santi observed that cobalt oxide is reduced to metal when it is heated in a current of ammonia, and some ammonium nitrate is formed. S. Hauser represented the effect of temp. on the press. at constant vol., time constant, and the effect of time on the press. at constant temp., by Fig. 67. J. L. Proust, and F. A. C. Gren said that the oxide is slightly soluble in aq. ammonia, but their results may have been due to the peptization of the oxide by the ammonia, because L. Gmelin, H. Rose, and J. L. C. Zimmermann said that the oxide is insoluble in that menstruum. J. L. C. Zimmermann observed that cobaltous oxide is not changed by a hot soln. of ammonia of sp. gr. 0.95. If air or oxygen has access, cobaltous oxide was found

by J. L. Proust, and G. C. Winkelblech to dissolve in aq. ammonia. E. Frémy, and L. Brugnatelli discussed the formation of amines. M. F. Fogler discussed the preparation of a cobalt oxide-alumina catalyst for the oxidation of ammonia. R. H. Brett found that cobalt monoxide is insoluble in soln. of **ammonium chloride or nitrate**, but H. Rose said that it dissolves in a hot soln. of ammonium chloride, and F. A. C. Gren, and J. L. C. Zimmermann added that as the oxide dissolves, ammonia is evolved, and a soln. of cobalt chloride is formed. L. Santi found that at an elevated temp., dry ammonium chloride reduces cobalt oxide to the metal. J. L. Proust, and F. A. C. Gren observed that the oxide is soluble in a soln. of **ammonium carbonate**. The oxide also dissolves in a soln. of **ammonium thiocyanate**. F. Mich found that **nitric oxide** converts it into cobaltous oxide. H. Rose, and J. L. C. Zimmermann observed that cobalt monoxide is readily dissolved by dil. or conc. nitric acid; a cold or hot acid of sp. gr. 1.315 readily dissolves the oxide. R. Weber found that **phosphorus pentachloride** reacts vigorously with heated cobaltous oxide to form cobaltous and phosphoryl chlorides. H. Bassett and H. S. Taylor observed that **phosphoryl chloride** acts on cobaltous oxide at ordinary temp., and at 100° forms anhydrous cobaltous chloride, and in a soln. of ethyl acetate the reaction results in the formation of a complex salt of cobaltous chloride and ethyl acetate.

FIG. 67.—The Reduction of Cobalt Oxide by Ammonia.

T. Vorster found that cobalt oxide is readily reduced to the metal when it is heated with **carbon**, and C. R. A. Wright and A. P. Luff added that the reduction begins at 450°. The reaction with carbon was studied by G. Tammann and A. Y. Sworykin, and R. Berger and L. Delmas; and the reduction of the oxide by coal, and by wood charcoal, by B. Bogitch. T. Vorster observed that the oxide is reduced by **carbon monoxide**. C. R. A. Wright and A. P. Luff, and F. Glaser found that the reaction with carbon monoxide begins at 115°, and with carbon at about 450°; and I. W. Fay and co-workers, with carbon monoxide at 140°. F. Fischer and co-workers studied the formation of carbides in this reaction. M. Watanabe found the equilibrium constant, $K = P_{CO_2}/P_{CO}$, for the reaction: $CoO + CO \rightleftharpoons Co + CO_2$, and found it ranges between 174.4 at 563° and 23.2 at 861°; M. Watanabe gave for the heat of the reaction, $-11,544 - 3.5T + 0.00305T^2 - 0.062T^3$; and for the free energy, $-11,544 + 8.06T \log T - 0.00305T^2 + 0.031T^3 - 17.65T$. F. Merck and E. Wedekind, Z. Shibata and I. Mori, B. Bogitch, P. H. Emmett and J. F. Schultz, and G. Chaudron studied the reaction. A. Laurent observed that a mixture of equal vols. of carbon monoxide and dioxide reduces cobalt oxide to the metal, and it has no action on cobalt itself. K. Fujimura studied the reduction of carbon monoxide by the cobalt oxide catalyst associated with other oxides. H. Hollings and R. H. Griffith studied the adsorption of hydrocarbons by the oxide. P. Sabatier, and P. Sabatier and P. Mailhe observed that at about 200°, **alcohol** is oxidized by cobaltous oxide to aldehyde; P. Camboulives found that **carbon tetrachloride** at 550° converts cobaltous oxide into chloride, and A. Michael and A. Murphy found that in a sealed tube at 100°, a soln. of chlorine in carbon tetrachloride converts cobaltous oxide into chloride. H. Rose, J. L. C. Zimmermann, and F. A. C. Gren observed that **acetic acid** and **tartaric acid** dissolve the oxide slowly in the cold, and more rapidly when heated; the monoxide is also attacked by **oxalic acid** slowly in the cold, rapidly when heated to form insoluble cobalt oxalate. Oxalic acid forms a cobaltous salt, and any adsorbed oxygen oxidizes the oxalic acid very slowly. H. Bodenbender found that a litre of a soln. containing 418 grms. of **sugar** and 34.3 grms. of lime, dissolves 1.56 grms. of cobalt oxide, and 0.29 gm. when 296.5 grms. of sugar and 2.42 grms. of lime are present. J. Aloy

and C. Rabaut noted that the oxide favours the hydrolysis of the **cyanohydrins**. C. Dufraisse and D. Nakae studied the catalytic oxidation of **acetaldehyde**, **benzaldehyde**, **furfuraldehyde**, **styrene**, and **turpentine**. According to J. Aloy and A. Valdiguié, **hydroquinone**, in a soln. containing ammonium chloride, is

FIG. 68.—Fusion Curves of Mixtures of Zirconia with Nickel and Cobalt Oxides.

oxidized, particularly when warmed on a water-bath. M. Rüger observed no combination with **silica** between 900° and 1200°. Cobalt oxide forms a silicate when heated with silica; J. F. Shepherd studied the system: $CoO-Fe_2O_3-SiO_2$; and M. Billy and M. A. Foex, the solubility of the oxide in fused **glasses**. J. A. Hedvall, S. Holgersson and A. Herrlin, and L. Passerini found that cobalt oxide forms a titanate with **titanium dioxide**, but no compound was observed by J. A. Hedvall, or by H. von Wartenberg and W. Gurr, with **zirconia**; or by J. A. Hedvall, or by S. Burgstaller, with **thoria**. H. von Wartenberg and H. J. Reusch represented the m.p. of mixtures of zirconia and cobalt oxide by the curve, Fig. 68.

According to J. L. Gay-Lussac and L. J. Thénard, and C. M. Despretz, **potassium** and **sodium**

readily reduce the oxide to metal. F. A. C. Gren said that a little cobaltous oxide is dissolved by dil. soln. of **alkali hydroxides**, and J. L. C. Zimmermann said that none is dissolved. For the action of alkali hydroxides on cobaltous oxide, *vide infra*, cobaltic oxide. H. Rose, C. Winkler, E. Donath, and J. L. C. Zimmermann observed that cobaltous oxide is soluble in a conc. soln. of alkali hydroxides, forming intense blue liquids, which were studied by A. Völker, A. Remelé, and E. Donath. The monoxide is insoluble in a soln. of **potassium carbonate**. According to J. Persoz, cobaltous oxide is soluble in a boiling soln. of cerium and nickel nitrates with the precipitation of the oxides. J. J. Berzelius observed that when heated on charcoal, with sodium carbonate, the oxide is readily reduced to metal in the inner blowpipe flame. The indefinite products obtained by heating **beryllium oxide** with cobalt oxide were discussed by J. A. Hedvall, J. J. Berzelius, and C. F. Plattner. The solid soln. furnished by mixtures of **magnesium oxide** and cobalt oxide—including the so-called **magnesia-red**—were discussed by J. J. Berzelius, J. A. Hedvall, S. Holgersson and A. Karlsson, L. Passerini, G. Natta and L. Passerini, and K. A. Hofmann and K. Höschel. Solid soln. are formed when mixtures of cobalt oxide and **calcium oxide** are heated to a high temp.; and they were studied by J. A. Hedvall, G. Natta and L. Passerini, H. J. Reusch and H. von Wartenberg, R. Schenck, and R. Schenck and H. Wesselkock; and J. A. Hedvall, and R. Schenck obtained similar results with **strontium oxide**, and with **barium oxide**. J. A. Hedvall and N. von Zweigbergk studied the action of **barium peroxide**. J. A. Hedvall also studied the reactions with **barium**, **strontium**, and **calcium sulphates**. The so-called *Rinman's green*, *zinc green*, *Saxon green*, and *cobalt green* is produced by calcining mixtures of **zinc oxide** and cobalt oxide—see percobaltites for bibliography. The solid soln. was studied by S. Burgstaller, J. A. Hedvall, and G. Natta and L. Passerini; and the absorption spectrum by R. Hill and O. R. Howell. No chemical combination was observed by J. A. Hedvall, and L. Passerini when mixtures of **cadmium oxide** and cobalt oxide are calcined. J. A. Hedvall, W. Biltz and co-workers, and H. von Wartenberg and H. J. Reusch studied the m.p. of mixtures of **alumina** and cobalt oxide; and S. Izawa, the luminescence of the mixtures. J. A. Hedvall, G. Natta and L. Passerini, M. Rüger, S. Bleekrode, R. Hill and O. R. Howell, and J. G. Gentele discussed the formation of cobalt orthostannate—called *blue céleste*, *cæruleum*, or *ellest blue*—when a mixture of **stannic oxide** and cobalt oxide is heated together;

and J. J. Berzelius, J. A. Hedvall, A. Ditte, and G. Natta and L. Passerini obtained cobalt metastannate similarly. J. A. Hedvall observed no evidence of the formation of a solid soln. or of compound with **lead oxide**. F. de Carli observed that at 250° to 300°, **lead dioxide** oxidizes cobalt oxide to a higher oxide. J. A. Hedvall studied the products with **chromic oxide**—*vide* chromites. J. A. Hedvall, S. Holgersson and A. Karlsson, G. Natta and L. Passerini, R. Schenck, and R. Schenck and H. Wesselskock observed the formation of solid soln. when cobalt oxide and **manganous oxide** are heated together; and J. A. Hedvall, A. Gorgeu, and M. Salinger observed that with **manganese dioxide**, permanganites are formed. S. Holgersson and A. Karlsson, S. B. Hendricks and W. H. Albrecht, G. Natta and M. Strada, S. Veil, J. A. Hedvall, and L. Passerini observed that with **ferric oxide**, a ferrite, $\text{Co}(\text{FeO}_2)_2$, is formed; and solid soln. are formed with **nickel oxide**. J. A. Hedvall studied the action of cobalt oxide on numerous **metal oxides** at 1100° and 1300°. No compounds were observed when cobalt oxide is heated to about 1100° with copper, calcium, strontium, barium, beryllium, magnesium, zinc, and cadmium oxides—*vide infra*, cobaltites. A blue aluminate, $\text{CoO} \cdot \text{Al}_2\text{O}_3$, is formed with **alumina** at 1100°, and at a higher temp., a green aluminate, $4\text{CoO} \cdot 3\text{Al}_2\text{O}_3$. The product—*Thénard's blue*—was studied by L. J. Thénard, J. A. Hedvall, G. Natta and L. Passerini, S. Burgstaller, S. Holgersson, M. Rüger, J. J. Ebelman, R. J. Elliot, R. K. Goslitz, P. Louyet, G. Pokrowsky, R. Schenck and H. Wesselskock, R. Hill and O. R. Howell, and W. Stein. G. Natta and L. Passerini, and J. A. Hedvall observed that no compounds are formed with **lanthanum oxide**, or with **cerium dioxide**. A green chromite, $\text{CoO} \cdot \text{Cr}_2\text{O}_3$, is formed with **chromic oxide**; a green tantalate with **tantalum pentoxide**, and likewise with **columbium pentoxide**; a green vanadate, with **vanadium pentoxide**; and a yellow uranate with **uranium trioxide**; Q. C. Montemartini and A. Vernazza studied the action on soln. of **chromic sulphate**.

The preparation of cobaltous hydroxide.—J. L. Proust,³ W. Beetz, and G. C. Winkelblech showed that when potash-lye is added to a soln. of a cobaltous salt, out of contact with air, a blue precipitate is first formed, this becomes violet, and finally rose-red. The changes are accelerated by a rise of temp. If the soln. of the cobalt salt be poured into the boiling potash-lye, the change in colour is very rapid. When cobaltous carbonate is boiled with the potash-lye, the cobaltous hydroxide first produced appears as a voluminous, blue mass which afterwards becomes violet and ultimately rose-red.

L. J. Curtman and A. D. S. John found that the precipitate can be detected in a soln. of cobaltous nitrate containing 1 part of cobalt in 80,000 parts of soln. H. T. S. Britton, and H. T. S. Britton and R. A. Robinson titrated electrometrically, at 18°, 100 c.c. of a 0.0247*M*-soln. of cobaltous chloride with 0.0900 *N*-NaOH, and the results are shown in Fig. 69. Precipitation began when the e.m.f. was 0.676 volt, $P_H=6.81$, and when 0.9 c.c. of the soln. of sodium hydroxide had been added, and 54.8 c.c. were theoretically required. B. Schrage noted that cobaltous hydroxide shows acidic and basic properties. According to E. Frémy, W. N. Hartley, and W. Traube and B. Loewe, the washed precipitate retains alkali very tenaciously, and hence baryta water has been recommended as a precipitant, followed by washing with hot water; and L. Thompson, and J. L. C. Zimmermann recommended mercuric oxide as precipitant. G. C. Winkelblech emphasized the importance of removing the air from the soln. of cobalt salt and the potash-lye by boiling before they are mixed, since, as shown by J. L. Proust, the moist hydroxide

FIG. 69.—The Electrometric Titration for Cobalt Hydroxide.

rapidly changes its colour in air owing to the formation of cobaltic hydroxide. S. Kern noted cobaltous hydroxide is formed when magnesium acts on a conc. soln. of a cobaltous chloride—hydrogen is at the same time evolved; S. E. Moody, as an intermediate product when a soln. of cobaltous sulphate is hydrolyzed in the presence of potassium iodide and iodate; R. Saxon, when a soln. containing cobalt sulphate is electrolyzed; W. J. Russell, when cobaltous carbonate is hydrolyzed by water; and A. Girard, when cobaltous arsenate is hydrolyzed by hot potash-lye.

As indicated above, the blue hydroxide was obtained by J. L. Proust when a cobaltous salt soln. is treated with aqua ammonia, or alkali-lye in the absence of air. According to W. Beetz, W. A. Lampadius, J. L. Proust, A. Remelé, W. J. Russell, C. W. Stillwell, and G. C. Winkelblech, the formation of the blue hydroxide is favoured by a low alkalinity of the soln., and a low temp. A. Hantzsch recommended using less than the theoretical proportion of alkali-lye; and A. Bernardi found that the optimum proportion of cobalt salt to alkali is 1 : 0.02. G. Hüttig and B. Kassler, and R. Kassler recommended the following procedure for preparing the blue hydroxide :

A soln. of 22 grms. of potassium hydroxide in 300 grms. of water is added drop by drop to a soln. of 50 grms. of hexahydrated cobaltous nitrate dissolved in 1000 grms. of water, in an atmosphere of coal-gas, at 0°. The blue precipitate is washed by decantation ten times with 5 litres of air-free water; and dried over sulphuric acid in a desiccator. The product is free from alkali and nitrates. The blue colour of the washed precipitate becomes less marked, and this is not due to the presence of impurities, or to oxidation.

The observations of W. Beetz, F. Feigl, E. Frémy, F. Gauhe, N. R. Dhar, A. Hantzsch, T. Katsurai, J. L. Proust, A. Remelé, C. W. Stillwell, and G. C. Winkelblech showed that the formation of the rose-red hydroxide is favoured by a high alkalinity, and a high temp. G. F. Hüttig and R. Kassler, and R. Kassler prepared the pink hydroxide as follows :

A soln. of 40 grms. of potassium hydroxide in 500 grms. of water is dropped into a soln. of 40 grms. of hexahydrated cobaltous nitrate in an atm. of coal-gas, at 0°, and the rose-red precipitate is washed with water on a filter, and dried in a desiccator over sulphuric acid. A. Hantzsch washed the precipitate, in an atm. of hydrogen, by hot water, then with alcohol, and ether, and dried it in vacuo. G. Natta and co-workers washed the precipitate successively with water, alcohol, and ether, and then dried it at 80° in an atm. of nitrogen.

W. Beetz said that the blue precipitate first formed is a basic salt; but A. Hantzsch observed that when it is precipitated from a soln. of the sulphate by an insufficient quantity of alkali, and washed with cold water until no more sulphuric acid is removed, the residue always contains much sulphate. Repeated boiling with water free from air, however, gradually removes most of the sulphate without altering the blue colour. The red hydroxide is obtained by precipitating with an excess of alkali, washing with hot water in an atmosphere of hydrogen, and finally washing with alcohol and ether. It retains some water even after prolonged heating in nitrogen at 300°, whilst the blue hydroxide is completely dehydrated at 170°; on the other hand, acetyl and benzoyl chlorides react much more vigorously with the red than with the blue compound. The case is regarded as one of "chromo-isomerism," and the formulæ $\text{Co}(\text{OH})_2$ and $\text{H}_2\text{O} \dots \text{CoO}$ are suggested for the red and blue compounds respectively. The blue precipitation was studied by E. Donath, H. Ditz, F. Reichel, C. Winkler, and C. Tubandt—*vide infra*, hydrated cobaltic oxides. S. R. Benedict found that the change from blue to rose-pink is retarded by the presence of a small amount of nickel salt, and he supposed that the deep blue of nickel cobaltite masks the rose-pink of cobaltous hydroxide. H. B. Weiser added that increasing amounts of nickel salt do not increase the intensity of the blue colour, so that the effect is more likely to be due to the stabilization of the blue hydroxide by nickel hydroxide. The presence of the sulphates of iron(ous), zinc, manganese, magnesium, chromium, copper, and

aluminium; the chlorides of tin and calcium; and the nitrates of lead, cadmium, thorium, and strontium were found by N. G. Chatterji and N. R. Dhar to produce no marked effect. J. A. Hedvall found both the blue and rose-pink precipitates are gelatinous, but apparently pass into microcrystalline forms on standing. H. B. Weiser suggests that the precipitated hydrated oxide is most finely-divided when first formed and thus appears blue; but in the presence of a slight excess of alkali, the highly hydrated mass loses water and becomes denser, so that the colour at the same time changes from blue, through lavender, to rose. The rate of this transformation is hastened by raising the temp., and retarded or stopped by the presence of basic cobalt salts or nickel. H. J. Witteveen and E. F. Farnau noted the change from pink to blue if the pink hydroxide is allowed to stand in contact with cobalt salt soln.

The blue or green, gelatinous precipitate of cobaltous hydroxide even changes to a rose colour. G. C. Winkelblech suggested that the blue precipitate is a basic salt, and that the green colour is due to a partial oxidation. A. Hantzsch said that both the blue- and rose-coloured precipitates are hydrates of cobaltous oxide—one, the blue, is assumed to be $\text{CoO} \cdot \text{H}_2\text{O}$, and the other, the rose, is $\text{Co}(\text{OH})_2$. H. B. Weiser questioned this hypothesis, and attributed the variation in colour to a difference in the grain-size. C. W. Stillwell said that the rose-coloured precipitate is a stable crystalline form, whilst the blue one is amorphous and unstable. Blue is the colour by reflected light, green the colour by transmitted light. G. F. Hüttig and R. Kassler said that the X-radiograms show that both the blue- and the rose-coloured hydrates are crystalline, and that the difference in colour is solely due to grain-size—the blue-coloured one being the more finely-divided. H. B. Weiser and W. O. Milligan said that the X-radiograms show that the blue- and rose-coloured hydrates are crystalline, but that the crystalline forms are different. The blue and green have the same crystalline form, and they call it **α -cobaltous hydroxide** to distinguish it from the rose-coloured or **β -cobaltous hydroxide**. The blue and green preparations owe their difference in colour to a difference in physical character. The green is the colour by transmitted light and the blue is probably a reflected colour, a Tyndall blue (C. W. Stillwell). α - $\text{Co}(\text{OH})_2$ is the unstable form. In the presence of alkali, the α -form dissolves and reprecipitates as the less soluble, stable β -modification. The α - to β -transformation can be prevented or retarded by the presence of strongly adsorbed substances in the soln. from which the α -form precipitates. The blue form is stabilized indefinitely by small amounts of mannitol, sorbitol, dulcitol, sucrose, lactose, maltose, xylose, arabinose, raffinose, galactose, and dextrose. The transformation is retarded by cobalt salts (A. Hantzsch); by $\text{Ni}(\text{OH})_2$ simultaneously precipitated (S. R. Benedict); and by albumin, gelatin, and sulphates. The adsorption is strong even with soln. of relatively low concentration, as would be expected from the marked stabilizing action of the compounds. The order of adsorption is: lactose > maltose > sucrose > raffinose. The peptizing action of the sugars as a result of adsorption on hydrous ferric oxide (A. Dumansky) follows the same order. Cobaltous hydroxide in contact with a soln. of cobaltous chloride undergoes colour transformations from green to blue to lavender. The blue and green substances are mixtures of α - $\text{Co}(\text{OH})_2$, β - $\text{Co}(\text{OH})_2$, and a basic salt $\text{CoCl}_2 \cdot 3\text{CoO} \cdot 3 \cdot 5\text{H}_2\text{O}$. The lavender compound formed on long standing is the pure basic salt.

A. de Schulten prepared crystals of the hydroxide by heating a mixed soln. of hydrated cobaltous chloride (10 grms.) in 60 c.c. of water, and 250 grms. of potassium hydroxide. When solution is complete, the vessel is allowed to stand for 24 hrs., and agitated, if necessary, in order to promote the separation of crystals. Crystals were also prepared by this process by P. Hausknecht; and M. le Blanc and J. E. Möbius, and J. E. Möbius added that the product is contaminated by much alkali, which can be removed by a protracted washing with water. They accordingly preferred to add 125 grms. of potassium hydroxide to a soln. of 10 grms. of hexahydrated cobaltous chloride in 30 grms. of water, in place of A. de Schulten's

mixture. R. Saxon obtained the hydroxide by the electrolysis of water with a cobalt anode.

T. W. Richards and G. P. Baxter, O. F. Tower and M. C. Cooke, and C. W. Stillwell observed that cobaltous hydroxide is peptized when it is repeatedly washed with water; and G. F. Hüttig and R. Kassler added that it is not so easily peptized as cobaltic hydroxide. C. Tubandt prepared **colloidal cobaltous hydroxide** by the anodic dissolution of cobalt in conc. alkali-lye, at a low current density, say 0.2 amp. per sq. dm., and at an elevated temp. The cobaltous hydroxide in soln. is precipitated by shaking with barium sulphate. The colloid does not dialyze. G. Grube and O. Feucht, however, showed that the blue soln. is due to the formation of potassium cobaltite, and not colloidal cobaltous hydroxide. The blue alkaline soln. of cobaltous salts containing glycerol, studied by F. Reichel, are also thought to be hydrosols of cobaltous hydroxide. S. Prakash and N. R. Dhar, N. G. Chatterji and N. R. Dhar, H. Colin and A. Sénéchal, and K. C. Sen and N. R. Dhar studied the peptization of the hydroxide by sucrose, dextrose, lævulose, galactose, lactose, mannose, dextrin, starch, and glycerol. H. B. Weiser suggested that the hydroxide may not be colloidal in glycerol soln. L. Hugouaneng and J. Loiseleur employed glycogen as protective colloid; and A. Dumansky and B. Saprometoff, sodium tartrate, or mannite. A. Müller prepared a colloidal soln. by peptizing the precipitated hydroxide—hydrogel—with a dil. mineral acid. The hydroxide is shaken up in a flask with water, and the acid or salt soln. added in successive portions until a clear liquid is obtained. The mixture should be well boiled after each addition. O. F. Tower and M. C. Cooke prepared the colloidal soln. by dialyzing a soln. of cobalt tartrate in the presence of an alkaline soln. of potassium tartrate; and O. F. Tower, by the action of alcoholic *N*-KOH on a soln. of cobalt acetate in glycerol. N. R. Dhar and S. Ghosh, and K. C. Sen and N. R. Dhar peptized cobaltous oxide with alkali-lye. C. Paal and H. Boeters, and Kalle and Co. prepared colloidal soln. from soln. of the sulphate, using the fission products of albumin (protalbates, lysalbates, alkali albumoses, etc.) as protective colloids, and dialyzing the liquid. F. E. Lloyd and V. Moravek, and Wo. Ostwald and K. Popp obtained rhythmic rings of cobaltous hydroxide by pouring aq. ammonia on a gelatin gel containing cobaltous chloride. In some cases a spiral is obtained instead of rhythmic bands. They were studied by N. G. Chatterji and N. R. Dhar. A. and E. Lottermoser studied the ageing of the hydroxide.

The properties of cobaltous hydroxide.—Analyses of cobaltous hydroxide, by J. L. Proust, W. Beetz, G. C. Winkelblech, and L. Schaffner, agree with the formula $\text{Co}(\text{OH})_2$. G. C. Winkelblech said that cobaltous hydroxide is a rose-red powder, and W. Beetz added that the brownish tinge observed by J. L. Proust is due to aerial oxidation to cobaltic hydroxide. C. W. Stillwell observed that freshly-precipitated cobaltous hydroxide is green to yellowish-green by transmitted light, and is gelatinous, laminar, amorphous, and metastable. The blue colour is essentially a reflected colour; it is probably a Tyndall blue scattered by small crystal nuclei which form within the amorphous matrix as the gelatinous precipitate ages to the crystalline form. The freshly-precipitated hydroxide tends to change to the rose-coloured hydroxide, which is granular in appearance and is the stable, crystalline form. No other crystalline forms were produced; the light blue, aged precipitate is crystalline, but it has the same structure as the rose-coloured hydroxide. The blue of the aged precipitate is also structural. Adsorbed cobalt chloride inhibits crystal growth, favours the formation of the green precipitate, and hinders that of the rose. Freshly-precipitated nickelous hydroxide is laminar and amorphous, and tends to stabilize the corresponding amorphous cobalt hydroxide. The change from green to blue of freshly-precipitated cobaltous hydroxide is not due to oxidation. For the blue due to oxidation, *vide infra*, hydrated cobaltic oxides. If a soln. of cobaltous chloride is added to potash-lye in amounts greater than the mol. ratio 1 : 1.5, and the precipitate is allowed to remain in contact with the mother-liquor, ageing occurs and the colour of the

precipitate changes from green to blue to rose; the final rose-coloured precipitate is a basic salt of cobalt and is the only crystalline product formed under the experimental conditions; the blue is a mixture of the rose and the green; and the green is amorphous, containing small amounts of crystalline hydroxide and basic salt.

The deep-violet powder obtained by A. de Schulten consists of microscopic, brownish-red, elongated rhombic prisms grouped in needles; but G. Natta and co-workers showed that the crystals are trigonal. A. de Schulten said that the crystals are pleochroic, being rose-red along *a*, rose-yellow along *b*, and pale brownish-yellow along *c*. The double refraction is about 0.04. The X-radiograms of the crystals were found by G. Natta and co-workers to correspond with a uniaxial, rhombohedral lattice having $a=3.19$ Å., and $c=4.66$ Å., or $a:c=1:1.46$. There is one molecule per unit cell. G. Natta and M. Strada's X-ray spectral lines of the hydroxide are shown in Fig. 71. V. M. Goldschmidt and co-workers discussed the subject.

The X-radiograms of cobalt and nickel hydroxides simultaneously precipitated show that the two compounds are isomorphous. The sp. gr. calculated from the space-lattice data is 3.75. A. de Schulten found 3.597 at 15°. The hydroxide loses water when heated over 100°, and the colour becomes green or black. In an inert gas, or in vacuo, as shown by M. le Blanc and J. E. Möbius, C. F. Bucholz, F. Gauhe, J. E. Möbius, G. Natta and M. Strada, W. J. Russell, B. M. Tassaert, L. J. Thénard, and G. C. Winkelblech, cobaltous oxide is formed. According to G. F. Hüttig and R. Kassler, and R. Kassler, the dehydration curves of blue and pink hydrated cobaltous oxides, at 10 mm. press., Fig. 70, show that with freshly-precipitated material, the water-content at first falls rapidly with rise of temp. until it contains about 1.5 mols. of water to each mol. of cobaltous oxide, after which it decreases slowly with rise of temp. up to 168°, when it has the composition $\text{CoO} \cdot \text{H}_2\text{O}$ (approx.). At this temp. there is considerable loss of water at constant temp., the composition changing to about $\text{CoO} \cdot 0.4\text{H}_2\text{O}$, which again loses water steadily with rise in temp. At 300°, 0.1 mol. of water is still held by the cobaltous oxide. The difference between the rose and blue forms of hydrated cobaltous oxide is one of fineness of division only; the blue form is more finely-divided. The two forms have identical X-ray spectra, distinct from that of anhydrous cobaltous oxide. On heating either form with water, a more stable product, containing less water and showing the above phenomena to a much less marked extent, is formed. This stabilization is more rapid with the blue than with the rose form. T. Katsurai said that in an autoclave, under a press. of 20 atm., the hydroxide is not changed. J. Thomsen gave for the heat of formation $(\text{Co}_2\text{O}_3, \text{H}_2\text{O}) = 63.4$ Cals., and for the heat of reaction with hydrogen sulphide $(\text{Co}(\text{OH})_2, \text{H}_2\text{S} \cdot \text{H}_2\text{O}) = 17.41$ Cals. E. Peterson found the heat of neutralization with hydrofluoric acid to be 13.245 Cals.; J. Thomsen gave for the heat of neutralization with hydrochloric acid, 10.57 Cals.; with nitric acid, 10.546 Cals.; and with sulphuric acid, $\frac{1}{2}\text{H}_2\text{SO}_4$ aq., 12.336 Cals. P. A. Favre and J. T. Silbermann obtained rather lower values. P. H. Emmett and J. F. Schultz calculated for the free energy, E , of the reaction $\text{Co}_3\text{O}_4 + \text{H}_2 = 3\text{CoO} + \text{H}_2\text{O}$, at 370°, 515°, and 800°, respectively, -39.197, -36.539, and -44.717 Cals. Steam does not form cobaltous oxide when passed over cobaltous oxide at 500°. The ratios of steam to hydrogen necessary to oxidize the cobaltous oxide at 370°, 515°, and 800°, are, respectively, 2.4×10^{12} , 1.3×10^{10} , and 1.3×10^9 . H. W. Vogel studied the absorption spectrum of cobaltous hydroxide; F. Allison and E. J. Murphy, the magneto-optic properties; and G. Wiedemann, and S. Veil, the magnetic properties. A. Quartaroli gave 40.6×10^{-6} mass unit; and P. Hausknecht, 140×10^{-6} mass unit for the magnetic susceptibility.

Fig. 70.—Dehydration Curves of Blue and Pink Hydrated Cobaltous Oxides.

Both the blue and rose-red hydroxides have absorption bands at 640μ and 585μ ; and there is complete absorption beyond about 675μ in both cases; and there is also a band at 560μ with the blue and at 520μ with the rose-red form. Observations were made by W. J. Russell.

H. Copaux found that cobaltous hydroxide is attacked by hydrogen at 375° to 380° ; and G. F. Hüttig and R. Kassler, said that the reduction of the blue hydroxide occurs in 20 hrs. at 300° , and in 8 hrs. at 550° . A. de Schulten said that the crystals of cobaltous hydroxide are not altered by exposure to air; but, as observed by W. Beetz, A. Bernardi, J. J. Berzelius, F. Feigl, A. Hantzsch, G. F. Hüttig and R. Kassler, J. L. Proust, L. J. Thénard, G. C. Winkelblech, and J. L. C. Zimmermann, the fresh precipitate readily oxidizes in air and as the proportion of cobaltic oxide increases, the colour changes from blue to green, olive-green, and dirty brown. According to R. H. Brett, J. L. Proust, S. Kern, and J. B. Rogojsky, the hydroxide is very sparingly soluble, or insoluble in water, but G. Almkvist observed that a litre of water dissolves 3.18 mgrms. of cobalt hydroxide. H. T. S. Britton gave for the solubility product $[\text{Co}^{++}][\text{OH}]^2 = 1.6 \times 10^{-18}$. The oxidation of cobaltous hydroxide by hydrogen dioxide was studied by R. Fischer, A. H. McConnell and E. S. Hanes, and P. Pellini and D. Meneghini; the oxidation of cobaltous hydroxide by lead dioxide, by H. Rose, and O. W. Gibbs; and by other agents as indicated in connection with the higher oxides of cobalt. According to C. F. Bucholz, S. Kern, J. L. Proust, J. B. Rogojsky, A. de Schulten, C. W. Stillwell, B. M. Tassaert, O. F. Tower and M. C. Cooke, G. C. Winkelblech, and C. Winkler, C. Reichard found that the freshly-precipitated hydroxide in the cold and in contact with barium dioxide, turns grey, and finally black. The hydroxide readily dissolves in acids, forming salts.

J. L. Proust observed that cobaltous hydroxide is oxidized by chlorine water; and the action of electrolytic chlorine in alkaline soln. was studied by E. Hüttner. O. Ruff and W. Menzel showed that fluorine monoxide oxidizes cobaltous hydroxide, suspended in water, to form a peroxide. The action of potassium hypochlorite or hypochlorous acid on cobaltous hydroxide was studied by O. Popp, F. Field, C. D. Braun, A. Terreil, E. and B. Klimenko, A. Brochet, E. Mitscherlich, R. Böttger, T. Fleitmann, F. Stolba, and E. Hüttner—*vide infra*, cobalt dioxide. According to T. Döring, the cobalt hydroxide is oxidized, and some oxygen as well as potassium chloride and chlorate are formed. The proportion of cobaltous hydroxide can be made so small that the transformation of the hypochlorite cannot be effected by a purely chemical process; and the proportion of oxygen evolved does not depend on the proportion of cobalt oxide employed. Consequently, the cobalt hydroxide here acts as a catalytic agent. At 100° , in alkaline soln., oxygen and potassium chloride are formed, but no chlorate is produced. Hypochlorous acid at 100° furnishes oxygen and hydrochloric acid, and the latter may be partly oxidized to form chlorine and cobaltous chloride. With chlorine in alkaline soln. in the presence of cobalt hydroxide, the reaction is symbolized: $2\text{Co}(\text{OH})_2 + 2\text{KOH} + \text{Cl}_2 = 2\text{Co}(\text{OH})_3 + 2\text{KCl}$. Temperature is an important factor. With the theoretical proportion of chlorine in potash-lye, T. Döring found that at 100° , or a higher temp., oxygen and potassium chloride, free from chlorate, are formed. At a lower temp., only part of the oxygen of the hypochlorite initially formed is liberated, and the remaining part is present as hypochlorite mixed with chloride. When chlorine is bubbled into a soln. of alkali-lye, more hypochlorite may be formed than can be decomposed by the catalyst cobalt hydroxide, and when all the potash-lye has been transformed into hypochlorite, etc., F. Förster observed that some chlorate may be produced. At 100° or over, the more rapid catalytic action on the hypochlorite results in a reduced yield of chlorate. The formation of chlorate by the secondary action of chlorine on the unconverted hypochlorite was discussed by G. Lunge and L. Landolt, F. Oettel, F. Förster, and T. Döring. A. J. Balard observed the oxidation of cobaltous hydroxide by bromine. T. Döring found that when bromine or hypobromite acts on alkali-lye in the presence of cobalt

hydroxide, free oxygen and alkali bromate are formed. The primary action of bromine is to form a mixture of bromide, and hypobromite. When liquid bromine is added to the alkali-lye, the proportion of bromate formed depends on the conc. of the lye, whether the bromine or alkali-lye is in excess, and on the temp. If the bromine is introduced drop by drop, or in the state of vapour, a greater proportion of oxygen is evolved than when liquid bromine is employed. This is because the cobalt hydroxide has a greater chance of inducing the decomposition of the hypobromite to oxygen and bromide than is the case when the liquid bromine acts in a more concentrated form. The action of iodine and of hypoiodites was studied by R. L. L. Taylor, T. Döring, and E. Hüttner. There is no development of oxygen, and the whole of the alkali which reacts with the iodine forms iodate, nor does potassium hypoiodite furnish oxygen, and it is in this respect unlike the hypochlorite and hypobromite. S. E. Moody, and S. R. Benedict found that the hydroxide is oxidized by potassium iodate in accord with the equation: $6\text{Co}(\text{OH})_2 + \text{KIO}_3 + 3\text{H}_2\text{O} = 6\text{Co}(\text{OH})_3 + \text{KI}$.

J. B. Senderens found that when treated with sulphur and water, cobaltous hydroxide forms cobalt sulphate and thiosulphate. E. Hüttner represented the action of potassium persulphate on cobaltous hydroxide by the equation: $2\text{Co}(\text{OH})_2 + \text{K}_2\text{S}_2\text{O}_8 + 2\text{H}_2\text{O} = 2\text{Co}(\text{OH})_3 + \text{K}_2\text{SO}_4 + \text{H}_2\text{SO}_4$; and similarly with ammonium persulphate. A. de Schulten said that the crystals are insoluble in aq. ammonia. R. H. Brett found that the hydroxide is soluble in soln. of ammonium salts—sulphate, chloride, nitrate, or succinate; but A. de Schulten found that the crystals are insoluble in a cold soln. of ammonium chloride, but soluble in a warm soln. H. Grossmann found that the hydroxide is soluble in a boiling soln. of ammonium thiocyanate. C. A. Wurtz found that the hydroxide is insoluble in methylamine and in amylamine. W. Traube and B. Löwe found that the hydroxide dissolves in ethylenediamine, and forms a complex salt. E. Saint-Evre studied the transformation of the hydroxide into $\text{K}_3[\text{Co}(\text{NO}_2)_6] \cdot n\text{H}_2\text{O}$, by the action of an excess of potassium nitrite. H. Rose found that hypophosphites, in the cold, form cobalt hypophosphite; and A. Hantzsch added that phosphoryl chloride reacts vigorously with the hydroxide. C. Reichard observed that the hydroxide is not changed by arsenic trioxide in alkaline soln.

F. and E. Rodgers found that cobaltous hydroxide is readily dissolved by a soln. of potassium cyanide. T. Döring observed that when cyanogen acts on alkali-lye in the presence of cobalt hydroxide, there is no formation of free oxygen. He showed that neither at ordinary temp. nor at 100° is there any development of gas when cobalt hydroxide acts on a soln. of potassium cyanate. In the reaction, J. von Liebig observed that when precipitated cobalt hydroxide stands in contact with a soln. of the cyanate, ammonium and potassium carbonates are formed. C. D. Braun studied the action of potassium ferricyanide; and D. Bhaduri and P. Ray represented the reaction: $3\text{Co}(\text{OH})_2 + 2\text{KOH} + 2\text{K}_3\text{FeCy}_6 = \text{Co}_3\text{O}_4 + 4\text{H}_2\text{O} + 2\text{K}_4\text{FeCy}_6$. A. de Schulten said that the crystals are soluble in warm dil. acetic acid; J. Spiller observed that the hydroxide is not precipitated by potassium hydroxide in the presence of citric acid, or ammonium citrate. A. Job, and W. Wernicke found that a soln. of sodium tartrate forms a violet soln. with cobalt hydroxide; and with a boiling soln. of the tartrate, a complex salt is formed. H. Rose, and F. Field observed that tartaric acid, and also citric acid hinder the precipitation of cobalt hydroxide from soln. of its salts by alkali hydroxides; and H. Ditz, C. Tubandt, and F. Reichel noted a similar result with glycerol—*vide supra*, colloidal cobaltous hydroxide. A. Dumansky and B. Saprometoff found that sodium tartrate is more strongly adsorbed from aq. soln. than is the case with sodium succinate. According to N. N. Mittra and N. R. Dhar, the induced reactions involving the oxidation in air of cobalt hydroxide as primary reaction may have the oxidation of nickel hydroxide as a secondary reaction; and the oxidation of sodium sulphite as primary reaction with the oxidation of cobaltous hydroxides as secondary reaction. R. H. Brett found the hydroxide to be insoluble in a soln. of potassium

hydroxide; but E. Donath said that it forms a blue soln. with hot soln. containing over 30 per cent. of potassium or sodium hydroxide—*vide supra*. A. de Schulten found that when the hot soln. in alkali hydroxide is cooled, microscopic crystals of cobaltous hydroxide separate out on cooling. The hydroxide is soluble in a conc. soln. of potassium carbonate. A. Hantzsch observed that the rose-red hydroxide reacts with acetyl chloride and with benzoyl chloride more vigorously than is the case with the blue hydroxide. A. Bernardi and G. Piacentini observed that the hydroxide forms compounds with nitrophenols. F. Feigl studied the autoxidation of the rose-red hydroxide, and observed that it has the power of colouring benzidine blue, and the reaction has been used as a test for cobalt; toluidine behaves like benzidine. G. Natta and L. Passerini observed that cobaltous hydroxide forms a complete series of solid soln. with magnesium and manganous hydroxides, and a partial series of solid soln. with zinc hydroxide. O. Hahn and O. Müller studied the adsorption of radiothorium by the hydroxide.

§ 11. Cobaltous Oxide and Intermediate Oxides

H. Moissan¹ said that cobaltous oxide is formed by allowing pyrophoric cobalt to burn in air. P. Sabatier and J. B. Senderens obtained this oxide by heating cobalt in air—S. Burgstaller said at 300° to 431°, and E. Donath observed that only the surface of the compact metal is so oxidized. F. Emich obtained this oxide by heating the metal in nitric oxide, but P. Sabatier and J. B. Senderens obtained cobaltous oxide in this way. W. Beetz, T. Carnelley and J. Walker, H. Hess, G. F. Hüttig and R. Kassler, F. Merck and E. Wedekind, C. F. Rammelsberg, G. C. Winkelblech, and J. L. C. Zimmermann obtained **cobaltous oxide**, Co_3O_4 , by heating cobaltic oxide or hydroxide in air; and H. Moissan, by heating any of the

oxides of cobalt to 1000°. C. F. Rammelsberg found that the same oxide is formed when cobaltous oxide, hydroxide, carbonate, or oxalate, or, according to H. Rose, the basic carbonate, or a hydrated cobaltous oxide is heated to redness in air or oxygen—at a higher temp. the oxide formed corresponds with Co_3O_4 . The conversion of cobaltous oxide into cobaltous oxide by calcination in air was observed by W. A. Lampadius, W. G. Mixter, W. J. Russell, and J. L. C. Zimmermann; H. T. Kalmus recommended a temp. of 640°; H. Moissan, and J. Pionchon, 900° to 1000°—but, added P. Hausknecht, the conversion to cobaltous oxide is not complete; according to L. Wöhler and O. Balz, and M. le Blanc and J. E. Möbius, the conversion is complete at 100° to 400° in an atm. of oxygen; and J. Milbauer found that at 480°, and in oxygen at 12 atm. press., the cobaltous oxide contains traces of higher oxides. F. Emich obtained cobaltous oxide by heating cobaltous oxide in nitric oxide at 400°. F. Glaser, S. F. Hermsbädt, J. L. Proust, T. W. Richards and G. P. Baxter, and L. J. Thénard obtained cobaltous oxide by roasting cobaltous hydroxide; and C. F. Rammelsberg, H. Hess, W. Beetz, P. Hausknecht, and G. C. Winkelblech found that at too high a temp. some cobaltous oxide is present. J. L. C. Zimmermann obtained cobaltous oxide by calcining the precipitate obtained by the action of mercuric oxide on a soln. of a cobalt salt. C. D. Braun, C. F. Bucholz, S. Burgstaller, P. H. Emmett and J. F. Schultz, E. Frémy, V. M. Goldschmidt and co-workers, W. Hempel and H. Thiele, J. A. Hedvall, G. F. Hüttig and R. Kassler, R. Kassler, G. Natta and M. Strada, and H. Remmler obtained it by calcining cobalt nitrate, at temp. between 300° and 800°; and F. Merck and E. Wedekind used a molten mixture of potassium and sodium nitrates at 300°, and obtained crystals of the oxide; they found 350° to be too high a temp. A. Schwarzenberg, and J. L. C. Zimmermann obtained crystals of cobaltous oxide by heating a dry mixture of ammonium chloride and cobalt oxalate or chloride in air or oxygen, and extracting the product with hot, conc. hydrochloric acid. A. Gorgeu obtained cobaltous oxide in crystals by passing moist air into molten cobaltous chloride at a bright red-heat, for 5 or 6 hrs., and adding more cobalt chloride from time to time to make up for that lost by volatilization, etc. The cobaltous oxide is produced by moisture and oxidizing gases, and not by moist carbon dioxide, or by dry air. K. Jelinek and A. Rudat passed oxygen over cobaltous chloride at 550°; and T. Vorster, passed a mixture of ammonia and air over the heated chloride. Crystals of cobaltous oxide were also made by H. Hess, and S. Holgersson by heating the chloride with sodium carbonate; A. Schwarzenberg, with potassium chloride, or manganese dioxide; S. Holgersson, and L. Thompson, with potassium chlorate; and P. Gucci, with potassium nitrate. W. Hempel and H. Thiele, and F. Strohmeier obtained cobaltous oxide by roasting the sulphide; C. F. Rammelsberg, W. L. Dudley, W. G. Mixter, W. J. Russell, H. W. Foote and E. K. Smith, H. Rose, J. A. Hedvall, and S. Holgersson, by heating the carbonate or basic carbonate; and C. F. Rammelsberg, R. Schneider, and H. Hess, by heating the oxalate in air or oxygen—G. Chaudron recommended a temp. of 600°. O. W. Gibbs and F. A. Genth obtained cobaltous oxide in octahedral crystals by calcining cobaltous aquopentamminochloride, and other complex amines were found by J. L. Bell, C. D. Braun, H. Copaux, N. W. Fischer, E. Frémy, S. M. Jørgensen, G. von Knorre, C. Krause, A. Laugier, J. von Liebig, G. A. Quesneville, J. B. Rogojsky, E. Saint-Evre, G. Schroeder, A. Schwarzenberg, and L. J. Thénard, similarly, to yield cobaltous oxide. G. Grube and O. Feucht noted that cobaltous oxide is formed during the anodic oxidation of cobalt in potash-lye at low potentials.

The products obtained by calcining the oxides and salts of cobalt in air, is a black, or steel-grey, powder. A. Schwarzenberg, O. W. Gibbs and F. A. Genth, and A. Gorgeu said that the crystals are octahedral, and A. Gorgeu added that the angles are very different from those of hausmannite, so that cobaltous and manganous oxides are not isomorphous; but G. Natta and M. Strada found that the crystals of cobaltous oxide, and of zinc cobaltite, $\text{Zn}(\text{CoO})_2$, are isomorphous; and that the X-radiograms of cobaltous oxide correspond with a cubic lattice of

the spinel type, with 8 mols. per unit lattice, having the parameter $a=8.05$ Å., and volume 253.61×10^{-24} . G. Natta and M. Schmid gave $a=8.02$ Å.; S. Holgersson, $a=8.11$ Å.; S. B. Hendricks and W. H. Albrecht, $a=8.04$ Å.; and P. P. Ewald and C. Hermann, $a=8.07$ Å. The observations of G. Natta and M. Strada on the X-ray spectral lines are shown in Fig. 71. J. A. Hedvall, and G. Lunde made observations on the subject. S. B. Hendricks and W. H. Albrecht observed that the X-radiograms of cobaltous oxide resemble those of magnetite, but the differences in the lattice dimensions indicate that the atoms are closer in cobaltous oxide, but the structure is the same in both cases, as well as in the case of cobaltous ferrite. The observations of S. Holgersson and A. Karlsson, and G. Natta and M. Strada on the isomorphism of cobaltous oxide with the spinels, are discussed in connection with the cobaltites. C. F. Rammelsberg obtained 5.833 to 6.296 for the sp. gr. G. Natta and co-workers calculated 6.21 from the space-lattice data; G. Natta and L. Passerini, 6.11; S. Holgersson, 6.005; and S. B. Hendricks and W. H. Albrecht, 6.17. H. H. Stephenson discussed the mol. vol.; and F. Fischer and co-workers, the thermoelectric power.

C. D. Braun found that the black oxide is hygroscopic, and C. F. Cross added that it is converted into the hemitrihydrate, when it is exposed to moist air. When heated to bright redness, A. Gorgeu said that cobaltous oxide is gradually converted into cobaltous oxide, and that the curve for the transformation is continuous, *i.e.* without breaks. When cobalt monoxide is heated in air to dull redness, it absorbs oxygen, but at a higher temp. the oxygen is again partially expelled. H. Moissan found that cobaltous oxide is completely transformed into cobaltous oxide at temp. exceeding 1000° ; and L. Wöhler and O. Balz found that in a current of carbon dioxide, cobaltous oxide begins to decompose at 600° . H. W. Foote and E. K. Smith gave for the dissociation press., p mm., of cobaltous oxide:

	800°	850°	900°	910°	950°	970°
p	10	28	144	183	521	765 mm.

The dissociation press. of the oxygen, p atm., for the reversible reaction: $\text{Co}_3\text{O}_4 \rightleftharpoons 3\text{CoO} + \frac{1}{2}\text{O}_2$, was found by L. Wöhler and O. Balz to be $p=4.16 \times 10^{-28}$ at 450° ; W. Biltz gave 0.045 at 837° , 0.32 at 937° ; 0.78 at 977° ; and 1.74 at 1037° ; and M. le Blanc and J. E. Möbius, 0.16 at 880° . J. A. Hedvall obtained 952° for the dissociation temp. of cobaltous oxide made from the nitrate at 450° ; and when prepared from the carbonate at 450° , the dissociation temp. is 922° . J. Hagenacker observed that the dissociation press. of cobaltous oxide at 953° is 547 mm., and at 984° , about 1045 mm. G. Kröger studied the thermal dissociation of the oxide. J. E. Möbius found that there is a state of equilibrium, $\text{Co}_3\text{O}_4 \rightleftharpoons 3\text{CoO} + \frac{1}{2}\text{O}_2$. S. Burgstaller found that from the dissociation temp. of cobaltic oxide, 372° to 373° , to a point between 705.5° and 869° , cobaltous oxide is stable, and above that temp., cobaltous oxide is stable. The exact transition points cannot be determined because, he said, regions of solid soln. of the one oxide in the other must be traversed. Cobaltous oxide is formed between 300° and 431° , and, at 869° , there is a region where there are solid soln. of cobaltous and cobaltous oxides. The existence of these regions of solid soln., and the slow speed of dissociation have misled many chemists into assumptions involving the existence of *zahlreiche unwahrscheinliche Kobaltoryde*. L. Wöhler stated that changes in the dissociation press. of an oxide at a constant temp. are due to the formation of solid soln., and not, as supposed by A. J. Allmand, to changes in the sizes of the molecules. M. Watanabe gave for the dissociation press., 23 mm. at 855° ; 81 mm. at 897° ; 174 mm. at 928° ; and 438 mm. at 960° . Below 928° , the system is bivariant and the dissociation press. depends on the composition; the system then becomes univariant when two solid

FIG. 71.—The X-ray Spectral Lines of Cobaltous Oxide and Hydroxide.

soln. of CoO , and Co_3O_4 are formed. At 960° the system is bivariant. The thermal value of the reaction: $\text{Co}_3\text{O}_4 \rightleftharpoons 3\text{CoO} + \frac{1}{2}\text{O}_2$, is $\delta Q = 38,972 - 0.75T + 0.00025T^2$; and the free energy, $\delta F = 38,972 + 1.73T \log T - 0.00025T^2 - 36.07T$; and for the reaction: $3\text{Co} + 2\text{O}_2 = \text{Co}_3\text{O}_4$, $\delta Q = -206,074$ cal. at 25° , and $\delta F = -181,355$ cal. at 25° .

J. E. Möbius, and M. le Blanc and J. E. Möbius noted that cobaltous oxide absorbs oxygen, forming the system $\text{Co}_3\text{O}_4.n\text{O}_2$, to such an extent that the analysis makes it appear as if an oxide higher than Co_2O_3 were formed, although the lattice of Co_3O_4 has undergone no change. Although the system $\text{CoO}.m\text{O}_2$ readily passes into Co_3O_4 , the system $\text{Co}_3\text{O}_4.n\text{O}_2$ shows no tendency to form the higher oxide Co_2O_3 . Indeed, the so-called dry methods of preparing cobaltic oxide all yield a solid soln. of oxygen in cobaltous oxide. A. A. Read said that when cobaltous oxide is strongly heated in the oxyhydrogen flame, it yields metallic cobalt, and as the metal cools it becomes tarnished with a film of oxide. According to W. G. Mixter, the heat of formation of cobaltous oxide from its elements is $(3\text{Co}, 2\text{O}_2) = 193.4$ Cals.; and from amorphous cobaltous oxide, $(3\text{CoO}, \text{O}) = 41.9$ Cals. W. Biltz calculated values from observations on the dissociation press. M. le Blanc and H. Sachse gave 10^{-4} mho for the electrical conductivity at 18° ; and K. Friederich gave 240,000 ohms per sq. mm. for the resistance. C. C. Bidwell found the thermoelectric force against lead, at different temp., furnishes a linear curve. A. Schwarzenberg said that, unlike ferrous oxide, cobaltous oxide is non-magnetic. F. Merck and E. Wedekind gave 32×10^{-6} mass unit for the magnetic susceptibility; P. Hausknecht gave 34.4×10^{-6} mass unit; and E. F. Herroun and E. Wilson, 39.6×10^{-6} to 43.6×10^{-6} mass unit. S. Meyer, and R. H. Weber measured the vol. susceptibility.

When cobaltous oxide is heated in **hydrogen**, it is reduced first to cobaltous oxide (*q.v.*), and then to the metal; W. Müller said that the reduction begins at about 200° ; F. Glaser, at about 207° ; and L. Wöhler and O. Balz, at 350° . G. Gallo said that the reduction of cobaltous oxide by hydrogen begins at about 90° —*vide infra*, cobaltic oxide. L. Wöhler and O. Balz found that the equilibrium constant of the reaction: $\text{Co}_3\text{O}_4 + \text{H}_2 \rightleftharpoons 3\text{CoO} + \text{H}_2\text{O}$, is 34.4 at 450° , whilst that for $\text{CoO} + \text{H}_2 \rightleftharpoons \text{Co} + \text{H}_2\text{O}$, is 13.5 at the same temp. B. Neumann and co-workers discussed the catalytic effect of the oxide on the oxidation of carbon monoxide.

I. L. Bell found that in the presence of water, cobaltous oxide is attacked by **iodine**. G. Gore observed no action by liquid **hydrogen fluoride** at -6.6° . C. D. Braun, C. F. Bucholz, F. Emich, O. W. Gibbs and F. A. Genth, A. Laugier, F. Merck and E. Wedekind, J. L. Proust, J. B. Richter, E. Saint-Evre, and A. Schwarzenberg observed that **hydrochloric acid** slowly dissolves cobaltous oxide, with the evolution of chlorine; the solution is at first green, then blue, and in air it becomes violet, and, on the addition of water, red. O. Brunck observed that when heated with **potassium chlorate**, ozonized oxygen is evolved at 250° , and vigorously at 300° . M. le Blanc and J. E. Möbius found that a hydrochloric acid soln. of **potassium iodide** dissolves cobaltous oxide at 60° .

T. Hiortdahl observed that **hydrogen sulphide** at a red-heat converts cobaltous oxide into the sulphide Co_2S_3 ; and F. Bourion, and C. Matignon and F. Bourion, that **sulphur monochloride** attacks cobaltous oxide below the b.p. of sulphur, forming sulphur, sulphur dioxide, and cobaltous chloride. O. W. Gibbs and F. A. Genth, J. L. Proust, and A. Schwarzenberg found that cobaltous oxide dissolves only slowly in **sulphuric acid**, and on heating the mixture, oxygen is evolved.

U. Sborgi and E. Gagliardo found that **boron nitride** at 750° to 900° decomposes cobaltous oxide with the formation of nitric oxide, and boric oxide, and when heated in air, cobaltous oxide is re-formed. C. Winkler observed that **ammonia** gas reduces the heated oxide; and E. Divers observed that the oxide is soluble in an ammoniacal soln. of **ammonium nitrate**; with molten **ammonium thiocyanate**, C. D. Braun obtained a blue mass. W. Beetz, C. F. Bucholz, O. W. Gibbs and

F. A. Genth, J. L. Proust, and A. Schwarzenberg found that **nitric acid** dissolves the oxide slowly, but not completely, and oxygen is evolved.

As indicated in connection with cobalt, **carbon** reduces the oxide to the metal; and likewise also **carbon monoxide**. E. Frémy observed that **acetic acid** forms a green to brown soln. G. C. Winkelblech, and E. Saint-Evre noted that with **oxalic acid**, carbon dioxide is evolved, and M. le Blanc and J. E. Möbius found that the reaction: $\text{Co}_3\text{O}_4 + \text{H}_2\text{C}_2\text{O}_4 = 3\text{CoO} + 2\text{CO}_2 + \text{H}_2\text{O}$, is quantitative. According to J. E. Möbius, cobaltous oxide dissolves in oxalic acid, forming a cobaltous salt, and absorbed oxygen oxidizes the acid very slowly, whilst the excess oxygen above cobaltous oxide oxidizes the oxalic acid very quickly. The results show that the product $\text{Co}_3\text{O}_4 \cdot n\text{O}_2$, or $\text{CoO} \cdot m\text{O}_2$, is not cobaltic oxide. A. Kutzelnigg studied the adsorption of **potassium ferrocyanide** by the oxide. T. M. Felton observed a eutectic with **silica** at 1325° , and 68 per cent. Co_3O_4 .

J. L. Gay Lussac and L. J. Thénard found that molten **sodium** or **potassium** reduces the oxide to the metal; and, as indicated in connection with the preparation of the metal, **aluminium** also reduces the oxide to metal. According to A. Schwarzenberg, molten **sodium hydroxide** dissolves cobaltous oxide, forming a blue mass. J. A. Hedvall and N. von Zweigbergk studied the action of **barium peroxide**. H. Hess said that with molten **potassium hydroxide**, a brown mass is formed; J. L. Proust, that alkali-lye in the presence of tin, forms a red liquid; and C. Winkler, and E. Donath, that the boiling lye forms a blue soln. T. M. Felton studied the reaction with **alumina**; and S. Roginsky and E. Schultz, the catalytic action of the oxide on the thermal decomposition of **potassium permanganate**, and of **ammonium dichromate**. O. W. Gibbs and F. A. Genth observed that molten **potassium sulphate** dissolves cobaltous oxide.

C. D. Braun found if basic cobalt carbonate, $3\text{CoO} \cdot 2\text{CO}_2 \cdot 4\text{H}_2\text{O}$, be heated to 200° , the black residue corresponds with the *dihydrate*, $\text{Co}_3\text{O}_4 \cdot 2\text{H}_2\text{O}$. He also obtained a hydrate by heating cobaltous ferricyanide with alkali-lye; and G. Natta and M. Strada, by treating a soln. of cobaltous sulphate with alkali-lye and bromine, and drying the precipitate at a high temp. in air. H. Rose obtained what appeared to be $4\text{Co}_3\text{O}_4 \cdot 3\text{H}_2\text{O}$, by treating the basic carbonate, $5\text{CoO} \cdot 2\text{CO}_2 \cdot 4\text{H}_2\text{O}$, in a similar manner. E. Frémy, and C. F. Cross, as indicated previously, said that when the anhydrous oxide is exposed to a moist atmosphere, the composition of the product approaches $2\text{Co}_3\text{O}_4 \cdot 3\text{H}_2\text{O}$. G. Natta and M. Strada's observations on the X-ray spectral lines are indicated in Fig. 71. According to O. W. Gibbs and F. A. Genth, when a soln. of cobaltic aquopentamminsulphate is boiled, the *trihydrate*, $\text{Co}_3\text{O}_4 \cdot 3\text{H}_2\text{O}$, is formed, and similar results were obtained by A. B. Lamb and J. W. Marden; whilst, according to F. Mawrow, the same product is obtained when cobaltous hydroxide is treated with potassium persulphate, in neutral soln., and the black product boiled with dil. nitric acid (1:4). According to W. N. Hartley, the *hexahydrate*, $\text{Co}_3\text{O}_4 \cdot 6\text{H}_2\text{O}$, is formed when a cold soln. of cobaltous chloride is decomposed by boiling in vacuo with an eq. quantity of barium hydroxide. When the green product is treated with acetic acid, cobaltous oxide separates. E. Frémy prepared the *heptahydrate*, $\text{Co}_3\text{O}_4 \cdot 7\text{H}_2\text{O}$, by treating a soln. of cobalt salt with an excess of potassium hydroxide, and allowing the mixture to stand for a month in a flask containing oxygen. The brown product contaminated with some potassium salt, is dried in vacuo.

G. Natta and M. Strada said that the crystal lattice of the hydrated cobaltous oxide is the same as that of cobaltous oxide. C. D. Braun observed that the hydrate can be dehydrated only with difficulty; traces of water are retained at 200° ; cobaltous oxide is formed at bright redness, and, on cooling, a layer of cobaltous oxide is formed. According to O. W. Gibbs and F. A. Genth, the hydrated oxide is a dark brown powder, soluble in oxalic acid to form a green soln. which decomposes when heated. C. D. Braun, O. W. Gibbs and F. A. Genth, and F. Mawrow observed that hydrochloric acid dissolves it to form cobaltous chloride with the evolution of chlorine; the hydrated oxide is also soluble in dil. nitric

acid with a protracted boiling, but the conc. acid readily dissolves the hydrate. A. H. McConnell and E. S. Hanes observed that cobalt acetate is formed when the hydrate is treated with acetic acid, and E. Frémy thought that when hydrated cobaltous oxide is treated with acetic or sulphuric acid, cobaltous salts are formed.

Oxides between CoO and Co_3O_4 .—As indicated above, S. Burgstaller² observed no evidence of the formation of intermediate oxides between CoO and Co_3O_4 . There is a region of solid soln. of the two oxides in the vicinity of 869° . The existence of these solid soln., and the fact that the speed of transformation from one oxide to the other may be very slow, explains why numerous workers have obtained intermediate oxides. Again, J. E. Möbius, and M. le Blanc and J. E. Möbius observed that cobalt oxide readily forms solid soln. with oxygen $\text{CoO} \cdot m\text{O}_2$ where the oxygen is not a part of the lattice structure. This unstable system when annealed may form $\text{Co}_3\text{O}_4 \cdot n\text{O}_2$. The absorbed oxygen in cobaltous oxide attacks oxalic acid slowly, whereas if the excess oxygen were present as a higher oxide the attack would be rapid.

C. R. A. Wright and A. P. Luff reported an oxide $\text{Co}_{16}\text{O}_{17}$. G. C. Winkelblech, H. Rose, and W. Beetz reported Co_6O_7 to be formed by heating cobaltous hydroxide in air; W. Beetz, by heating cobaltous chloride or carbonate in air; and H. Rose, and J. M. Krok, by heating the basic carbonate in air. Observations on the Co_6O_7 -oxide were made by C. D. Braun, O. W. Gibbs and F. A. Genth, H. Hess, S. M. Jörgensen, H. T. Kalmus, C. F. Rammelsberg, W. J. Russell, A. Sieverts, E. von Sommaruga, and A. Weissenborn. C. D. Braun, and H. Rose reported Co_4O_5 to be formed by heating the basic carbonate in air at 100° , and P. Sabatier and J. B. Senderens, by burning reduced cobalt in nitrous oxide. Observations were also made by G. Gallo, E. Hüttner, A. Sieverts, and A. Weissenborn.

L. V. Brugnatelli, and J. G. Gentile reported Co_8O_9 to be formed as an *octohydrate*, $\text{Co}_8\text{O}_9 \cdot 8\text{H}_2\text{O}$, when the freshly-precipitated cobaltous hydroxide is heated with soln. of potassium hydroxide until it forms a dark brown product. W. N. Hartley obtained a buff-coloured *henahydrate*, $\text{Co}_8\text{O}_9 \cdot 11\text{H}_2\text{O}$, by the action of an excess of barium hydroxide on a boiling soln. of cobalt nitrate in vacuo. G. C. Winkelblech, C. D. Braun, and J. G. Gentile obtained the *icosihydrate*, $\text{Co}_8\text{O}_9 \cdot 20\text{H}_2\text{O}$, by exposing the blue ammonia precipitate of cobaltous hydroxide to air until it becomes yellow, or by adding potassium hydroxide to a mixture of cobalt sulphate and ammonia, and warming the green precipitate at 30° until it becomes yellow. E. J. Mills reported the hydrated oxide, $\text{Co}_4\text{O}_5 \cdot n\text{H}_2\text{O}$, to be formed by heating cobaltic hexamminochloride with 30 to 40 times its weight of water in a sealed tube at 70° to 100° .

Between 372° , the dissociation temp. of cobaltic oxide, and a temp. between 705.5° and 869° , cobaltous oxide is stable. The transformation temp. are difficult to determine because of the formation of solid soln. of one oxide in the other. J. E. Möbius, and M. le Blanc and J. E. Möbius observed that cobaltous oxide can form a solid soln. with oxygen, $\text{Co}_3\text{O}_4 \cdot n\text{O}_2$, even to the case where the cobaltous oxide dissolves more oxygen than corresponds with cobaltic oxide, without forming that oxide. Indeed, J. E. Möbius said that all the described processes for preparing cobaltic oxide really furnish solid soln. of $\text{Co}_3\text{O}_4 \cdot n\text{O}_2$. When the solid soln. is treated with oxalic acid, the excess of oxygen corresponding with cobaltous oxide rapidly oxidizes the acid whilst the free oxygen reacts only slowly, thus showing that the solid soln. is cobaltous and not cobaltic oxide. G. Natta and M. Strada could not prepare oxides or hydroxides of cobalt between Co_2O_3 and Co_3O_4 as chemical individuals. The X-radiograms showed that the products were all mixtures.

E. J. Mills reported the Co_6O_7 -oxide, and also Co_7O_{10} , formed by heating cobaltic hexamminochloride or chloropentamminodichloride with 2 mols. of cobalt chloride and water in a sealed tube at 100° ; and R. L. Taylor, by treating a neutral soln. of cobalt chloride with bromine and an alkaline earth carbonate, obtained oxides ranging from Co_7O_{11} to Co_9O_{14} . T. Bayley reported $\text{Co}_{12}\text{O}_{19}$ -oxide; and T. Bayley, G. Schroeder, and G. Rousseau, the Co_3O_5 -oxide. N. McCulloch reported an oxide, $\text{Co}_{13}\text{O}_{19}$, to be formed by the action of hydrogen dioxide, in the presence of free alkali, on a boiling soln. of a cobalt salt. C. R. A. Wright and A. P. Luff, and N. McCulloch reported the hydrate, $\text{Co}_3\text{O}_4 \cdot n\text{H}_2\text{O}$, to be formed by boiling a cobaltous salt with an excess of potash-lye and bromine, or with a strongly-alkaline soln. of hydrogen dioxide. R. L. Taylor likewise

obtained $\text{Co}_3\text{H}_{14}\cdot n\text{H}_2\text{O}$; C. R. A. Wright and A. P. Luff, T. Bayley, E. Hüttner, R. Fischer, and G. Schroeder, $\text{Co}_{12}\text{O}_{19}\cdot n\text{H}_2\text{O}$; A. Carnot, E. Hüttner, A. B. Lamb and co-workers, and G. Schroeder, $\text{Co}_5\text{O}_8\cdot n\text{H}_2\text{O}$; T. Bayley, K. A. Hofmann and H. Hiendlmaier, G. Natta and M. Strada, G. Schroeder, and G. C. Winkelblech, $\text{Co}_3\text{O}_5\cdot n\text{H}_2\text{O}$; and J. Thomsen, $\text{Co}_4\text{O}_7\cdot 7\text{H}_2\text{O}$.

§ 12. Cobaltic Oxide and its Hydrates

L. V. Brugnatelli noted the formation of a salt of a higher cobalt oxide when the yellow soln. of cobaltous hydroxide in aq. ammonia is exposed to air. The liquid becomes red. The product was studied by J. B. Trommsdorff.¹ J. L. Proust thought that **cobaltic oxide**, Co₂O₃, is formed when cobaltous nitrate is calcined at a low enough temp. in air; and G. C. Winkelblech added that to expel all the nitric acid, the product, calcined at about 184°, should be finely ground, and gently heated in a porcelain crucible until red vapours are no longer evolved. H. Hess recommended decomposing cobaltous chloride in the dry way with sodium carbonate, and washing the residue with water. If the cobaltic oxide be prepared at too high a temp., it passes into cobaltous oxide. According to L. Thompson, the oxide is formed when a conc. soln. of cobaltous chloride, mixed with 1 to 1.5 parts of potassium chlorate, is evaporated to dryness, heated to dull redness and then extracted with water.

The brown, or brownish-black powder, according to the analyses of G. C. Winkelblech, J. L. Proust, E. Rothoff, and W. Beetz, corresponds with Co₂O₃, but J. E. Möbius, and M. le Blanc and J. E. Möbius doubt very much if cobaltic oxide can be produced in the dry way, although the hydrated oxide can be readily prepared. The alleged cobaltic oxide is considered to be a solid soln. of oxygen in cobaltous oxide—*vide supra*. N. A. Held observed that cobaltic oxide forms a **colloidal solution** in alcohol, when hydrochloric acid is used as peptizing agent.

G. Natta and M. Strada examined the X-radiograms of what they considered to be cobaltic oxide and its hydrates, Fig. 72; and they concluded that cobaltic oxide has probably a hexagonal or rhombohedral structure with a cell having the edge $a=4.64$ Å., and $c=5.75$ Å., so that $a:c=1:1.24$. There are two molecules per unit cell. G. Lunde, and V. M. Goldschmidt and co-workers found that the X-radiograms of cobaltic oxide corresponded with those of cobaltous oxide, and said that it is doubtful if cobaltic oxide has been prepared. The X-ray spectrum of cobaltous oxide (Fig. 71), however, differs from that of cobaltic oxide. The calculated sp. gr. is 5.34; W. Herapath reported 5.322 at 16.5° ; P. F. G. Boullay, 5.600; and L. Playfair and J. P. Joule, 4.814. H. Hess, and G. C. Winkelblech observed that

FIG. 72.—X-ray Spectra of Cobaltic Oxide and its Hydrates.

cobaltic oxide passes into cobaltous oxide when heated to dull redness, and J. L. Proust observed that at a higher temp., cobaltous oxide is formed. S. Burgstaller found that the dissociation temp. of cobaltic oxide is 372° to 373° at 760 mm. From this temp. up to 705.5° to 869° , cobaltous oxide is the stable form, and beyond that, cobaltous oxide. As indicated above, G. Natta and M. Strada said that cobaltic oxide forms cobaltous oxide at 265° . According to V. M. Goldschmidt and co-workers, G. Lunde, M. le Blanc and J. E. Möbius, and S. Holgersson, the oxide formerly considered to be cobaltic oxide, obtained by calcining cobaltous compounds in air, or treating them with oxidizing agents, is really cobaltous oxide, Co_3O_4 . G. F. Hüttig and R. Kassler said that the product obtained by dehydrating hydrated cobaltic oxide is also cobaltous oxide, but G. Natta and M. Strada prepared cobaltic oxide by heating one of the hydrated forms, and added that no known process of preparation furnishes cobaltic oxide if the temp. employed exceeds 250° ; since at temp. above 265° , the product is cobaltous oxide. W. W. Coblenz studied the reflecting power of the oxide; and A. H. Barnes, the X-ray spectrum. K. Friederich gave 194,000 ohms per sq. mm. for the electrical resistance; and H. Reynolds found for the resistance, R , of pencils made by compressing powdered cobaltic oxide:

	18°	268°	349°	464°	600°	770°
R . . .	22,800	1410	712	249	107	26.4 ohms

and the electrical conductivity of another sample exhibited a transformation in the vicinity of 900° , Fig. 73. This was thought to be due to the change of cobaltic into cobaltous oxide—from the above, it is more likely to have been $\text{Co}_3\text{O}_4 \rightarrow \text{CoO}$. The conductivities of mixtures of ferric and cobaltic oxides were also measured.

According to W. Müller, hydrogen reduces cobaltic oxide at 125° to cobaltous oxide, whilst cobaltous oxide is reduced at 320° ; H. Moissan said that cobaltic oxide is reduced to cobaltous oxide at 190° to 200° , and at 250° , to cobalt; S. Hauser said that hydrogen begins to reduce cobaltic oxide at 225° to 240° ; C. R. A. Wright and A. P. Luff, at 110° ; and F. Gläser, at 182° . G. Gallo said that there is an incipient reduction of cobaltic oxide by hydrogen at 80° to 85° ; and at a higher temp. there is a transient formation of cobaltous oxide which begins to be reduced to cobaltous oxide at about 90° . In the presence of water vapour, at 70 mm. press., the reduction of cobaltic oxide by hydrogen begins at 95° , and at 110° if the vap. press. of water is

FIG. 73.—Electrical Conductivity of Cobaltic Oxide at Different Temperatures.

92 mm. O. Brunck found that when cobaltic oxide is heated in oxygen to 400° , or the beginning of a red-heat, some ozone is formed. In the dry state, cobaltic oxide cannot be oxidized to cobalt dioxide. According to C. F. Cross, when cobaltic oxide is exposed to a moist atmosphere, it gradually forms $\text{Co}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, or $2\text{Co}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$, and then $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$; the subject was discussed by W. Müller-Erzbach. Cobaltic oxide is decomposed by most acids in the cold with the formation of cobaltous salts. Chlorine is evolved when the oxide is digested with hydrochloric acid, and the reaction was studied by R. Finkener. A. Coehn and M. Gläser said that in consequence of the development of chlorine when cobaltic oxide is treated with hydrochloric acid, this oxide behaves more like lead and manganese dioxides than does ferric oxide—assuming, of course, that cobaltic oxide is a true sesquioxide like ferric oxide. G. J. Fowler and J. Grant observed that when heated with potassium chlorate, at about 250° , the oxygen which is evolved is accompanied by some chlorine. A. F. Benton studied the adsorption of oxygen, and carbon monoxide, and dioxide by cobaltic oxide at 0° and at -79° . When heated with sulphur and water, J. B. Senderens observed that cobalt sulphate and thiosulphate are formed. C. Dufraisse and D. Nakae studied the catalytic oxidation of soln. of sodium sulphite. T. Vorster observed that when cobaltic oxide is heated in dry ammonia, cobaltous oxide is formed, and afterwards cobalt. F. Neumann, and O. Brunck examined the action of cobaltic oxide on carbon; and K. Iwase and M. Fukushima observed that the reduction is favoured by the presence of lime. C. R. A. Wright and A. P. Luff observed that carbon begins to reduce cobaltic oxide at 260° , and carbon monoxide at -11° . F. Bullheimer observed that glycerol does not reduce cobaltic oxide. A. Bonnet said that cobaltic oxide is taken up from ammoniacal soln. by plant fibres. Cobaltic oxide dissolves in acetic acid without immediate decomposition. G. Rauter observed that silicon tetrachloride is decomposed by this oxide, forming silica, chlorine, and cobaltous chloride. C. Dufraisse and D. Nakae studied the catalytic oxidation of acetaldehyde, phenylaldehyde, furfuraldehyde, styrene, and turpentine. S. B. Hendricks and W. H. Albrecht prepared what may be **cobaltic ferrite**, $\text{Co}_2\text{O}_3 \cdot \text{Fe}_2\text{O}_3$ —*vide* the ferrites.

Hydrated cobaltic oxides.—A number of impure forms of hydrated cobaltic oxide has been reported to occur in nature; the mineral **transvaalite**, described by T. B. McGhie and J. Clark, is an oxidation product of cobalt arsenide, and it occurs in black, nodular masses in veins in the quartzite near Middleburg, Transvaal. It is an impure **hydrated cobaltic ferric oxide**. It dissolves in hydrochloric acid with the liberation of chlorine. Its sp. gr. is 3.846, and its hardness, 4.0.

The mineral **heterogenite**, described by A. Frenzel, occurs in the veins of cobalt and nickel ores at Schneeberg, and at Heubach near Wittichen, Baden. It is a decomposition product of smaltite. It is amorphous, and occurs in black or reddish-brown, globular or reniform masses with little lustre. Its composition approximates the **hydrated cobaltic oxide**, $\text{CoO} \cdot 2\text{Co}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$. Its sp. gr. is 3.44, and its hardness, 3. J. Morozewicz described **lubeckite**, $\text{CuO} \cdot m(\text{Mn}, \text{Co})_2\text{O}_3 \cdot n\text{H}_2\text{O}$, a black, colloidal mineral occurring at Miedzianka; the sp. gr. is 4.8, and the hardness, 2 to 3.

The black mineral **heubachite** occurs in thin, soot-like incrustations, or in dendritic or small spherical aggregates, as a secondary product in mines near Heubachtal, Baden; near Alpirsbach, Württemberg; and in Copiapo, Chili. It was described by F. Sandberger, who showed that it is a **hydrated cobaltic nickelic ferric oxide**, $3(\text{Fe}, \text{Co}, \text{Ni})_2\text{O}_3 \cdot 4\text{H}_2\text{O}$. Its sp. gr. is 3.75, and its hardness, 2.5. It is soluble in conc. hydrochloric acid with the evolution of chlorine; the soln. is bluish-green, and it becomes rose-red when diluted with water.

A. Schoep and V. Cuvelier, and V. Cuvelier described a mineral from Mindingi, Katanga, Belgian Congo. The analysis approximates **hydrated aluminium cobaltic oxide**, $(\text{Fe}, \text{Al}, \text{Co})_2\text{O}_3 \cdot \text{H}_2\text{O}$. It was called **stainierite**. It is black, compact, and opaque, with a granular or banded, concentric texture. It is birefringent and pleochroic. Its sp. gr. is 4.137, and its hardness, 4.5. It readily dissolves in hydrochloric acid with the evolution of chlorine. It is possibly isomorphous with goethite.

The oxidation of cobaltous salts in acidic or alkaline soln. furnishes hydrated cobaltic oxide. The composition of the hydrate depends on the concentration of the soln., the temp., the oxidizing agent, etc. Quite a number have reported

the formation of the hydrated oxide without specifying clearly the composition of the product, presumably because that was a secondary consideration to the main purpose of the work. The brown product obtained when precipitated cobaltous hydroxide is exposed to air, was shown by G. F. Hüttig and R. Kassler, and A. Remelé to contain cobaltous hydroxide, and does not consist wholly of cobaltic hydroxide. Various oxidizing agents have been recommended for converting hydrated cobaltous oxide into hydrated cobaltic oxide :

A. Carnot, R. G. Durrant, R. Fischer, G. F. Hüttig and R. Kassler, C. Krause, A. H. McConnell and E. S. Hanes, N. McCulloch, C. Paal and H. Boeters, A. Sieverts, and S. Veil oxidized soln. of cobalt salts with hydrogen dioxide ; O. Brunck, S. W. Parr, S. R. Benedict, and G. Natta and M. Strada, with sodium dioxide ; C. Reichard, with barium dioxide ; O. W. Gibbs, F. Gauhe, C. Krause, and H. Rose, with lead dioxide ; W. Beetz, P. Berthier, C. D. Braun, T. Carnelley and J. Walker, C. F. Cross, E. Frémy, P. Hausknecht, E. Hüttner, W. A. Lampadius, A. H. McConnell and E. S. Hanes, T. Moore, J. L. Proust, A. Quartaroli, C. F. Rammelsberg, H. Rose, C. L. Taylor, J. Thomsen, T. Vorster, and G. C. Winkelblech, with chlorine in alkaline soln. ; G. C. Winkelblech, W. Beetz, C. D. Braun, H. Rose, A. Weissenborn, A. F. Benton, E. Donath, F. Meidert, H. Hess, W. Müller, E. Fleischer, E. and B. Klimenko, S. Veil, and J. Thomsen, with sodium hypochlorite. According to G. C. Winkelblech, if alkali be not added to the soln. of cobalt nitrate after the addition of sodium hypochlorite, the cobalt forms soluble cobaltic nitrate. E. M. Dingler thought it was present in soln. as sodium cobaltite. H. Hess, and R. Böttger oxidized the cobalt salt with bleaching powder ; G. Natta and M. Strada, with potassium chlorate at 150° ; G. Natta and M. Strada, H. Remmler, E. Donath, C. Krause, A. Jorissen, E. Fleischer, G. F. Hüttig and R. Kassler, R. Kassler, F. Merck and E. Wedekind, A. J. Balard, T. Moore, and G. Schröder, with bromine ; E. Hüttner, and E. Donath, with iodine ; S. E. Moody, with iodates ; E. Hüttner, L. Dede, and F. Mawrow, with ammonium or potassium persulphate ; D. Bhaduri and P. Ray, with potassium ferrieyanide ; F. Gauhe, T. W. Richards and G. P. Baxter, C. Krause, and C. Winkler, with potassium permanganate ; S. Kitashima, sodium bismuthate ; and N. W. Fischer, W. Wernicke, A. Coehn and Y. Osaka, A. Coehn and M. Gläser, F. Förster and E. Müller, F. Förster and A. Piguet, H. G. Byers, R. Saxon, E. Müller and F. Spitzer, E. Hüttner, C. Thieme-Wiedtmarckter, G. Grube and O. Feucht, G. Grube, and F. W. Skirrow, by anodic oxidation.

M. le Blanc and J. E. Möbius obtained hydrated cobaltic oxide by adding potash-lye to a soln. of anodically oxidized cobalt sulphate in 8N-H₂SO₄ ; C. D. Braun, A. Carnot, E. Frémy, J. G. Gentile, O. W. Gibbs and F. A. Genth, L. Gmelin, C. Künzel, E. J. Mills, J. B. Rogojsky, and G. C. Winkelblech, by boiling aq. soln. of cobaltic amines, or by treating them with alkali-lye. Other complex cobaltic salts have been employed by S. R. Benedict, H. Colin and A. Sénéchal, E. Fleischer, C. Friedheim and F. Keller, R. Kassler, C. Krause, H. Rose, E. Saint-Evre, A. Stromeyer, and G. F. Hüttig and R. Kassler. G. F. Hüttig and R. Kassler recommended the following process :

Add a soln. of 18 grms. of potassium hydroxide in 50 grms. of water to a soln. of 10 grms. of cobaltic hexamminochloride (or chloropentamminochloride) in 300 grms. of water at 60° ; wash the precipitate by decantation with 5 litres of water, and filter by suction with the exclusion of air ; then wash it with another 5 litres of water ; and dry the product over sulphuric acid in vacuo.

According to W. Beetz, C. F. Bucholz, E. Donath, E. Donath and J. Mayrhofer, L. Gmelin, J. L. Proust, L. J. Thénard, O. Völker, and C. Winkler, cobaltous oxide dissolves in fused potassium hydroxide to form a clear, blue liquid, which with a more prolonged heating turns brown, and cobaltic oxide separates out in brown flakes. The blue liquid solidifies to a blue glass. The formation of the blue soln. by the action of alkali-lye on cobalt was discussed by C. D. Braun, E. Donath, G. Grube, G. Grube and O. Feucht, C. Tubandt, and C. Winkler. Again, J. L. Proust observed that when a soln. of a cobalt salt is dropped into boiling, conc. potash-lye, a blue precipitate is formed, that changes to a red hydrate, and afterwards dissolves to form a blue soln. When the blue soln. is sufficiently diluted with water, cobaltous hydroxide is deposited, but if air has access to the liquor, brown, hydrated cobaltic oxide is precipitated. Similar observations were made by O. Völker, and W. Beetz added that the soln. of cobaltous hydroxide in potassium

hydroxide is colourless if air be rigorously excluded; the blue coloration develops only when air has access to the liquor. C. Winkler showed that the blue soln. is developed when potassium hydroxide acts on reduced cobalt, or on cobaltous oxide, in air. The blue soln. gives reactions characteristic of cobaltic oxide, and he assumed that the blue colour is produced by a *Kobaltsäure*. W. Schulze, and E. Donath showed that a higher oxide is present when the blue colour is developed. The subject was studied by A. Remelé, G. C. Winkelblech, F. Reichel, E. Donath, G. Grube and O. Feucht, W. J. Russell, H. Ditz, and C. Tubandt. For C. W. Stillwell's observations, *vide supra*, cobaltous hydroxide.

G. Grube and O. Feucht observed that in conc. soln. of potassium hydroxide, anodic cobalt dissolves at high current-densities with the formation of a deep blue soln. of potassium cobaltite, $\text{Co} + 2\oplus = \text{Co}^{++}$; and $\text{Co}^{++} + 4\text{OH}' \rightleftharpoons \text{CoO}_2'' + 2\text{H}_2\text{O}$; or $\text{Co}^{++} + 3\text{OH}' \rightleftharpoons \text{HCoO}_2' + \text{H}_2\text{O}$. The electrode potentials of cobalt against blue soln. containing different amounts of cobalt in 8*N*-KOH, show that the blue soln. is potassium cobaltite, and not colloidal $\text{Co}(\text{OH})_2$, as suggested by C. Tubandt. The normal potential of cobalt against potassium cobaltite is -0.52 volt. The anodic oxidation of potassium cobaltite at a platinum anode takes place in 3 stages: (i) at low potentials, cobaltous oxide is formed; (ii) at medium potentials, cobaltic oxide is produced; and (iii) at high potentials, there results a solid soln. of cobalt dioxide in a lower oxide, and oxygen is evolved. The evolution of oxygen at a cobalt anode in alkali-lye involves the formation of cobalt dioxide and its subsequent decomposition into molecular oxygen and cobaltic oxide.

J. L. Proust, A. de Schulten, and C. Tubandt observed that the blue soln. is fairly stable in air, and deposits cobaltous hydroxide only slowly. It can be evaporated very far without decomposition, but when dried, C. Winkler observed the separation of a black oxide; and C. Winkler, and J. L. C. Zimmermann also noted that cobaltous hydroxide is deposited when the soln. is diluted. The soln. was found by C. D. Braun, E. Donath, E. Donath and J. Mayrhofer, J. L. Proust, and J. L. C. Zimmermann to be readily oxidized by air with the separation of cobaltic hydroxide. E. Donath, and C. Winkler also said that the soln. is readily oxidized to cobaltic hydroxide by hydrogen dioxide, and by chlorine. C. Winkler said that the soln. oxidizes potassium iodide, sulphur dioxide, potassium ferrocyanide and indigo, but E. Donath could not confirm this. C. Winkler found that with phosphorus, the blue soln. forms cobalt phosphide; and that carbon dioxide precipitates cobalt carbonate; E. Donath observed that ammonium sulphide precipitates cobalt sulphide; C. D. Braun, and E. Donath, that an excess of potassium cyanide forms potassium cobalticyanide; C. Winkler, that zinc precipitates crystalline cobalt; and C. Tubandt, that barium sulphate precipitates cobaltous hydroxide.

When equal vols. of a soln. of sodium tartrate (50 per cent.), cobalt sulphate (30 per cent.), and sodium hydroxide (30 per cent.) are mixed, a violet-red soln. is obtained, and this on exposure to air develops a green colour which slowly becomes more intense. The green soln. was investigated by F. Field, F. Kehrmann, J. Gibson, H. Marshall, and R. G. Durrant. A. H. McConnell and E. S. Hanes showed that the soln. possibly contain percobaltites of the alkali metals in which CoO_2 takes the place of MnO_2 in the permanganites. A. Job found the at. ratio of Co : O in the green soln. is 2 : 3, *i.e.* $2\text{CoO} + \text{O} = \text{Co}_2\text{O}_3$. R. G. Durrant suggested that derivatives of cobaltic acid, H_2CoO_4 , are present, since the green soln. is also produced by the action of hydrogen dioxide on soln. of cobalt salts in the presence of an excess of alkali hydrocarbonate. A. Job found that with the tartrate soln. just indicated, the amount of oxygen absorbed increases indefinitely under these conditions, but if a quantity of glycerol is added, it reaches a maximum, equivalent to one atom of oxygen for each atom of cobalt present. The cobaltic compound formed requires merely the absorption of an atom of oxygen for every two atoms of cobalt present, and it is suggested that the reaction which takes place may be represented by one of the two following sets of equations: (i) $2\text{CoO} + \text{O}_2 = 2\text{CoO}_2$, followed by $2\text{CoO}_2 + \text{A} = \text{Co}_2\text{O}_3 + \text{A}\text{O}$; or else (ii) $2\text{CoO} + \text{H}_2\text{O}$

$=\text{Co}_2\text{O}_3 + \text{H}_2$, and $\text{H}_2 + \text{O}_2 = \text{H}_2\text{O}_2$, followed by $\text{H}_2\text{O}_2 + \text{A} = \text{AO} + \text{H}_2\text{O}$, where A denotes the acceptor which is an oxidizable compound—in the present case, tartaric acid. The second explanation was suggested by W. Manchot and co-workers; and the first explanation by A. Job, C. Engler, and E. Baur. In confirmation, A. Job found that manganous hydroxide, dissolved in an alkaline soln. of a tartrate, passes first into manganese dioxide and finally into the sesquioxide. Both cobaltous and manganous hydroxides under these conditions also absorb nitrosyl, but whereas the manganese soln. absorbs oxygen fifty times as quickly as the cobalt soln., the latter absorbs nitrosyl at least ten times as rapidly as the manganese solution.

The preparation of definite hydrates of cobaltic oxide.—A number of hydrated cobaltic oxides has been reported. Thus, E. J. Mills said that the *tritadihydrate*, $3\text{Co}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, is formed when a molar proportion of cobaltic chloropentamminodichloride and two molar proportions of cobaltous chloride are heated with water while exposed to the air. The *hemitrihydrate*, $2\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, was reported by E. Hüttner to be formed by drying the tritapentahydrate over conc. sulphuric acid; by treating a soln. of cobalt sulphate with potassium hydroxide and oxidizing the product with potassium persulphate, or with chlorine. C. F. Cross also recommended chlorine for oxidizing cobaltous hydroxide suspended in potash-lye, and drying the product at 100° to a constant weight. G. F. Hüttig and R. Kassler showed that the dehydration curves indicate the existence of a *monohydrate*, $\text{Co}_2\text{O}_3 \cdot \text{H}_2\text{O}$ —*vide infra*. According to F. Mawrow, if 4 grms. of cobaltous hydroxide be suspended in a soln. of 100 grms. of potassium hydroxide of sp. gr. 1.12, and warmed with an excess of potassium persulphate, there is formed a yellow precipitate which turns brown, and then black. It is washed with hot water, and dried over sulphuric acid. When this is treated with warm nitric acid, there remains a brownish-black mass which when dried approximates $2\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ —and it is said that the product is possibly a mixture of Co_2O_3 and $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$. E. Hüttner reported that the *tritapentahydrate*, $3\text{Co}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$, is formed when a soln. of 10 grms. of cobaltous sulphate in a little water is treated with 200 c.c. of a sat. soln. of potassium persulphate; and also when an ammoniacal soln. of cobalt and ammonium sulphates is treated with potassium persulphate.

According to E. Hüttner, when the tritapentahydrate is exposed for 9 days over sulphuric acid, the product passes into the *dihydrate*, $\text{Co}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$. H. Hess, and C. D. Braun also obtained the dihydrate by drying the trihydrate for a week over conc. sulphuric acid. E. Hüttner obtained the dihydrate by treating 10 grms. of cobalt sulphate with an excess of potash-lye, and a hot soln. of 20 grms. of potassium persulphate in 100 c.c. of water; or by treating a soln. of 5 grms. of cobalt sulphate in 150 c.c. of water with 100 c.c. of 20 per cent. potash-lye, and saturating the cold mixture with chlorine. A. Remelé obtained the dihydrate by adding potash-lye to an alcoholic soln. of cobaltous nitrate at 60° to 80° . W. Wernicke, and A. Coehn and M. Gläser also obtained the dihydrate by the electrolysis of a soln. of potassium cobalt tartrate in potash-lye, and drying the product in vacuo.

According to G. C. Winkelblech, and J. L. Proust, the *trihydrate*, $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, or **cobaltic hydroxide**, $\text{Co}(\text{OH})_3$, can be obtained by treating cobaltous hydroxide or carbonate suspended in water, with chlorine—C. D. Braun suspended the hydroxide in a boiling soln. of sodium hydroxide; H. Hess, and R. Böttger used bleaching powder as the oxidizing agent; G. C. Winkelblech, and G. Schröder, sodium hypochlorite; and A. J. Balard, bromine—R. Bernard and P. Job said that probably cobalt dioxide is formed as an intermediate product in the oxidation of cobaltous to cobaltic oxide. G. C. Winkelblech exposed a soln. of a cobaltous salt, saturated with ammonia, in air, until it formed a brown liquid, he then precipitated the product with potash-lye. E. Frémy boiled soln. of the cobalt amines with potash-lye. According to F. Mawrow, when a soln. of cobalt sulphate or nitrate is warmed with an excess of potassium persulphate, a dark brown precipitate, containing $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ mixed with sulphates, is formed. The trihydrate is produced by warming cobaltous hydroxide with potassium persulphate, and, after

washing with water, heating the product at 100° with dil. nitric acid. About one-third of the cobaltous hydroxide is converted to hydrated cobaltic oxide. S. E. Moody treated a soln. of cobalt sulphate with potassium iodide and iodate. A. Coehn and M. Gläser obtained the trihydrate by the anodic oxidation of an alkaline soln. of cobalt tartrate. J. E. Root observed that with a soln. of 0.0870 gm. of cobalt in an alkaline soln. of tartrate, 0.0802 gm. of cobalt was deposited as metal on the cathode, and 0.0122 gm. of $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ was deposited on the anode. C. F. Cross observed that when the hydrated oxide, which has been dried at 100° , is exposed to air saturated with moisture, for a few days, it forms either a *tetrahydrate* or a *pentahydrate*.

G. Schröder, G. F. Hüttig and R. Kassler, and F. Merck and, E. Wedekind observed that precipitated hydrated cobaltic oxide is readily peptized when it is washed with water. C. Paal and H. Boeters, and Kalle and Co. prepared **colloidal solutions** of cobaltic hydroxide with sodium protalbate or lysalbate as protective agent. During dialysis, the cobaltous hydroxide is oxidized to the cobaltic state. By evaporating the dialyzed soln., the product is soluble and the resulting colloidal soln. contains less than 10 per cent. of cobalt. If the colloidal cobaltic hydroxide be prepared in the presence of hydrogen dioxide, a stable, soluble colloid can be obtained with over 20 per cent. of cobalt. F. G. Tryhorn and G. Jessop obtained the colloid by adding ammonia to a mixture of hydrogen dioxide and cobalt chloride soln. The brown sol soon coagulated. L. Hugounenq and J. Loiseleur used glycogen as a protective colloid; and A. V. Dumansky and B. G. Zaprometoff, sodium tartrate and mannitol.

The properties of hydrated cobaltic oxides.—These hydrates are described by G. C. Winkelblech, and others as dark brown powders; and H. Herrenschildt and E. Capelle added that if pure, the colour is light brown. On the other hand, G. F. Hüttig and R. Kassler said that cobaltic hydroxide is black, and that brown preparations contain cobaltous hydroxide. G. Natta and M. Strada's observations on the X-ray spectral lines are summarized in Fig. 72. The hydrate could not be obtained in a definite crystalline form, and the X-radiograms show the lines of cobaltic oxide which is formed on dehydration. G. Natta and M. Strada, G. F. Hüttig and R. Kassler, and F. Merck and E. Wedekind found that all preparations between Co_2O_3 and $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ have the same Co_2O_3 lines. A. Coehn and M. Gläser, and W. Wernicke gave values for the sp. gr. of the hydrate. G. Natta and M. Strada found 4.29 to 4.90 for the sp. gr. of $\text{Co}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, and 4.46 to 4.47 for $2\text{CoO}_3 \cdot 3\text{H}_2\text{O}$. According to G. C. Winkelblech, when the hydrates are heated, water is first evolved, then oxygen and water, until cobaltous oxide is formed which does not part with the remaining water until a red-heat is attained. G. Natta and M. Strada said that the hydrate passes into anhydrous Co_2O_3 if it be heated below 250° —*vide supra*. According to T. Carnelley and J. Walker, the air-dried precipitate has the composition: $5\text{Co}_2\text{O}_3 \cdot 8\text{H}_2\text{O}$, and it retained this composition when heated for 6 hrs. at temp. ranging up to 74° . When heated beyond this, it gradually lost water, and at 100° , it had the composition: $2\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$. This, however, represented a chance stage in a continuous process, for the water was lost continuously up to 260° without any evidence of the formation of a stable hydrate. The loss of water was now rapid, and the composition at 270° approximated $10\text{Co}_2\text{O}_3 \cdot \text{H}_2\text{O}$, and remained almost constant between 280° and 360° , when a further loss occurred. Dehydration was complete at 385° , but, as the last traces of water were expelled, there was also a slight loss of oxygen with the corresponding formation of cobaltous oxide. G. F. Hüttig and R. Kassler obtained the dehydration curves of the hydrated cobaltic oxides, at 10 mm. press., when the oxides were prepared in different ways. The results, Fig. 74, show that when the mol. ratio of water to oxide is less than 3, the water is held more tenaciously than would be expected on the assumption of adhesion or capillarity. Dehydration between the limits 3:1 and 1:1 increases smoothly with rise of temperature, and the ease with which the water can be removed varies with the mode of preparation. No evidence of the

existence of a definite compound intermediate between a mono- and a trihydrate has been obtained. Removal of water from a product having the composition $\text{Co}_2\text{O}_3 \cdot \text{H}_2\text{O}$ takes place at constant temperature, and is usually accompanied by the formation of cobalto-cobaltic oxide. The existence of a definite monohydrate is indicated, and this is supported by the X-radiograms. The last 0.3 mol. of water requires a temp. over 300° before it is expelled.

T. Carnelley and J. Walker observed that the dehydration is almost complete at 280° , and C. F. Cross, and G. C. Winkelblech found that a red-heat is necessary to drive off all the water. According to the f.p. determinations of G. Urbain and A. Debiere, the formula of cobalt acetylacetonate, $\text{Co}\{\text{CH}(\text{COCH}_3)_2\}_3$, corresponds with $\text{Co}(\text{OH})_3$ rather than with $\text{Co}_2(\text{OH})_6$. J. Thomsen found the heat of formation $(2\text{Co}_2\text{O}_3, 3\text{H}_2\text{O}) = 149.3$ Cals.; and $(2\text{Co}(\text{OH})_2, \text{O}, \text{H}_2\text{O}) = 22.58$ Cals. A. H. Barnes studied the X-ray absorption spectrum. G. Grube and O. Feucht gave 0.109 volt for the potential in 8N-KOH at 25° ; and E. Müller and F. Spitzer, 0.4 volt for an anode covered with $\text{Co}_2\text{O}_3 \cdot n\text{H}_2\text{O}$ in ammoniacal soda-lye. E. H. Williams said that the oxide is paramagnetic. A. Quartaroli found the magnetic susceptibility to be 7×10^{-6} to 25×10^{-6} mass unit; F. Merck and E. Wedekind gave 7.95×10^{-6} mass unit for $\text{Co}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, and zero for $\text{Co}_2\text{O}_3 \cdot \text{H}_2\text{O}$; and P. Hausknecht gave 2.7×10^{-6} mass unit for $2\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$. S. Veil found that the mol. coeff. of magnetization rises to a maximum as the cobaltic hydroxide is repeatedly re-dissolved and re-precipitated, or treated with hot water; F. Merck and E. Wedekind studied the change in the magnetic susceptibility which occurs on heating different preparations of the hydrated oxide.

FIG. 74.—Dehydration Curve of Hydrated Cobaltic Oxide.

A. F. Benton observed that **helium** is not absorbed by the hydroxide; but at -79° a gram of the oxide absorbs 0.325 c.c. of **hydrogen** at n.p. θ . H. Moissan observed that when hydrated cobaltic oxide is heated in hydrogen, it loses water between 100° and 200° , and reduction to cobalt begins at about 250° . C. R. A. Wright and A. P. Luff said that the reduction begins at 110° . A. F. Benton found that 0.325 vol. of hydrogen at n.p. θ is absorbed by cobaltic oxide at -79° ; and of **oxygen**, 0.264 at 0° ; 0.116 at 56.5° ; and 0.073 at 110° . G. Schröder found that oxygen at a red-heat has no action on cobaltic oxide. A. Coehn and M. Gläser, C. F. Cross, and G. Natta and M. Strada noted the great hygroscopicity of the hydrated oxide in **air**. E. Saint-Evre observed that the hydroxide is slightly soluble in hot **water**; and at 20° , G. Almkvist found that water containing carbon dioxide dissolves 3.18 mgrms. per litre. F. G. Tryhorn and G. Jessop studied the action of the colloid on **hydrogen dioxide**. Observations on the effect of acids have been made by W. Beetz, M. le Blanc and J. E. Möbius, C. D. Braun, A. Coehn and M. Gläser, E. Donath, E. Donath and J. Mayrhofer, W. Hempel and H. Thiele, E. Hüttner, F. Mawrow, S. W. Parr, J. L. Proust, A. Remelé, J. B. Rogojsky, E. Saint-Evre, F. W. Skirrow, F. G. Tryhorn and G. Jessop, W. Wernicke, and G. C. Winkelblech. The hydrated oxide is readily dissolved by **hydrofluoric acid**. As indicated by J. L. Proust, the hydrates dissolve in hot **hydrochloric acid**, with the evolution of chlorine; and G. C. Winkelblech noted that the hydrate dissolves in cold hydrochloric acid in the dark, but on exposure to light, or heat, chlorine gas is evolved and cobaltous chloride is formed. G. C. Winkelblech observed that when the hydrated oxide is warmed with a **hypochlorite**, oxygen is evolved. O. R. Howell studied the reaction. The hydrate is dissolved by **hydriodic acid** with the separation of iodine; and G. C. Winkelblech found that it forms a reddish-yellow liquid with a soln. of **sodium iodide**. J. L. Proust said that cobaltic oxide dissolves in **sulphurous acid**, with the formation of cobaltous sulphate. A. Geuther found that the freshly-precipitated hydrate dissolves in a warm soln. of **ammonium**

sulphite, with the evolution of ammonia, and the formation of a soln. of cobalt-ammine; and similarly with soln. of **potassium or sodium sulphite**. S. R. Benedict said that soln. of potassium **hydrosulphate** reduce the oxide. J. L. Proust also observed that the hydrate dissolves in warm **sulphuric acid**, with the evolution of oxygen. G. C. Winkelblech observed that in the dark, the oxide may be dissolved in cold sulphuric acid, but on exposure to light or heat, decomposition occurs, with the evolution of oxygen and the formation of a soln. of cobaltous sulphate. J. L. Proust, and G. C. Winkelblech observed that hydrated cobaltic oxide is not decomposed by aq. **ammonia**, even when warmed, and dissolution occurs only in the presence of a piece of tin. The resulting liquid is red. E. Donath and J. Mayrhofer, E. Fleischer, E. Hüttner, H. Rose, L. J. Thénard, T. Vorster, and G. C. Winkelblech said that the hydroxide is insoluble in aq. ammonia; on the other hand, O. W. Gibbs and F. A. Genth, and H. Remmler said that the hydrate is soluble in aq. ammonia—*vide infra*, aminohydroxides. T. Vorster found that the hydrate is not changed when it is heated with aq. or alcoholic ammonia in a sealed tube, or heated in the dry gas, at 170°. E. Donath and J. Mayrhofer observed that the hydroxide is insoluble in an aq. soln. of **ammonium chloride**, but if ammonia is added and the mixture is warmed, C. D. Braun said that the hydrated oxide dissolves; and E. J. Mills, and O. W. Gibbs and F. A. Genth observed that in a sealed tube at 70°, amines are formed. A. Geuther noted that the hydrated oxide dissolves slowly in a soln. of **ammonium sulphite** in the cold, and if heated, an ammine is formed. J. Mai and M. Silberberg said that hydrated cobaltic oxide is more stable towards **hydroxylamine** than is the case with nickelic oxide. A. Geuther observed that a neutral soln. of **potassium nitrite** does not change hydrated cobaltic oxide, but if a few drops of acid are added, yellow potassium cobaltic nitrite is formed. J. L. Proust observed that the hydrated oxide dissolves in fuming **nitric acid**, forming cobaltous nitrate, and it dissolves in warm nitric acid, with the evolution of oxygen. G. C. Winkelblech said that the dissolution of the hydrate in cold nitric acid in the dark is slow, and on exposure to light or heat, oxygen is evolved; and a similar observation was made with respect to **phosphoric acid**. G. C. Winkelblech said that with soln. of **alkali phosphate**, a brown precipitate is formed. C. Reichard found that a soln. of **arsenic trioxide** in soda-lye turns hydrated cobaltic oxide yellowish-brown in the cold, and when heated, greyish-brown, and finally dark blue; an ammoniacal soln. of arsenic trioxide reduces hydrated cobaltic oxide, and similarly with an aq. soln. G. C. Winkelblech said that with soln. of **alkali arsenite**, a brown precipitate is formed. With alkali oxalate, G. C. Winkelblech observed that a green soln. is formed; and F. Kehrmann, that in the presence of free acid, a complex salt is produced. C. R. A. Wright and A. P. Luff observed that **carbon** begins to reduce the hydrated oxide at 260°, and **carbon monoxide**, at -11°. F. Merck and E. Wedekind found that whilst hydrated cobaltic oxide—presumably $\text{Co}_3\text{O}_4 + \text{CoO}(\text{OH})$ —is almost inert in the catalytic oxidation of carbon monoxide at ordinary temp., the oxide is activated by the addition of manganese dioxide, and they examined the magnetic properties of the mixtures. A. F. Benton found that a gram of oxide at -79° absorbs 6 c.c. of carbon monoxide. C. J. Engelder and M. Blumer studied the catalytic activity of mixtures of cobaltic and ferric oxides in the oxidation of carbon monoxide. A. F. Benton observed that at 0°, 56.5°, and 100°, 1 gram of the oxide adsorbs, respectively, 10.21, 5.09, and 2.46 c.c. of **carbon dioxide**, at n.p. θ . W. P. Yant and C. O. Hawk studied the catalytic effect of the oxide on the oxidation of **methane**. A. Jorissen, and C. Reichard found hydrated cobaltic oxide does not dissolve in a soln. of **potassium cyanide**; but C. Krause, and E. Fleischer said that dissolution does take place. G. C. Winkelblech said that with soln. of **potassium ferrocyanide**, a dark red precipitate is formed. J. Mai and M. Silberberg observed that the hydrated oxide is more stable than nickelic oxide when in contact with **potassium or ammonium thiocyanate**. The solubility of the hydrated oxide in organic acids was studied by W. Beetz, M. le Blanc and J. E. Möbius, E. Fleischer, E. Hüttner,

F. Kehrmann, F. Mawrow, A. Remelé, E. Saint-Evre, A. Stromeyer, and G. C. Winkelblech. A. Remelé observed that conc. **acetic acid** dissolves hydrated cobaltic oxide without immediate decomposition, forming a brown soln.; and in oxalic acid, a green soln. is formed and carbon dioxide is evolved. G. C. Winkelblech observed that the hydrated oxide is soluble in **racemic, tartaric, oxalic, or citric acids**, forming cobaltous salts. N. Orloff observed that the soln. of hydrated cobaltic oxide in organic acids—*e.g.*, acetic or oxalic acid—soon decompose. A mixture of oxalic acid and ammonium acetate forms ammonium cobaltic oxalate. G. C. Winkelblech found that with a hot, aq. soln. of oxalic acid, cobaltous oxalate is formed, with the evolution of carbon dioxide; and if the moist, fresh hydrated oxide is heated with a soln. of **ammonium oxalate**, ammonia is evolved, and a green soln. of cobaltous oxalate is formed. A. H. Allen found that the hydrated oxide is stable in contact with **glycerol**; and E. Donath observed that freshly-precipitated hydrated cobaltic oxide is very slowly decomposed by a soln. of glycerol and soda-lye, or of glycerol, and ammonia, whilst with nickelic oxide under similar conditions a blue soln. is quickly formed, and the reaction can be utilized to detect cobalt in the presence of nickel.

H. Hess found that molten **potassium hydroxide** dissolves the hydrated oxide, forming an intense brown mass, but E. Hüttner said that the hydrated oxide is not attacked by alkali-lye. G. Schröder observed that with soln. of **manganese salts**, or of **ferric salts**, a basic salt is produced. P. Louyet, and E. Fischer found that with soln. of **ferrous salts**, the hydrated cobaltic oxide is reduced to cobaltous oxide, and hydrated ferric oxide is precipitated.

The salts of cobaltic oxide.—Cobaltic oxide is an amphoteric oxide, forming unstable salts with acids, and with bases. Solutions of the hydrated oxide in acids may not decompose immediately, and they then contain, presumably, **cobaltic salts**, but the soln. quickly decomposes, forming cobaltous salts with the evolution of oxygen. This was shown by G. C. Winkelblech to be the case with cold phosphoric, sulphuric, nitric, and hydrochloric acids, but best of all with cold acetic acid. W. Beetz, and N. Orloff also obtained similar results with acetic and oxalic acids. G. C. Winkelblech observed that the colour of a cobaltous salt appears darker if some cobaltic salt is present. The brown soln. of cobaltic acetate gives a brown precipitate with potassium hydroxide or carbonate, or with ammonium carbonate; the precipitation is incomplete with aq. ammonia—perhaps owing to the formation of an *ammonium cobaltite*, $(\text{NH}_4)_2\text{O} \cdot \text{Co}_2\text{O}_3$, or $(\text{NH}_4)\text{CoO}_2$. Sodium iodide gives a reddish-yellow soln., and alkali oxalates, a yellow soln. Hydrogen sulphide, and ammonium sulphide give black precipitates; alkali phosphates, and arsenates, brown precipitates; and potassium ferrocyanide gives a dark red precipitate—if the precipitant is in excess, potassium ferricyanide and green cobalt ferricyanide may be formed. The ferrocyanide precipitate was studied by C. D. Braun, and A. Remelé. For O. Feucht and G. Grube's, and G. Grube's observations on **potassium cobaltite**, K_2CoO_2 , *vide supra*, anodic behaviour of cobalt.

There is a series of compounds of the spinel type formed by the union of a bivalent metal oxide, which acts as a base, with oxide of a trivalent metal—*e.g.*, aluminium, chromium, and ferric iron—which acts as an acidic oxide, to form $\text{R}''\text{O} \cdot \text{R}_2''' \text{O}_3$, or $\text{R}''(\text{R}''' \text{O}_2)_2'$. Cobaltic oxide also forms analogous spinels. S. Holgersson and A. Karlsson prepared a series of **cobaltites** by evaporating to dryness mixed soln. of cobalt nitrate and a nitrate of the bivalent metal, and heating the mixture to 850° for $1\frac{1}{2}$ hrs.

W. G. Mixer was not able to isolate **sodium cobaltite**, $\text{Na}_2\text{O} \cdot \text{Co}_2\text{O}_3$, or NaCoO_2 , but he supposed that it is present in the product obtained by fusing cobalt oxide with an excess of sodium dioxide. The blue soln. of sodium cobaltite obtained by dissolving cobaltous oxide, or hydroxide, in conc. soda-lye, behaves just like a soln. of potassium cobaltite—*vide supra*, in connection with cobaltic oxide. R. Scholder and H. Weber prepared sodium cobaltite from solutions of cobalt nitrate and sodium hydroxide. The product was $\text{Na}_2[\text{Co}(\text{OH})_4]$, or $\text{Na}_2\text{CoO}_2 \cdot 2\text{H}_2\text{O}$.

A. C. Becquerel, I. Bellucci and F. Dominici, H. Hess, W. Mayer, L. Pebal, and A. Schwarzenberg noted the formation of **potassium cobaltite**, say in the ideal case, K_2CoO_2 , by melting potassium hydroxide with a cobalt salt. A. Schwarzenberg gave $\text{K}_2\text{O} \cdot 3\text{Co}_3\text{O}_5 \cdot 3\text{H}_2\text{O}$; L. Pebal, $\text{K}_2\text{O} \cdot 2\text{Co}_3\text{O}_5$; I. Bellucci and F. Dominici, $\text{K}_2\text{Co}_4\text{O}_8$; and W. Mayer added that the alkali is not present in stoichiometrical proportions. I. Bellucci and F. Dominici noted that the product is hydrolyzed by water, so that by repeated washing, A. H. McConnell and E. S. Hanes, and O. Brunck obtained cobaltous oxide, Co_3O_4 , as a residue. L. E. R. Dufau, and J. A. Hedvall observed no formation of a calcium cobaltite when mixtures of cobaltic and calcium oxides are heated together; and similarly with **strontium cobaltite**. R. Scholder and H. Weber also obtained $\text{Sr}_2[\text{Co}(\text{OH})_6]$. J. A. Hedvall and N. von Zweigbergk obtained **barium cobaltite** by the action of barium dioxide on cobalt oxide. G. Rousseau obtained crystalline products, $\text{BaO} \cdot 2\text{CoO}_2$, and $\text{BaO} \cdot \text{CoO}_2$ —*vide infra*, percobaltites. R. Scholder and H. Weber also obtained $\text{Ba}_2[\text{Co}(\text{OH})_6]$.

S. Holgersson and A. Karlsson obtained **copper cobaltite**, $\text{Cu}(\text{CoO}_2)_2$. The X-radiograms show that the spinel lattice has 8 mols. per unit cell, and that the edge of unit cell is 8.039 Å., and the sp. gr. 6.28. It showed no ferromagnetism. The corresponding **magnesium cobaltite**, $\text{Mg}(\text{CoO}_2)_2$, has a spinel lattice with edge 8.107 Å., and sp. gr. 4.96. It shows no ferromagnetic properties. J. A. Hedvall, S. Holgersson and A. Karlsson, L. Passerini, G. Natta and L. Passerini, and L. E. R. Dufau, H. J. Witteveen and E. F. Farnau also prepared this salt.

G. Natta and M. Strada prepared **zinc cobaltite**, $\text{ZnO} \cdot \text{Co}_2\text{O}_3$, or $\text{Zn}(\text{CoO}_2)_2$, by evaporating a soln. of mixed zinc and cobalt nitrates to dryness, and calcining the product at 800° . G. Natta and L. Passerini found that cobaltous and zinc oxide form solid soln. at temp. exceeding 1000° , but below that temp., in an oxidizing atm., zinc cobaltite, $\text{Zn}(\text{CoO}_2)_2$, is formed. It was studied by J. A. Hedvall and co-workers, and G. Natta and co-workers, and S. Holgersson and co-workers—*vide supra*, Rinman's green, cobaltous and zinc oxides. S. Holgersson and A. Karlsson gave for the zinc cobaltite lattice $a=8.108$ Å., and the sp. gr. 5.94. G. Natta and M. Strada gave $a=8.06$ Å., and sp. gr. 6.11. The salt showed no ferromagnetism. S. Holgersson and A. Karlsson also prepared a **manganous cobaltite**, $\text{Mn}(\text{CoO}_2)_2$, but in which some cobalt took the place of bivalent manganese, and some manganese in place of trivalent cobalt. The lattice constant is of the spinel type with $a=8.268$ Å. It did not exhibit ferromagnetism. A. Serres measured the magnetic susceptibility between -182.7° and 549.4° ; the Curie point is -164.5° ; the Curie constant, 4.261; and the magnetic moment for quadrivalent cobalt, 29. The cobaltites are isomorphous with cobaltous oxide, which can accordingly be regarded as **cobaltous cobaltite**, $\text{Co}(\text{CoO}_2)_2$. The cubic lattice of this salt is of the spinel type with the parameter $a=8.06$ Å. The calculated density is 6.27. S. Holgersson and A. Karlsson gave $a=8.108$ Å., and S. Holgersson, $a=8.110$ Å. The corresponding **nickel cobaltite**, $\text{Ni}(\text{CoO}_2)_2$, has a cubic lattice of the sodium chloride type, with $a=8.112$ Å. Bivalent cobalt may replace some of the nickel, and trivalent nickel, some of the cobalt. The compound is strongly ferromagnetic.

The cobaltic aminohydroxides.—E. Frémy² obtained an aq. soln. of **cobaltic hexaminohydroxide**, $[\text{Co}(\text{NH}_3)_6](\text{OH})_3$, by the action of barium hydroxide on a soln. of the sulphate. O. W. Gibbs and F. A. Genth, and L. Jacobsen prepared the compound by similar processes. The compound cannot be isolated by evaporating the yellowish-brown liquid, since decomposition with the evolution of ammonia sets in. A. B. Lamb and co-workers gave for the molecular conductivity, μ , and percentage ionization, α , of soln. with C mols. per litre at 0° and 25° :

	0°				25°			
	C	μ	α		C	μ	α	
	33.23	6.662	1.336	0.2678	33.23	6.662	1.336	0.2678
	347.5	396.9	431.1	469.0	591.3	675.3	739.0	843.0
	72.2	82.4	89.5	97.4	65.5	74.8	81.8	93.4

S. M. Jørgensen prepared **cobaltic trisethylenediaminehydroxide**, $[\text{Co en}_3](\text{OH})_3$, where en is employed for $\text{C}_2\text{H}_4(\text{NH}_2)_2$. The compound is obtained by shaking freshly-precipitated silver oxide with the corresponding chloride, and evaporating the soln., finally, over sulphuric acid. The dark yellow mass of deliquescent crystals furnishes an orange-yellow liquid. A. B. Lamb and co-workers measured the mol. conductivity, and found for soln. with 33.29 and 0.2683 mol. per litre, the respective conductivities 304.2 and 706.8 at 0° , and 394.4 and 519.1 at 25° ; the corresponding percentage degrees of ionization are 67 and 93 at 0° , and 66.4 and 90.4 at 25° . P. Pfeiffer and T. Gassmann obtained **cobaltic trispropylenediaminehydroxide**, $[\text{Co pn}_3](\text{OH})_3$, in aq. soln. by shaking the iodide of the series with freshly-precipitated silver oxide in water. The hydroxide was not isolated. Similarly also with **cobaltic ethylenediaminebispropylenediaminehydroxide**, $[\text{Co en}_2\text{pn}](\text{OH})_3$.

O. W. Gibbs and F. A. Genth obtained **cobaltic aquopentamminohydroxide**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{OH})_3$, by treating a soln. of the chloride of the series with silver oxide, or the sulphate with barium hydroxide. The compound is known only in aq. soln. S. M. Jørgensen prepared it by treating chloropentamminochloride with silver oxide, or chloropentamminosulphate with barium hydroxide. N. R. Dhar used a similar process. A. B. Lamb and co-workers measured the mol. conductivity, μ , of aq. soln. of C mols. of the compound per litre, and calculated α , the percentage ionization on the assumption that the complex contains H_2O , and α' , for the assumption that the complex contains OH :

$C \times 10^3$	33.21	6.66	1.335	0.2683
μ	223.4	244.7	261.8	286.8
α	45.7	55.0	53.5	58.6
α'	70.8	77.9	82.9	92.7

at the limit $\mu_\infty = 296$ at 0° . They inferred that the compound is more likely to be a hydroxypentammine than an aquopentammine. H. J. S. King also studied this compound. A. B. Lamb and co-workers, and H. J. S. King obtained a soln. of **cobaltic diaquotetramminohydroxide**, $[\text{Co}(\text{H}_2\text{O})_2(\text{NH}_3)_4](\text{OH})_3$, but not the solid. The mol. conductivity, μ , at 0° , and the percentage ionization, α , on the assumption that the complex contains $2\text{H}_2\text{O}$ -groups, and α' , on the assumption that it contains 2OH -groups, for soln. with C mols. per litre, are:

$C \times 10^3$	6.59	1.321	0.265
μ	116.4	115.4	102.7
α	24.8	24.5	21.8
α'	74.7	74.0	65.9

where at the limit $\mu = 469.0$ at 0° for the aquo-complex, and 154.0 for the hydroxide complex. The results favour the assumption that the compound is not a diaquotetrammine, but a hydroxytetrammine.

A. B. Lamb and co-workers found that **cobaltic diaquobisethylene diaminehydroxide**, $[\text{Co en}_2(\text{H}_2\text{O})_2](\text{OH})_3$, is stable only in aq. soln., and that the mol. conductivity, μ , of soln. with C mols per litre, and the percentage ionization calculated α on the assumption that the complex contains $2\text{H}_2\text{O}$ -groups, and α' on the assumption that it contains 2OH -groups, are:

$C \times 10^3$	33.2	6.674	1.338	0.2683
μ at 25°	185.0	197.4	209.0	269.4
α at 25°	22.7	25.2	26.7	34.5
μ at 0°	107.6	113.9	116.8	143.1
α at 0°	24.6	26.6	27.3	33.4
α'	73.7	79.8	81.8	100.3

where the limiting value of $\mu = 430$ at 0° on the assumption that 2HO -groups are present in the complex ion, and 115.0 on the assumption that the complex ion contains $2\text{H}_2\text{O}$ -groups. The results favour the assumption that the compound is a dihydroxy-salt not a diaquo-salt. The subject was discussed by H. J. S. King.

P. Job prepared a soln. of **cobaltic hydroxypentamminohydroxide**, $[\text{Co}(\text{NH}_3)_5(\text{OH})](\text{OH})_2$, by treating the corresponding sulphate with the theoretical

proportion of barium hydroxide. The hydroxide is not precipitated by alcohol.

A. Job, and H. J. S. King prepared **cobaltic dihydroxytetramminohydroxide**, $[\text{Co}(\text{NH}_3)_4(\text{OH})_2](\text{OH})$, and found for the eq. conductivity, λ , at 0° , of soln. with an eq. of the salt in v litres :

v	31.23	65.96	125.0	263.8	511.0	1002	∞
λ	118.0	120.6	122.2	123.6	123.0	116.6	126.6

§ 13. The Higher Oxides of Cobalt—Cobalt Dioxide

G. C. Winkelblech,¹ E. Frémy, O. Brunck, G. Schröder, and G. Natta and M. Strada were not able to prepare **cobalt dioxide**, CoO_2 , in the dry way; and J. A. Hedvall and N. von Zweigbergk noted the formation of a peroxide when cobalt oxide is heated with barium dioxide. The dioxide appears associated with more or less cobaltous oxide, so that the various oxides between cobaltic oxide, Co_2O_3 , or possibly cobaltous oxide, CoO , and cobalt dioxide, CoO_2 , which have been reported, are probably mixtures or solid soln. of cobaltous oxide and cobalt dioxide. Indeed, cobaltic oxide, as reported in some cases, may be a mixture of the two oxides, $\text{CoO} \cdot \text{CoO}_2$, or possibly *cobaltous percobaltite*, $\text{Co}(\text{CoO}_3)$. The methods employed for preparing the dioxide have a marked influence on the composition of the final product. In some cases the oxide, $m\text{CoO} \cdot n\text{CoO}_2$, actually obtained, probably represents an arrested reaction (**4**, 31, 33), an accidental stage in the degradation of cobalt dioxide to cobaltous oxide. Our knowledge of the higher oxides of cobalt is not in a satisfactory state. A. Quartaroli inferred the existence of higher oxides from measurements of the magnetic susceptibilities of the oxidized products. R. Bernard and P. Job believed that the dioxide is formed as an intermediate stage in the oxidation of cobaltous to cobaltic oxide.

E. Hüttner observed that when cobalt sulphate is oxidized by potassium persulphate in acidic or alkaline soln., by ammonium persulphate in alkaline soln., by chlorine gas, or by anodic chlorine from a soln. of cobalt sulphate containing a large excess of potassium chloride, the product always approximates to cobaltic oxide, Co_2O_3 , but by the direct application of hypochlorites, a higher oxide can be obtained. Thus, J. Thomsen prepared a hydrate approximately Co_3O_5 , or $\text{CoO}_{1.70}$, by the action of equimolar parts of sodium hypochlorite and cobaltous chloride, and if the action be allowed to continue for a long time, the product approximates Co_3O_7 , or $\text{CoO}_{1.75}$. T. Bayley obtained, in an analogous manner, a precipitate approximating Co_3O_5 , and with hot soln., the product had rather less oxygen, $\text{Co}_{12}\text{O}_{19}$, or $\text{CoO}_{1.6}$; using boiling soln., G. Schröder obtained $\text{Co}_5\text{O}_8 \cdot 11\text{H}_2\text{O}$, that is, hydrated $\text{CoO}_{1.6}$. A. Carnot, with hypochlorites in alkaline soln., obtained oxides ranging from $\text{CoO}_{1.60}$ to $\text{CoO}_{1.625}$; and E. Hüttner, using a dil. soln. of a cobalt salt and an excess of oxidizing agent, found that the product fell from $\text{CoO}_{1.6}$ to $\text{CoO}_{1.575}$. Analogous oxidation products, exceeding Co_2O_3 , were obtained by C. Krause, O. R. Howell, H. McLeod, E. Fleischer, G. Schröder, O. Popp, T. Bayley, R. Fischer, G. Vortmann, and A. Metzl, with a hypochlorite as oxidizing agent. The existence of a hypothetical acid, H_2CoO_3 , was assumed by H. Copaux, R. G. Durrant, A. Job, A. H. McConnell and E. S. Hanes, and C. Winkler.

O. R. Howell studied the action of hypochlorites on soln. of cobalt sulphate, and

found that hypochlorites free from alkali immediately precipitate from aq. soln. of cobalt sulphate a slightly peroxidized cobalt sesquioxide of constant composition; but since the peroxide catalytically decomposes the hypochlorite, the precipitation is far from quantitative. When less than half an eq. of hypochlorite is used with an excess of alkali, more available oxygen is found in the precipitate than was used in the hypochlorite; this is attributed to atm. oxidation of the precipitated hydroxide. A higher degree of oxidation is reached with hypochlorite and alkali than with hypochlorite alone. This is attributed to the formation of a hydroxylated peroxide, by the direct oxidation of cobaltous hydroxide. The temp. has no important influence on the composition of the precipitate. The oxide is very stable, since it can be kept indefinitely, and prolonged boiling causes no loss of available oxygen. The concentration of the reacting solutions likewise has practically no influence on the composition of the precipitate.

A fully-oxidized precipitate was obtained by precipitating cobalt sulphate with sodium hydroxide and hypochlorite, using 1.5 eq. of alkali hydroxide per eq. of hypochlorite; when the decomposition of the excess of hypochlorite was complete, another eq. was added; and after the decomposition of this, another 0.5 eq. was added. The precipitate was allowed to settle, washed by decantation three times, filtered and washed on a Buchner funnel until the filtrate was almost free from alkali. The deposit was then shaken up with water and allowed to stand in contact with water 3 months before use.

O. R. Howell compared the oxidation of nickel and cobalt salts by hypochlorites, and found that the peroxidized precipitate obtained with cobalt is stable; it can be kept for a long time, or the suspension boiled without loss of oxygen. With nickel, the precipitate decomposes with evolution of oxygen even in suspension at the ordinary temperature, and the oxygen content falls continuously below that corresponding to the sesquioxide; decomposition is accelerated by heat and retarded by alkali. Hypochlorites free from alkali react immediately with cobalt solutions, yielding a peroxidized precipitate, the rate of the reaction being comparable with that of precipitation of the hydroxide by alkali and its oxidation by hypochlorite. With nickel, the action is delayed and is negligibly slow compared with the action in the presence of alkali. In the presence of alkali, the hydroxides are peroxidized. With cobalt, excess of hypochlorite causes a decrease in the oxygen-content owing to its further oxidizing action. With cobalt, excess of alkali causes a small increase in the oxygen-content owing to increased precipitation as hydroxide; with nickel, it causes a large increase owing to its retarding decomposition of the precipitate. Precipitated with sodium carbonate and hypochlorite, cobalt salts yield a peroxidized carbonate; in the case of nickel, however, the precipitated carbonate is oxidized to the peroxide with a loss of carbon dioxide, which yields the bicarbonate.

R. Fischer oxidized cobalt salts with bromine in the presence of an alkali, and obtained products similar to those obtained with the hypochlorites. Analogous results were obtained by E. Fleischer, A. Carnot, E. Donath and J. Mayrhofer, and R. Fischer, by using iodine or bromine as oxidizing agent in alkaline soln. G. Vortmann oxidized a soln. of cobalt sulphate with iodine and alkali-lye, and obtained products ranging from $\text{CoO}_{1.7}$ to $\text{CoO}_{1.8}$. E. Hüttner observed that when an alkaline soln. of potassium cobalt sulphate is oxidized with an excess of iodine, the black precipitate approximates closely to CoO_2 . If less iodine be employed, a less highly-oxidized product is obtained. A. Metzl observed that cobalt dioxide can be prepared by mixing cobalt sulphate, iodine, and alkali-lye, washing the precipitate by decantation, and filtering through asbestos in order to avoid reduction by the filter-paper. The same compound was obtained by using silver nitrate and alkali-lye as oxidizing agent, as did H. Rose, in 1857. The silver which is precipitated—possibly as $\text{Ag}_4\text{O} \cdot \text{Co}_2\text{O}_3$ (H. Rose)—can be removed by washing with permanganate and nitric acid.

C. Tubandt oxidized a blue soln. of cobaltous hydroxide in potash-lye, using a porous diaphragm, and obtained about the anode, a bluish-black oxide approxi-

inating $\text{CoO}_{1.6}$. The anodic oxidation of cobalt in potash-lye at high current-densities was shown by G. Grube and O. Feucht, A. Coehn and E. Salomon, H. N. Holmes, N. Isgarischeff, and E. Müller and F. Spitzer to furnish a solid soln. of cobalt dioxide in one of the lower oxides—*vide supra*, hydrated cobaltic oxide. K. A. Hofmann and H. Hiendlmaier fused cobaltous oxide with potassium dioxide, washed the product with water for several days, digested it with cold, 10 per cent. sulphuric acid, again washed the product with water, and then dried it over phosphorus pentoxide. The tabular crystals had a composition corresponding with $\text{Co}_3\text{O}_5 \cdot 2\text{H}_2\text{O}$, or hydrated $\text{CoO}_{1.67}$. A. H. McConnell and E. S. Hanes said that the *monohydrate*, $\text{CoO}_2 \cdot \text{H}_2\text{O}$, or H_2CoO_3 , is formed by the action of hydrogen dioxide on cobaltous hydroxide suspended in water, but R. G. Durrant could not confirm this. A. Metzl observed that the oxidation of a cobalt salt soln. by hydrogen dioxide and sodium hydrocarbonate furnishes a green precipitate, which, when analyzed in the moist state, has the composition $\text{Co}_2\text{O}_3 \cdot \text{CoCO}_3$, or $\text{Co}(\text{CoO}_3) \cdot \text{CoCO}_3$. B. Brauner used potassium permanganate as oxidizing agent; D. Bhaduri and P. Ray, potassium ferricyanide; and F. Fichter and A. R. y Miro, potassium perphosphate.

G. Schröder obtained a colloidal soln. of Co_3O_5 by digesting the freshly-precipitated oxide with nitric acid for some days, and then washing with water. The precipitate is peptized, and a clear, dark brown soln. is formed. The sol. coagulates and becomes turbid after standing for 10 days. The sol. is also coagulated by the addition of alkali salts.

The product obtained by precipitation methods is usually black; that obtained by K. A. Hofmann and H. Hiendlmaier appeared in 6-sided plates, sometimes arranged in rosettes. S. Veil studied the magnetic properties of cobalt hydroxide which had been treated with hydrogen dioxide. The general properties of these oxides resemble those of hydrated cobaltic oxide. With hydrochloric acid, chlorine is given off, and with sulphuric acid, oxygen. According to O. R. Howell, the rate of decomposition of sodium hypochlorite by cobalt peroxide has been investigated at 25° and 50° under various conditions. It has shown that the rate of decomposition is directly proportional to the quantity of cobalt peroxide present. The rate of decomposition is accelerated by the presence of sodium salts; in the case of sodium chloride it is directly proportional to the square root of the concentration of sodium-ions present. This is explained by assuming the mechanism of the reaction to consist in the linking of hypochlorite-ions to the positive oxygen, and sodium-ions to the negative oxygen of the peroxide, with subsequent immediate decomposition of the quadrivalent oxygen compound. In the presence of a fixed amount of hypochlorite, the rate is then proportional to the degree of adsorption of the sodium-ions. The rate is retarded by alkali, and the retardation is proportional to the adsorption of hydroxyl-ions. This is attributed to the hydroxyl-ions being attracted by the positive oxygen of the peroxide, yielding an inactive compound to the exclusion of hypochlorite-ions. The average temp. coeff. of the reaction between 25° and 50° is 2.37. The catalyst is not "poisoned" by hydrogen sulphide, potassium cyanide, mercuric chloride, or arsenic trioxide. E. Chirnoaga

represented the reaction by $-dC/dt = kC^n$, where C denotes the concentration of the hypochlorite; n is a constant; and k is proportional to the surface area of the catalyst. The order of activity of the oxides is $\text{Ni} > \text{Co} > \text{Cu} > \text{Fe} > \text{Mn} > \text{Hg}$. C. R. A. Wright and A. P. Luff found that the reduction with hydrogen begins at about 110° ; but with carbon, at 260° ; and with carbon monoxide, at -11° . T. Bayley said that the product Co_3O_5 is stable at a dull red-heat. H. A. J. Pieters found that mixtures of carbon monoxide and air begin to oxidize at 40° in the presence of cobalt dioxide.

Percobaltities.—A. Schwarzenberg observed that when potassium hydroxide is fused in air with cobaltous or cobaltous oxide, or cobaltous carbonate, at a high temp., crystals are formed which can be separated by washing away the excess of alkali. A similar product was obtained by E. Becquerel, and L. Pebal. W. Mayer

obtained it by mixing some chlorate or nitrate with the potassium hydroxide. According to L. Pebal, the black, thin, 6-sided plates have a metallic lustre not unlike a ferruginous mica. They do not react alkaline to litmus. When dried at 100° , they do not lose weight when heated to 200° . A. Schwarzenberg, and W. Mayer observed that the crystals react alkaline after being strongly heated, and they then give up potassium hydroxide when extracted with water, and cobaltous oxide remains. They lose alkali slowly when treated for a long time with cold water, and rapidly when treated with boiling water. Cold, dil. hydrochloric acid extracts very little alkali, and has no appreciable solvent action, but with conc. hydrochloric acid, the salt dissolves with the evolution of chlorine. The salt is dissolved by other conc. acids; with dil. nitric acid, cobaltous oxide passes into soln. and oxygen is evolved.

L. Pebal assigned to this product a formula $K_2O \cdot 2Co_3O_5$, but A. Schwarzenberg, and W. Mayer gave $K_2O \cdot Co_9O_{15} \cdot 3H_2O$, or $K_2O \cdot 3Co_3O_5 \cdot 3H_2O$. I. Bellucci and F. Dominici considered that a mistake was made owing to the contamination of the products with silver due to the attack of the silver crucibles by the fused potassium hydroxide, and to the hydrolysis of the compound when it was washed with water. They said that the black, shining, hexagonal plates are really **potassium cobaltous percobaltite**, $K_2O \cdot CoO \cdot 3CoO_2$; and added:

The best method of preparing the cobaltous potassium cobaltite in a pure state is to fill a nickel crucible with alternate layers of potassium hydroxide and of either cobaltous carbonate or any oxide of cobalt, and to fuse the mass by gently heating it, afterwards heating more strongly with a Bunsen flame for 3 hours. After cooling in a dry vacuum, the mass is introduced into 12 per cent. potassium hydroxide soln. well cooled with ice. The alkali is renewed several times, the crystals being filtered off by means of a pump, washed repeatedly with alcohol, and dried.

The slender, hexagonal plates so obtained have a steel-grey lustre and they are rapidly hydrolyzed by water. The 6-sided plates of $Co_3O_5 \cdot 2H_2O$, obtained by K. A. Hofmann and H. Hiendlmaier, were probably produced by the hydrolysis of potassium cobaltous percobaltite. W. G. Mixer obtained **sodium percobaltite**, Na_2CoO_3 , by fusing cobalt oxide with sodium dioxide, and he found the heat of formation $(CoO_2, Na_2O) = 100.2$ Cals.

G. Rousseau prepared **barium perdicobaltite**, $BaO \cdot 2CoO_2$, by heating to redness, in an open platinum crucible, a mixture of 15 grms. of hydrated barium chloride or bromide and 5 to 6 grms. of powdered barium oxide, then adding a gram of cobaltic oxide in small quantities at a time. Each addition of the cobaltic oxide is attended by the evolution of oxygen, but the mixture soon enters into quiet fusion. The cold product is lixiviated with water and, finally, acetic acid. The shining, black, hexagonal plates dissolve in conc. hydrochloric acid with evolution of chlorine. The quantity of crystals formed, at first increases, but afterwards diminishes owing to decomposition which is accompanied by slow evolution of oxygen. After prolonged heating, crystals of cobalt oxide are obtained, which are free from barium. If, however, the superficial layer of crystals is continually pressed down into the fused mass beneath, the proportion of barium oxide in the product increases, and the composition of the crystals approximates to **barium percobaltite**, $BaO \cdot CoO_2$, or $Ba(CoO_3)$. If the fusion is conducted at a higher temp., large, iridescent, black prisms of barium percobaltite are formed and they always contain a small proportion of barium platinate as an impurity. They dissolve in cold hydrochloric acid with evolution of chlorine, and in nitric acid with effervescence. The crystals decompose at a temperature somewhat higher than that at which they are formed, and at an orange-red heat decomposition is very rapid. The temp. of formation of the normal cobaltite lies between 1000° and 1100° . A somewhat similar phenomenon has already been observed in the case of barium and strontium permanganites, but in these instances the normal manganite was formed at the lower temp., and the acid permanganite at a higher temp. L. E. R. Dufau could not prepare **strontium percobaltite**, or **calcium percobaltite**,

by heating the respective oxides with cobalt in an electric-arc furnace, as in the case of magnesium percobaltite—*vide supra*, cobaltites.

According to J. J. Berzelius, magnesia, or magnesian minerals—free from alumina, or a heavy metal oxide—take on a pale rose-colour when ignited with cobalt nitrate. When ammonia is added to a mixture of neutral magnesium and cobaltous chlorides, a green precipitate is formed. The precipitate does not turn brown during the subsequent washing; it is insoluble in aq. ammonia and ammonium carbonate, but it readily forms a yellow liquid when treated with a soln. of ammonium chloride, and it is again precipitated from the yellow soln. by the addition of potassium hydroxide. The green product becomes greyish-black when ignited. According to L. E. R. Dufau, when an intimate mixture of 150 grms. of cobaltic oxide and 75 grms. of magnesium oxide is heated for 10 mins. in an electric-arc furnace, **magnesium percobaltite**, $\text{MgO} \cdot \text{CoO}_2$, or $\text{Mg}(\text{CoO}_3)$, is obtained as a very deep, garnet-red, crystalline mass of sp. gr. 5.06 at 20° . Its hardness is between 4 and 5. The cobaltite is dissolved by hydrofluoric acid, by hydrochloric acid with evolution of chlorine, and by nitric and sulphuric acids with evolution of gas, and it is also decomposed and partially dissolved by ammonia. Oxygen is without action on it at a red-heat, but sulphur converts it into cobalt sulphide at a lower temp. Chlorine attacks it with production of cobaltous chloride, which sublimes, and bromine behaves similarly, but iodine seems to have no action. Dry hydrogen fluoride and dry hydrogen chloride also decompose it readily, but fused oxidizing agents have no action on it. A. Serres discussed the magnetic susceptibility, and the magnetic moment. The Curie constant is 4.261, and the Curie temp., 164.5°K .

The so-called *Rinman's green*,² *zinc green*, or *cobalt green*, obtained by calcining a mixture of cobalt and zinc oxides, may contain some **zinc percobaltite**. Cobaltic oxide, Co_2O_3 , is sometimes considered to be **cobaltous percobaltite**, $\text{Co}(\text{CoO}_3)$, and the compound, Co_3O_5 , to be **cobaltous perdicobaltite**, $\text{CoO} \cdot 2\text{CoO}_2$. T. Bayley³ described the *monohydrate*, $\text{Co}_3\text{O}_5 \cdot \text{H}_2\text{O}$; K. A. Hofmann and H. Hiendlmaier, the *dihydrate*, $\text{Co}_3\text{O}_5 \cdot 2\text{H}_2\text{O}$; and T. Bayley, the *trihydrate*, $\text{Co}_3\text{O}_5 \cdot 3\text{H}_2\text{O}$, and the *tetrahydrate*, $\text{Co}_3\text{O}_5 \cdot 4\text{H}_2\text{O}$.

§ 14. Cobalt Fluorides

O. Ruff and E. Ascher¹ observed that the action of fluorine on finely-divided cobalt begins at about 500°, and a mixture of cobaltous and cobaltic fluorides is formed; and if the product is heated in hydrogen at 200° to 300°, the cobaltic fluoride is reduced to **cobaltous fluoride**, CoF_2 . Other reducing agents act similarly. C. Poulenc prepared cobaltous fluoride by treating cobaltous chloride with gaseous hydrogen fluoride at ordinary temp.; E. Birk and W. Biltz, by heating the tetrahydrate in vacuo over sulphuric acid for 10 hrs. at 150°, and in vacuo over phosphorus pentoxide for 20 hrs. at 300°, finally, heating the product up to the softening temp. of glass. C. Poulenc observed that when cobaltous oxide or hydroxide is treated with hydrogen fluoride at 400° to 500°, it is converted into amorphous cobaltous fluoride, which becomes crystalline if the temp. is raised. C. Poulenc melted anhydrous cobalt chloride with an excess of ammonium fluoride, washing the cold product with alcohol, and heating to redness the resulting ammonium cobalt fluoride in a current of an indifferent gas, say, carbon dioxide. The pulverulent cobalt fluoride so obtained can be converted into a crystalline mass by melting it in a current of hydrogen fluoride. G. L. Clark and H. K. Buckner said that the oxide is formed by this process, but O. Ruff, and E. Birk and W. Biltz verified C. Poulenc's results. K. Jellinek and R. Koop purified the salt by mixing it intimately with ammonium fluoride, and heating the mixture at 400° to 500°, and subliming off the ammonium fluoride in a current of hydrogen fluoride containing a small proportion of hydrogen.

Cobaltous fluoride, according to C. Poulenc, furnishes rose-red, monoclinic prisms; but A. de Schulten said that the crystals are optically positive tetragonal prisms. O. R. Howell, A. Ferrari, and P. P. Ewald and C. Hermann said that the tetragonal crystals have the rutile type of lattice. The X-radiograms of the ruby-red crystals, measured by A. Ferrari, show that the space-lattice is tetragonal and of the rutile type, with the lattice dimensions $a=4.695$ Å., $c=3.193$ Å., and $a:c=1.0680$. The vol. of the lattice is 70.38×10^{-24} c.c. W. Zachariasen and V. M. Goldschmidt observed $a=4.70$ Å., and $c=3.18$ Å. The shortest distance between the cobalt and fluorine atoms is 2.04 Å. Observations were made by V. M. Goldschmidt, and J. W. Gruner. O. Ruff and E. Ascher calculated from the lattice constants the sp. gr. 4.55; and A. Ferrari, 4.574—C. Poulenc observed 4.43; and E. Birk and W. Biltz, and W. Biltz and E. Rahlfs, 4.460 at 25°/4°, for the sp. gr. E. Birk and W. Biltz calculated 21.74 for the mol. vol.; and G. L. Clark and H. K. Buckner gave 23.0, and showed that there is a 27.5 per cent. contraction in the formation of the compound from its elements. A. Rudat gave for the heats of formation, 160.7 Cals. at 300° to 500°; and for the press., p , of the

fluorine at 300°, 400°, 500°, and 600°, respectively, 3.55×10^{-54} , 2.45×10^{-45} , 9.33×10^{-39} , and 2.09×10^{-33} . C. Poulenc said that the salt melts between 1100° and 1200°—E. Birk and W. Biltz said over 1000°. K. Jellinek and R. Koop gave for the heat of formation $(\text{Co}_2\text{F}_2) = 160.7$ Cals.; E. Petersen, $(\text{Co}_2\text{F}_2, \text{Aq.}) = 125.4$ Cals.; H. von Wartenberg and O. Fitzner, $(\text{Co}_2\text{F}_2, \text{Aq.}) = 172.8$ Cals.; E. Petersen found the heat of neutralization of $\frac{1}{2}\text{Co}(\text{OH})_2$ by HFAq. to be 13.245 Cals. G. Beck studied the energy of the molecule. R. A. Houston and co-workers, and G. Denigès measured the absorption spectra of the red aq. soln.; and M. Kimura and M. Takewaki measured the ultra-violet absorption spectrum. N. Costachescu found the mol. conductivity of soln. with a mol of the salt in 100, 500, and 1000 litres to be, respectively, 158.7, 184.0, and 191.9 mhos. The tetrahydrate in aq. soln. is hydrolyzed. G. Gore obtained a black powder on the cathode on electrolyzing a soln. of cobalt fluoride in dil. hydrofluoric acid. O. Liebknecht and A. P. Wills found the mol. magnetic susceptibility of an aq. soln. to be $10,370 \times 10^{-6}$ mass unit when the sp. susceptibility for water at 18° is -0.75×10^{-6} mass unit. B. Cabrera and A. Duperier, and P. Henkel and W. Klemm measured the magnetic susceptibility of the anhydrous salt.

C. Poulenc observed that the reduction of cobaltous fluoride by hydrogen begins at a dull red-heat. K. Jellinek and co-workers studied the equilibrium $\text{CoF}_2 + \text{H}_2 \rightleftharpoons \text{Co} + 2\text{HF}$ approached from the hydrogen side, because of the slow rate of diffusion of hydrogen fluoride through the film of fluoride, first formed on the surface of the metal, when an approach is made from the other side. The equilibrium constants $K = P^2\text{HF}/p_{\text{H}_2}$ at 300°, 400°, 500°, and 600° are, respectively, 0.00029, 0.01096, 0.1698, and 2.754. O. Ruff found that the salt is stable in cold water; and C. Poulenc showed that the salt is rather more soluble in water than is the nickel salt, and with steam, at a dull red-heat, it is decomposed into hydrogen fluoride and cobaltous oxide. R. H. Carter found that 100 c.c. of a sat. soln. at 25° contained 1.415 grms. of CoF_2 .

J. L. Gay Lussac and L. J. Thénard evaporated a soln. of cobaltous carbonate in an excess of hydrofluoric acid, and obtained rose-red crystals which, according to J. J. Berzelius, are the *dihydrate*, $\text{CoF}_2 \cdot 2\text{H}_2\text{O}$. The dihydrate was also prepared by I. Tananajeff. G. L. Clark and H. K. Buckner reported the *trihydrate*, $\text{CoF}_2 \cdot 3\text{H}_2\text{O}$, to be formed in rose-red crystals from a soln. of cobalt carbonate in hydrofluoric acid. Its sp. gr. is 2.583; and it loses all its water of crystallization at 300°. E. Birk and W. Biltz could not confirm the trihydrate; they always obtained the tetrahydrate. N. Costachescu could not prepare the *hexahydrate*, $\text{CoF}_2 \cdot 6\text{H}_2\text{O}$, or $[\text{Co}(\text{H}_2\text{O})_6]\text{F}_2$, but he obtained the *tetrahydrate*, $\text{CoF}_2 \cdot 4\text{H}_2\text{O}$, or $[\text{Co}(\text{H}_2\text{O})_4]\text{F}_2$, in two isomeric forms. The α -form was obtained in large, garnet-red, rhombic octahedra by dissolving freshly-prepared cobalt hydroxide in 40 per cent. hydrofluoric acid, diluting the resulting solution with an equal volume of the acid, and allowing it to crystallize in a vacuum over conc. sulphuric acid. The β -salt is produced when the above solution is precipitated with 96 per cent. alcohol; it forms small, rose-coloured crystals, and is isomorphous with the corresponding nickel salt. The β -salt is more soluble in water (the saturated solution at room temp. is 2.3203 per cent., whilst that of the α -salt is 2.2328 per cent.) and hydrofluoric acid than the α -salt; it also loses water more readily, at 60° losing 37.10 per cent. H_2O , whilst the α -salt loses only 9.35 per cent., and is more reactive than the α -salt. Both salts give identical solutions in water, as shown by measurement of the electrical conductivity. It is probable that the solids are stereoisomerides, in the α -form the fluorine atoms being situated at the opposite ends of one of the axes of the octahedron, whilst in the β -form they are at the opposite ends of one of the sides. A. Kurtenacker and co-workers could not dehydrate the tetrahydrate without loss of fluorine. W. Biltz and E. Rahlfs gave 2.192 for the sp. gr. of the β -tetrahydrate at 25°/4°. J. J. Berzelius found that the hydrate dissolves without decomposition in cold water, and in water acidified with hydrofluoric acid, but with hot water, hydrolysis occurs, and a soluble basic salt is formed as

cobalt oxyfluoride, $2\text{CoO} \cdot 2\text{CoF}_2 \cdot \text{H}_2\text{O}$, and the same product appears when hydrofluoric acid is digested with an excess of cobalt carbonate. N. Costachescu also observed the hydrolysis of the salt in aq. soln., and he gave for the water solubility 1.33 per cent. CoF_2 at 20° ; R. H. Carter, 1.415 grms. CoF_2 in 100 c.c. water at 25° , and A. Kurtenacker gave 1.36 grms. of CoF_2 per 100 c.c. of solution at 20° . The salt is hydrolyzed at higher temperatures.

O. Ruff and E. Ascher said the bromine vapour has no perceptible action on cobaltous fluoride, and similarly with iodine. C. Poulenc said that the anhydrous salt is insoluble in hydrofluoric acid, but O. Ruff and E. Ascher observed that when the soln. in 40 per cent. hydrofluoric acid is evaporated, it furnishes soluble crystals of a hydrate. According to E. Böhm, an excess of hydrofluoric acid acts on cobaltous fluoride forming a soln., which, when evaporated over sulphuric acid, in vacuo, forms an oily liquid from which red, prismatic crystals of **cobalt hydrofluoride**, $\text{CoF}_2 \cdot 5\text{HF} \cdot 6\text{H}_2\text{O}$, are deposited. The crystals are isomorphous with the corresponding nickel salt (*q.v.*), and B. Gossner said that the crystals are trigonal, and have a sp. gr. of 2.086. The salt is stable if air be excluded, but it decomposes when heated. It is soluble in water, and dil. acid. N. Costachescu was unable to prepare this or the corresponding nickel salt. Observations on the hydrofluoride were also made by F. Fichter and H. Wolfmann, F. H. Edminster and H. C. Cooper, and E. Birk. A. Kurtenacker and co-workers found the solubility of cobalt fluoride in 3 per cent. hydrofluoric acid to be:

	20°	40°	50°	80°	90°	100°
CoF_2 . . .	3.35	3.48	3.60	3.90	4.61	5.43

The solid phase is $\text{CoF}_2 \cdot 4\text{H}_2\text{O}$; there is no break in the curve. The solubility increases rapidly with increasing concentrations of the acid, for, at 20° , 11.5 per cent. hydrofluoric acid dissolved 5.9 per cent. CoF_2 ; and 13.5 per cent. hydrofluoric acid, 9.6 per cent. CoF_2 . C. Poulenc observed that at a dull red-heat, hydrogen chloride forms cobaltous chloride; and at ordinary temp., hydrogen fluoride converts cobalt chloride to fluoride. K. Jellinek and R. Koop gave for the equilibrium constant $K = [\text{HF}]/[\text{HCl}]$ of the reaction $\text{CoF}_2 + 2\text{HCl} = \text{CoCl}_2 + 2\text{HF}$, 0.4 at 315° , and 0.73 at 532° , and for the thermal value of the reaction -5.19 Cals. According to C. Poulenc, conc. hydrochloric acid in the cold dissolves very little fluoride, but the salt is readily soluble in the hot acid. C. Poulenc found that when the fluoride is melted with sulphur, a black product is formed which gives off hydrogen sulphide when treated with hydrochloric acid. O. Ruff and E. Ascher observed that sulphur has very little action, though a trace of cobalt sulphide may be formed; at a red-heat, hydrogen sulphide forms cobalt sulphide; and O. Ruff and E. Ascher observed that the fluoride is darkened by sulphur dioxide at a red-heat. C. Poulenc found that conc. sulphuric acid attacks the salt very slowly in the cold, but rapidly when heated. O. Ruff and E. Ascher observed that when heated in ammonia, the salt is reduced to metal.

G. Gore found that the fluoride is insoluble in liquid ammonia; and when the salt is heated strongly in gaseous ammonia, O. Ruff and E. Ascher observed that metallic cobalt is formed. There is a general tendency for ammoniacal soln. of cobaltous salts to oxidize to cobaltic salts on exposure to air, and to form cobaltamines. The results depend to some extent on the nature of the anion. W. Biltz and co-workers attributed the inertness of the fluoride to a high lattice energy; this steric hindrance, as it is called, enables it to resist the entry of other molecules. They said that the anhydrous chloride does not react with gaseous ammonia nor yet with liquid ammonia at -78.5° , nor with ammonia under press. at room temp. It is, however, possible to prepare amines in which water is present, and where, it is supposed, the water is associated with the lattice. They were unable to confirm the report of G. L. Clark and H. K. Buckner that **cobaltous triamminofluoride**, $\text{Co}(\text{NH}_3)_3\text{F}_2$, is formed as a pink powder, when the hexamine is kept in dry air. It loses all its ammonia at 40° . Nor could they prepare **cobaltous hexamminofluoride**, $\text{Co}(\text{NH}_3)_6\text{F}_2$, reported by G. L. Clark and H. K. Buckner to

be formed by passing ammonia over dry cobalt fluoride, and allowing the reddish-brown liquid to solidify. Its sp. gr. is 1.744; and it dissolves in water without hydrolysis. The vap. press. of each ammine is said to be 100 mm. at 50°. E. Böhm also showed that the results with fluorides are exceptional, for when a soln. of cobalt hydroxide in hydrofluoric acid is treated with ammonia, and exposed to air for four weeks, a pale yellow crust of ammonium cobaltous fluoride, $(\text{NH}_4)_2\text{CoF}_4 \cdot 2\text{H}_2\text{O}$, was formed. W. Biltz and E. Rahlfs cooled in solid carbon dioxide a soln. of 6 grms. of tetrahydrated cobalt fluoride in 25 c.c. of conc. aq. ammonia, and mixed with 40 c.c. of alcohol freed from dissolved air by boiling. Rose-red crystals of **cobaltous aquopentamminofluoride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{F}_2$, are formed. The sp. gr. is 1.593 at 25°/4°; the mol. vol. is 125.6; the mol. vol. of the water is 13.6; and the mol. vol. of the ammonia, 18.1. E. Birk and W. Biltz obtained 1.595 at 0°/4° for the sp. gr. The heat of formation is 10.5 Cals. per mol. of ammonia. The vap. press. curves at different temp. are shown in Fig. 75, and:

	-11°	0°	10°	18°	26°
p . . .	14.5	32.3	65.5	110.5	175.5 mm.

By reducing the press., **cobaltous aquomonamminofluoride**, $\text{CoF}_2 \cdot \text{H}_2\text{O} \cdot \text{NH}_3$, is formed with a sp. gr. 2.471 at 25°/4°; mol. vol., 53.43; mol. vol. of the water, 13.6; and the mol. vol. of the ammonia, 18.1. The vap. press. at 34°, 46.5°, and 61.5° were, respectively, 13.8, 31.5, and 76.4 mm.—Fig. 75. The heat of formation is 12.5 Cals. per mol. of ammonia. There is also formed at 61.5°, **cobaltous aquohexamminofluoride**, $\text{CoF}_2 \cdot \text{H}_2\text{O} \cdot \frac{1}{2}\text{NH}_3$. N. Costachescu observed that if cobalt tetrahydrate is dissolved in warm pyridine, and the filtered soln. allowed to crystallize, brick-red, acicular crystals of **cobaltous diaquotetrapyridine fluoride**, $[\text{Co}(\text{H}_2\text{O})_2\text{Py}_4]\text{F}_2 \cdot \text{H}_2\text{O}$, are formed. The salt loses pyridine on exposure to air, absorbs some moisture from the atmosphere, and leaves behind tetrahydrated cobalt fluoride. The same salt remains when the soln. of the complex salt in water or alcohol is evaporated. O. Hassel and co-workers found that the compound formed with boron trifluoride, namely, **cobaltous hexamminofluoborate**, $[\text{Co}(\text{NH}_3)_6](\text{BF}_4)_2$, has a space lattice with $a=11.31 \text{ \AA}$; and G. B. Naess and O. Hassel, **cobaltous hexamminofluosulphonate**, $[\text{Co}(\text{NH}_3)_6](\text{SO}_3\text{F})_2$.

FIG. 75.—The Dissociation Pressures of the Cobalt Aminofluorides.

C. Poulenc observed that cobaltous fluoride is slowly attacked by conc. nitric acid in the cold, but more quickly when heated. Red phosphorus has no perceptible action; and similarly with arsenic and with carbon. C. Poulenc found that the salt is insoluble in benzene, alcohol, and ether. According to O. Ruff and E. Ascher, 12 per cent. acetic acid attacks the salt slowly in the cold, but when heated the salt dissolves freely. N. Costachescu said that cobaltous fluoride is insoluble in pyridine. Crystalline silicon reacts with the fluoride when heated below redness; sodium, magnesium, aluminium, and zinc react vigorously when heated with the fluoride, but no reaction was observed with iron or with copper. When heated with 33 per cent. soda-lye, a blue soln. containing cobalt is formed. C. Poulenc obtained cobaltous oxide and sodium fluoride by melting cobaltous fluoride with sodium carbonate.

Complex salts of cobaltous fluoride.—C. Poulenc prepared **ammonium cobalt tetrafluoride**, $(\text{NH}_4)_2\text{CoF}_4$, by fusing cobaltous chloride with an excess of ammonium fluoride, and treating the slowly-cooled mass with boiling alcohol. A. Kurtenacker and co-workers studied the equilibrium conditions in the system: $\text{CoF}_2 \cdot \text{NH}_4\text{F} \cdot \text{H}_2\text{O}$ at 20°, and found the solubility curve, S grms. per 100 grms. of soln., to be:

NH_4F	2.9	9.7	12.4	18.4	20.8	24.1	34.3
$S(\text{CoF}_2)$	0.34	0.21	0.08	0.02	0.015	0.010	0.009
Solid phase	$\text{CoF}_2 \cdot 4\text{H}_2\text{O}$		$2\text{NH}_4\text{F} \cdot \text{CoF}_2 \cdot 2\text{H}_2\text{O}$				

corresponding with the formation of $(\text{NH}_4)_2\text{CoF}_4 \cdot 2\text{H}_2\text{O}$. Analogous results were obtained at 50° . C. Poulenc observed that the violet crystalline powder is freely soluble in water, and acids, but insoluble in alcohol. It decomposes at a red-heat, giving off ammonium fluoride, and leaving cobalt fluoride behind. The *dihydrate*, $(\text{NH}_4)_2\text{CoF}_4 \cdot 2\text{H}_2\text{O}$, was obtained by H. von Helmolt, by boiling freshly-precipitated cobaltous hydroxide with a neutral soln. of ammonium fluoride; R. Wagner, from a mixed soln. of the component salts; and, as indicated above, by E. Böhm, from a soln. of cobaltous hydroxide in 43 per cent. hydrofluoric acid, saturated with ammonia. J. J. Berzelius said that the salt furnishes a pale red, crystalline mass, slightly soluble in water. E. Böhm said that the pale red crystals are microscopic cubes, and H. von Helmolt, 4-sided tetragonal plates, sparingly soluble in water. E. Böhm found the salt is soluble in dil. acids, and with conc. hydrochloric acid forms cobaltous chloride. C. Poulenc also prepared **potassium cobalt tetrafluoride**, K_2CoF_4 , by heating cobalt chloride with potassium hydrofluoride for some hours at 220° , and then at the m.p. The slowly-cooled mass is to be washed with boiling 97 per cent. of alcohol. The garnet-red, quadratic plates have a sp. gr. 3.22; they are sparingly soluble in water, almost insoluble in alcohol, ether, and benzene; freely soluble in hydrofluoric, hydrochloric, and nitric acids; decomposed when heated with sulphuric acid, or with alkali-lye, or alkali carbonate. Ammonia gradually colours the crystals red. The salt is decomposed by heat, with the formation of cobaltic oxide, and the volatilization of potassium fluoride. The salt dissolves in molten alkali silicates, to form a blue glass. J. J. Berzelius prepared a rose-red hydrate from a soln. of the component salts; and, according to R. Wagner, the product is **potassium cobalt trifluoride**, $\text{KF} \cdot \text{CoF}_2 \cdot \text{H}_2\text{O}$. A. Kurtenacker and co-workers studied the equilibrium conditions in the system: $\text{CoF}_2\text{--KF--H}_2\text{O}$ at 20° , and found the solubility curve, S grms. per 100 grms. of soln., to be:

KF	1.2	1.6	2.3	13.8	20.8
S(CoF_2)	0.86	0.18	0.11	0.13	0.005

corresponding with the existence of KCoF_3 , and similarly at 50° . R. Wagner also prepared crystals of **sodium cobalt trifluoride**, $\text{NaF} \cdot \text{CoF}_2 \cdot \text{H}_2\text{O}$, from a mixed soln. of the component salts. The composition of this complex fluoride is not well established. A. Kurtenacker and co-workers found that after 2 months' shaking of the system $\text{CoF}_2\text{--NaF--H}_2\text{O}$ at 20° and at 50° , only an incomplete formation of $\text{CoF} \cdot \text{NaF}$ takes place.

N. N. Ray prepared **cobalt fluoberyllate**, $\text{CoBeF}_4 \cdot 7\text{H}_2\text{O}$, by the action of cobalt nitrite on the theoretical quantity of ammonium fluoberyllate. The pale violet crystals of the *heptahydrate* have a sp. gr. 1.867 at $30^\circ/4^\circ$, and a mol. vol. 144.6. It loses a mol. of water in air at 30° to 35° , 4 mols. in vacuo over sulphuric acid, and 5 mols. at 100° . R. F. Weinland and O. Köppen evaporated a soln. of aluminium hydroxide and of cobalt hydroxide or carbonate in hydrofluoric acid, at ordinary temp., over lime, and obtained reddish-white crystals of **aluminium cobalt pentafluoride**, $\text{AlF}_3 \cdot \text{CoF}_2 \cdot 7\text{H}_2\text{O}$, sparingly soluble in dil. and conc. hydrofluoric acid. E. Rimbach and H. F. C. Kilian obtained **ceric cobalt decafluoride**, $2\text{CeF}_4 \cdot \text{CoF}_2 \cdot 7\text{H}_2\text{O}$, in pale pink crystals from a mixed soln. of ceric and cobalt hydroxides in hydrofluoric acid. B. Gossner, and P. Engelskirchen prepared **cobaltous fluotitanate**, $\text{CoTiF}_6 \cdot 6\text{H}_2\text{O}$; H. Töpsöe, and B. Gossner, **cobaltous fluostanate**, $\text{CoSnF}_6 \cdot 6\text{H}_2\text{O}$; B. Santesson, and A. Streng, **cobaltous fluocolumbate**, $\text{Co}_5\text{H}_5\text{C}_3\text{F}_{30} \cdot 28\text{H}_2\text{O}$, which is insoluble in and decomposed by water. E. Petersen prepared **cobalt fluovanadate**, $\text{VF}_3 \cdot \text{CoF}_2 \cdot 7\text{H}_2\text{O}$, by allowing a mixed soln. of the component salts to evaporate slowly, or to stand for some time; and A. Piccini and G. Georgis obtained it by the prolonged electrolysis of a soln. of a vanadic oxide and cobalt carbonate in hydrofluoric acid. The crystals are dark green when moist, brownish-green when dry; they are probably monoclinic, and are stable at 100° , but lose water at 170° . A. Piccini and G. Georgis prepared **cobalt fluoxyvanadate**, $\text{VOF}_2 \cdot \text{CoF}_2 \cdot 7\text{H}_2\text{O}$, by reducing electrolytically a soln. of

vanadic acid and a little less than the required mol. proportion of cobalt carbonate in hydrofluoric acid. When the soln. is intensely blue, it is filtered and evaporated. The bottle-green prisms have a violet reflex; and they begin to lose water at 80° , becoming anhydrous at 160° . E. Petersen prepared dark green crystals of **chromic cobalt pentafluoride**, $\text{CrF}_3 \cdot \text{CoF}_2 \cdot 7\text{H}_2\text{O}$, by allowing a mixed soln. of the component salts to stand for some time, or to evaporate very slowly. The dark green crystals are isomorphous with the corresponding vanadium salt. They are stable at 100° , but lose water at 200° . M. Delafontaine obtained crystals of **cobalt oxyfluomolybdate**, $\text{MoO}_2\text{F}_2 \cdot \text{CoF}_2 \cdot 6\text{H}_2\text{O}$, by evaporating a soln. of eq. proportions of cobalt hydroxide or carbonate, and molybdic oxide in hydrofluoric acid. According to B. Gossner, the dark green, hexagonal crystals are isomorphous with the corresponding fluosilicate—**6.** 40, 56; they are stable in dry air, but they decompose when heated. O. T. Christensen prepared **manganic cobaltous pentafluoride**, $\text{MnF}_3 \cdot \text{CoF}_2 \cdot 4\text{H}_2\text{O}$, soluble in water; and R. F. Weinland and O. Köppen prepared **ferric cobaltous pentafluoride**, $\text{FeCl}_3 \cdot \text{CoCl}_2 \cdot 7\text{H}_2\text{O}$, in rose-red crystals, by evaporating a mixed soln. of the component salts in dil. hydrofluoric acid over calcium chloride at ordinary temp.

Cobaltic fluoride.—O. Ruff, and O. Ruff and E. Ascher prepared the anhydrous trifluoride by the action of fluorine on cobalt dichloride in a quartz tube at 150° . F. Fichter and H. Wolfmann, and N. C. Jones found that some cobaltic fluoride, CoF_3 , is formed in aq. soln. when a soln. of cobaltous fluoride is treated with fluorine. According to G. A. Barbieri and F. Calzolari, when a sat. soln. of cobaltous fluoride, in 40 per cent. hydrofluoric acid, is electrolyzed in a platinum dish as anode, and a platinum wire as cathode, with anodic current density of 1 ampere per sq. dm., cobaltic fluoride, $\text{CoF}_3 \cdot n\text{H}_2\text{O}$, is deposited as a green powder which does not re-dissolve when the current is cut off. According to E. Birk, G. A. Barbieri and F. Calzolari, the salt is the *hemiheptahydrate*, $2\text{CoF}_3 \cdot 7\text{H}_2\text{O}$, and hence its formula may be: $\text{Fe}_2\text{F}_6 \cdot 7\text{H}_2\text{O}$, by analogy with $\text{Cr}_2\text{F}_6 \cdot 7\text{H}_2\text{O}$, $\text{Fe}_2\text{F}_6 \cdot 9\text{H}_2\text{O}$, and Al_2F_6 ; or it may be written $[\text{CoF}_3(\text{H}_2\text{O})_3]_2\text{H}_2\text{O}$, analogous with the corresponding hydrates of ferric, chromic, and aluminium fluorides. The X-radiogram shows that the hydrate belongs to the bimolecular type characteristic of $\text{Cr}_2\text{F}_6 \cdot 7\text{H}_2\text{O}$. O. Ruff and E. Ascher found that the anhydrous fluoride forms light brown, hygroscopic crystals belonging to the hexagonal system. The lattice dimensions are $a=7.64 \text{ \AA.}$, $c=3.66 \text{ \AA.}$; $a:c=1:0.508$; the vol. of the lattice is $185 \times 10^{-24} \text{ c.c.}$; and there are 4 mols. per unit cell. F. Ebert found that the X-radiograms of the crystals have the parameter, if rhombohedral, $a=3.664$, and $\alpha=87^{\circ} 20'$; and if hexagonal, $a=5.061 \text{ \AA.}$, and $c=6.63$, and $a:c=1:1.31$. The vol. of the elementary rhombohedral cell is $49.05 \times 10^{-24} \text{ c.c.}$ per mol. The shortest distance between the cobalt and fluorine atoms is 2.02 \AA. The calculated sp. gr. is 3.89—O. Ruff and E. Ascher obtained 4.14—and the observed value is 3.88. J. A. A. Ketelaar found that the crystals are hexagonal, and isomorphous with those of iron, aluminium, palladium, and rhodium. W. Nowacki studied the lattice structure. The sp. gr. is 3.88, and that calculated from the X-radiogram is 4.14. E. Birk found the sp. gr. of the hemiheptahydrate to be 2.314 at $25^{\circ}/4^{\circ}$; and the calculated mol. vol., 154.7 . According to O. Ruff and E. Ascher, when the trifluoride is heated in an inert gas, it forms cobaltous fluoride at 350° . K. Jellinek and R. Koop found for the partial press. of the fluorine in cobaltic fluoride, 3.8×10^{-65} at 197° ; 3.5×10^{-57} at 254° ; and 1.3×10^{-49} at 322° . The heat of formation of the anhydrous fluoride is about 240 Cals. K. Jellinek and R. Koop gave for $(2\text{CoF}_2, \text{F}_2)=159.2 \text{ Cals.}$; for $(\text{Co}, \text{F}_2)=160.7 \text{ Cals.}$; and for $(\text{Co}, 1\frac{1}{2}\text{F}_2)=240.3 \text{ Cals.}$ P. Henkel and W. Klemm studied the magnetic properties.

According to O. Ruff and E. Ascher, cobaltic fluoride in hydrogen at 200° and 250° is reduced to cobaltous fluoride, and the reduction is complete at a red-heat. K. Jellinek and R. Koop found for the equilibrium constant $K=P_{\text{HF}}^2/P_{\text{H}_2}$, of the reaction: $2\text{CoF}_3 + \text{H}_2 \rightleftharpoons 2\text{CoF}_2 + 2\text{HF}$, $K=0.0001622$ at 197° ; 0.00490 at 254° ; and 0.1698 at 322° ; or, $P_{\text{HF}}=1.27, 6.81, \text{ and } 33.75$, respectively. According

to O. Ruff and E. Ascher, when cobaltic fluoride is heated in air, it becomes rose-coloured at 250° to 300° , forming cobaltous fluoride or a basic salt, and it is converted into the black oxide at 450° to 500° . G. A. Barbieri and F. Calzolari said that the hydrated salt remains unchanged for several days in a desiccator, but in air it gradually becomes grey and then red in colour. When the anhydrous salt is treated with water, O. Ruff and E. Ascher found that oxygen is evolved, with the formation of a red soln. and black precipitate; water vapour rapidly darkens the colour of the salt at ordinary temp. G. A. Barbieri and F. Calzolari observed that the addition of a few drops of water to the hydrate blackens the salt, owing to the formation of cobaltic hydroxide; hydrogen dioxide reduces the sulphuric acid soln. of the hydrate immediately.

O. Ruff and E. Ascher found that bromine vapour above 100° reacts with the anhydrous salt, forming a bromiferous intermediate product, and cobaltous fluoride as end-product; when heated with iodine, there is a vigorous reaction, and cobaltous fluoride being formed. When the trifluoride is heated in hydrogen chloride, cobaltous chloride is formed. Forty per cent. hydrofluoric acid acts on the anhydrous salt, oxygen is evolved, and the red soln. becomes green, a residue—possibly the hydrated salt—remains. With conc. hydrochloric acid, chlorine is evolved, and a soln. of cobaltous chloride is formed.

According to J. Fischer and W. Jaenckner, there is a detonation when a mixture of sulphur and the anhydrous trifluoride is warmed, sulphur tetrafluoride and cobaltous fluoride is formed. O. Ruff and E. Ascher observed that with hydrogen sulphide at ordinary temp., cobaltous fluoride is formed, with evolution of heat, and cobalt sulphide is produced when the mixture is heated. When the trifluoride is heated to 200° in contact with sulphur dioxide, cobaltous fluoride is formed. When the trifluoride is heated with conc. sulphuric acid, oxygen and hydrogen fluoride are given off, and cobaltous sulphate remains in soln. G. A. Barbieri and F. Calzolari observed that the hydrate forms a brown soln. with sulphuric acid, which, when diluted, turns green.

O. Ruff and E. Ascher found that when heated below 100° in ammonia, the mixture reacts violently, forming cobaltous fluoride and a white sublimate of ammonium fluoride. E. Birk observed that the hydrated trifluoride takes up ammonia at 70° to 80° , with the loss of water, and the formation of luteo- and purpureo-fluorides. G. A. Barbieri and F. Calzolari found that the sulphuric acid soln. of the hydrated salt turns red when gently heated, or when treated with a reducing agent like a nitrite, hydroxylamine, hydrazine, or hydrogen dioxide. O. Ruff and E. Ascher observed that conc. nitric acid in the cold forms a dark green soln. which, when heated, gives off oxygen and forms a red soln. of cobaltous nitrate. Red phosphorus reacts when warmed with the anhydrous fluoride, and cobaltous fluoride is produced; similarly with arsenic.

O. Ruff and E. Ascher found that carbon also reacts when warmed with the trifluoride, forming cobaltous fluoride. The anhydrous fluoride is insoluble in benzene, alcohol, and ether. When alcohol is added to the brown sulphuric acid soln. of the hydrate, G. A. Barbieri and F. Calzolari observed that its colour changes to red. O. Ruff and E. Ascher found that 12 per cent. acetic acid in the cold forms a brown soln. which, when warmed, gives off oxygen with the separation of a black precipitate. The trifluoride reacts vigorously when it is heated with crystalline silicon, and cobaltous fluoride is formed.

According to O. Ruff and E. Ascher, the trifluoride reacts vigorously when heated with sodium, magnesium, aluminium, zinc, copper, iron, and cobalt—in the latter case, $2\text{CoF}_3 + \text{Co} = 3\text{CoF}_2$. A 40 per cent. soln. of sodium hydroxide reacts with the trifluoride, giving off oxygen in the cold, and depositing a black precipitate. When the trifluoride is melted with sodium carbonate, cobaltous oxide and sodium fluoride are produced.

E. Böhm prepared the normal **cobaltic hexamminofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_3$, along with the fluochloride, by treating the hexamminochloride with hydrofluoric

acid. The yellow, prismatic crystals are sparingly soluble in cold water, and almost insoluble in acids. H. Drawe gave 2.072 for the sp. gr., and 80.65 for the mol. vol. A. Miolati and G. Rossi obtained **cobaltic hexamminohydrofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_6\text{H}_3$, or $[\text{Co}(\text{NH}_3)_6]\text{F}_3 \cdot 3\text{HF}$, by treating cobaltic hexamminocarbonate with an excess of hydrofluoric acid, and silver fluoride. The orange-yellow crystals lose 3 mols. of hydrogen fluoride at 105° . The salt is freely soluble in water, and the eq. conductivity, λ soln. of an eq. of the salt, $\frac{1}{3}[\text{Co}(\text{NH}_3)_6]\text{F}_6\text{H}_3$, in v litres of water at 25° , is:

v	.	.	32	64	128	256	512	1024
λ	.	.	110.4	123.4	142.0	167.3	205.1	263.6

W. Biltz, E. Birk, and E. Birk and W. Biltz prepared **cobaltic hexamminohydrofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_3 \cdot 6\text{HF}$, by precipitation from an aq. soln. of the neutral fluoride and 50 per cent. hydrofluoric acid, and subsequent crystallization from 0.1 per cent. hydrofluoric acid. The sp. gr. of the crystals is 1.938 at $25^\circ/4^\circ$, and the mol. vol. is 174.5. A litre of hot 0.1 per cent. hydrofluoric acid dissolves about 1.5 grms. of the salt. H. Seibt obtained yellow **cobaltic trisethylenediaminofluoride**, $[\text{Co en}_3]\text{F}_3$, by treating a soln. of the bromide with silver fluoride. J. Angerstein studied the absorption spectra of the soln.

A. Hiendlmayr, W. Biltz, and E. Birk and W. Biltz prepared **cobaltic aquopentamminofluoride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{F}_3$, by neutralizing the aq. soln. of the hydroxide with 40 per cent. hydrofluoric acid, cooled by ice. The wine-red crystals are very soluble in water; their sp. gr. is 1.748 at $25^\circ/4^\circ$, and the mol. vol. is 125.4. If an excess of hydrofluoric acid is employed, **cobaltic aquopentamminotrifluorohexahydrofluoride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{F}_3 \cdot 6\text{HF}$, is formed. The sp. gr. is 1.976 at $25^\circ/4^\circ$, and the mol. vol. 171.7. C. S. Borzekowsky prepared the dextro- and levo-forms of **cobaltic hydroxylaminebisethylenediamineamminohydroxide**, $[\text{Co}(\text{NH}_3)(\text{NH}_2\text{OH en}_2)(\text{OH})_3]$.

A. Hiendlmayr, and E. Birk prepared **cobaltic fluopentamminofluoride**, $[\text{Co}(\text{NH}_3)_5\text{F}]\text{F}_2$, by the action of ammonia on hemiheptahydrated cobaltous fluoride at 70° to 80° ; and a part of the salt—possibly hexamminofluoride—dissolves in ice-water, forming a yellow liquid, the remainder—the fluopentamminofluoride—forms a red soln. with warm water acidified with hydrofluoric acid.

H. Seibt prepared **cobaltic cis-fluobisethylenediamineamminofluoride**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{F}]\text{F}_2$, as a red, crystalline powder by shaking an aq. soln. of cobaltic cis-aquobisethylenediamineamminobromide, with an excess of freshly-precipitated silver oxide, adding 40 per cent. hydrofluoric acid, and evaporating to dryness. M. L. Ernsberger and W. R. Brode studied the absorption spectrum. H. Seibt obtained the corresponding **cobaltic trans-aquobisethylenediamineamminofluoride** by similarly treating trans-aquobisethylenediamineamminobromide. H. Seibt prepared **cobaltic trans-difluorobisethylenediaminefluoride**, $[\text{Co en}_2\text{F}_2]\text{F}$, in dark green crystals, by the action of hydrofluoric acid on carbonatobisethylenediaminehydroxide.

A. Miolati and G. Rossi also prepared a series of complex salts, thus: a soln. of boric acid in an excess of hydrofluoric acid converts cobaltic hexamminocarbonate into **cobaltic boron hexamminofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_3 \cdot 3\text{BF}_3 \cdot \text{HF}$, which appears as a yellow, crystalline powder. By replacing the boric acid with fluosilicic acid, **cobaltic silicon hexamminofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_3 \cdot 2\text{SiF}_4$, is formed as a yellow, crystalline powder; with titanilic acid, **cobaltic titanium hexamminofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_3 \cdot \text{TiF}_4 \cdot 2\text{HF}$, is formed as a yellow, crystalline powder; with ammonium metavanadate, **cobaltic vanadyl hexamminofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_3 \cdot 5\text{VO}_2\text{F}_2 \cdot 7\text{HF}$; with molybdenum dioxidefluoride, **cobaltic molybdenyl hexamminofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_3 \cdot 2\text{MoO}_2\text{F}_2$, as a yellow, crystalline powder; with tungsten dioxidefluoride, **cobaltic tungstyl hexamminofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_3 \cdot 2\text{WO}_2\text{F}_2$, as a yellow, crystalline powder; and with ammonium uranyl fluoride, **cobaltic uranyl hexamminofluoride**, $[\text{Co}(\text{NH}_3)_6]\text{F}_3 \cdot \text{UO}_2\text{F}_2$, as a yellow powder.

§ 15. Cobaltous Chloride

H. Davy¹ obtained cobaltous chloride, CoCl_2 , by heating finely-divided cobalt in a current of chlorine, and H. Rose observed that finely-divided cobalt takes fire in a current of chlorine, producing blue, crystalline scales of the anhydrous chloride. When the chloride is strongly heated in a retort, or in a current of chlorine, cobalt chloride sublimes to form crystalline spangles which are slippery to the touch. G. C. Winkelblech obtained the chloride in this manner. According to R. Weber, cobalt oxide is not attacked by chlorine so readily as is the case with nickel oxide;

and R. Wasmuth observed that at 500° , about half the oxide is converted into chloride. A. Michael and A. Murphy obtained the chloride by the action of carbon tetrachloride on cobalt oxide in a sealed tube at 100° . H. Quantin also used carbon tetrachloride vapour, or a mixture of carbon dioxide and chlorine at a red-heat. A. Camboulives found that the reaction with carbon tetrachloride begins at 550° . F. Bourion obtained the chloride by heating the oxide in the vapour of sulphur monochloride. The reaction begins at about 250° , and the temp. was gradually raised to 500° during 3 hrs., and the product cooled in hydrogen chloride. The product is not pure. A. Hantzsch heated cobalt hydroxide in the vapour of acetyl or benzoyl chloride and obtained a quantitative yield of cobalt chloride. G. N. Wyrouboff obtained the anhydrous salt by dehydrating the hydrate at 135° to 140° ; J. Bersch, and W. Biltz and B. Fetkenheuer recommended a temp. exceeding 140° ; and G. L. Clark and co-workers, 160° to 170° . A. L. Potilitzin found that the salt dried at 110° to 120° for 13 hrs. is not completely soluble in water, and to avoid the formation of insoluble basic salt, he recommended drying the hydrate first over sulphuric acid, then heating it at 100° , and finally gently warming the product in a current of hydrogen chloride mixed with chlorine. G. P. Baxter and co-workers obtained the chloride of a high degree of purity by heating the hydrate in quartz vessels in a current of hydrogen chloride. F. W. O. de Coninck obtained the anhydrous salt by heating one of the hydrates with glycol under pressure. W. G. Leison, F. Rose, H. Copaux, and W. Biltz prepared the salt by heating cobaltic chloropentamminochloride. G. P. Baxter and F. B. Coffin, and T. W. Richards and G. P. Baxter observed that the product is of a high degree of purity if the ammine be heated in a quartz vessel, and the ammonium chloride be expelled by heating the product in a current of nitrogen and hydrogen chloride.

According to R. Engel, the *monohydrate*, $\text{CoCl}_2 \cdot \text{H}_2\text{O}$, is formed when a soln. of the hexahydrate is evaporated to dryness at 100° . A. Ditte obtained it by passing hydrogen chloride through a soln. of the hexahydrate in hydrochloric acid at 35° ; and G. N. Wyrouboff obtained it by warming the hexahydrate at 80° to 90° . A. Hantzsch and F. Schlegel said 90° , and A. L. Potilitzin, 100° . A. L. Potilitzin observed that when the dihydrate is heated to 100° , dark violet spots appear on the rose-red hydrate in about 1 hour, they do not disappear on cooling, and they increase in size when the hydrate is kept at 100° ; until, in $4\frac{1}{2}$ hrs., all is converted into violet monohydrate. The product obtained by dehydrating the higher hydrates is said to be amorphous, and A. L. Potilitzin found that needle-like crystals can be produced by heating a higher hydrate dissolved in absolute alcohol at 90° to 95° , on an air-bath, until all the alcohol is removed. A. Ditte said that a *hemitrihydrate*, $\text{CoCl}_2 \cdot 1\frac{1}{2}\text{H}_2\text{O}$, is produced when hydrogen chloride is passed slowly through a soln. of cobalt chloride saturated at 12° ; but A. Hantzsch could not confirm the existence of these salts by observations on the dehydration of the higher hydrate. The *dihydrate*, $\text{CoCl}_2 \cdot 2\text{H}_2\text{O}$, was prepared by J. Bersch, and E. J. Mills by heating a higher hydrate; by drying the higher hydrate in a desiccator over sulphuric acid; or, according to P. Sabatier, by drying the higher hydrate in vacuo—A. L. Potilitzin added that 4 or 5 days are needed for the operation, but H. Lescœur found that about 24 hrs. are needed if the salt be kept over conc. sulphuric acid at 30° to 40° ; and A. L. Potilitzin found that only 4 hrs. are necessary at 45° to 52° . A. Neuhaus, and G. L. Clark and co-workers recommended keeping the hexahydrate over conc. sulphuric acid for 36 hrs. at 50° . According to A. Etard, the dihydrate is the solid phase in sat. aq. soln. at temp. exceeding 50° . A. Hantzsch reported a blue, unstable form of the dihydrate analogous with a blue, unstable cobaltous bispyridinochloride, $\text{CoCl}_2 \cdot 2\text{C}_6\text{H}_5\text{N}$. J. Bersch reported the *tetrahydrate*, $\text{CoCl}_2 \cdot 4\text{H}_2\text{O}$, to be formed by heating the hexahydrate at 116° . It was also mentioned by A. Neuhaus, and F. W. O. de Coninck; and H. Benrath found that the monoclinic crystals are stable between 46° and 48° approximately. A. Hantzsch's works on the dehydration, and H. Lescœur's observations on the vapour press. of the hydrates of cobalt chloride gave no evidence of the *existence*

of the tetrahydrate. I. H. Derby and V. Yngve, and G. L. Clark and co-workers also failed to prepare the tetrahydrate. W. Stortenbeker observed that the tetrahydrate forms solid soln. with the tetrahydrate of manganous chloride, and that there are two forms, α -tetrahydrate and β -tetrahydrate. A. Benrath's observations on the solubility of cobaltous chloride are summarized in Fig. 76. The diagram shows the equilibrium conditions of the three hydrates.

The aq. soln. is obtained by dissolving one of the hydrates in water. According to J. L. Proust, C. F. Bucholz, and L. R. von Fellenberg, when the sublimed, blue chloride is exposed to air, it acquires a red colour, and it then readily dissolves in water, but if the salt has not been previously exposed to air, it requires 12 hrs. or more to get it into soln. The aq. soln. of cobalt chloride is readily formed by dissolving the oxide, hydroxide or carbonate in hydrochloric acid, or by dissolving the metal in hydrochloric acid, or in aqua regia.

If the aq. soln. be evaporated for crystallization, the *hexahydrate*, $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$, is formed. The salt was prepared by H. Copaux, R. Engel, L. R. von Fellenberg, F. Feigl and co-workers, H. J. Kapulitzas, and A. L. Potilitzin. E. J. Mills obtained the aq. soln. by repeatedly digesting cobaltic chloropentamminodichloride with hydrochloric acid. The *octohydrate*, $\text{CoCl}_2 \cdot 8\text{H}_2\text{O}$, mentioned by C. F. Rammelsberg, and H. J. Brooke, could not be prepared by J. C. G. de Marignac, and no one else has recognized its existence. The product is the hexahydrate.

Physical properties of cobalt chloride.—According to J. L. Proust, the colour of the sublimed chloride is flax-flower blue, according to C. F. Bucholz, blue; and according to L. R. von Fellenberg, bluish-green. R. Engel said that the crystals of the anhydrous salt are pale blue, and that also is the colour of the loosely-coherent mass obtained by dehydration. F. G. Donnan and H. Bassett observed that the colour of the anhydrous salt is pale blue at ordinary temp., and reddish-violet at the b.p. of liquid air. The monohydrate was also stated by R. Engel, A. Ditte, and A. L. Potilitzin, etc., to be violet or bluish-violet; the hemitrihydrate, according to A. Ditte, is also bluish-violet; the dihydrate, according to J. Bersch, is deep violet-blue; if not completely dehydrated, the colour is rose-red tinged with violet. J. Bersch, and A. Neuhaus said that the tetrahydrate is peach-red, or red; W. Stortenbeker studied the solid soln. of cobalt and manganous chlorides, and from the results inferred the existence of isomeric forms, α -tetrahydrate and β -tetrahydrate, and the colours deduced from their solid soln. are, respectively, violet, and violet-red. According to A. Neuhaus, and O. Mügge, the carmine-red, or red crystals of the hexahydrate are pleochroic, having α , ultramarine to prussian-blue; β , a pale carmine-red; and γ , a clear carmine-red.

Observations on the changes in the colour of soln. of cobaltous chloride were made by J. Hellot, P. J. Macquer, and J. L. Proust. According to J. Bersch, and A. Vogel, the carmine-red or pink aq. soln. of cobalt chloride turn violet-blue when heated, and this is the case even with very dilute soln. The changes in colour of the red soln. on heating correspond with the changes in colour in passing from the hexahydrate to the anhydrous chloride, and, roughly, with the zones of stability of the different hydrates on the solubility curves. The aq. soln. also turns blue when mixed with alcohol, or with conc. hydrochloric or sulphuric acid, and this the more readily, the lower the temp. The red colour can be restored by diluting the soln. with water, and in some cases by cooling the blue liquid. The more dilute soln., if it contains free acid, also turns blue when it is concentrated by heat, or by standing over sulphuric acid under reduced pressure. The blue soln. in alcohol on dilution with water, becomes first violet and then red, and it also becomes red when cooled much below 0° . According to R. Engel, and J. Kallir, the red, aq.

Fig. 76.—The Solubility of the Cobaltous Chloride.

soln. also turns blue when it is treated with the chlorides of zinc, tin (ous), mercury (ic), and lithium. F. W. O. de Coninck also found that the red soln. becomes violet in sunlight. For the application of the facts to the preparation of an invisible or sympathetic ink, *vide supra*, uses of cobalt.

One of the earliest guesses made to explain these colour-changes was to assume that the red colour is due to the existence of the hexahydrate in soln., and that the blue colour is due to the formation of a lower hydrate. The *hydration hypothesis* was discussed by C. H. L. von Babo, A. Benrath, M. Berthelot, A. R. Brown, G. Chancel, G. Charpy, F. Clowes, A. Étard, J. H. Gladstone, R. Godeffroy, W. N. Hartley, N. S. Kurnakoff, B. E. Moore, A. L. Potilitzin, W. J. Russell, W. J. Russell and W. J. Orsman, H. Schiff, C. R. C. Tichborne, M. S. Wrewsky, and G. N. Wyruboff. The hypothesis, though plausible, does not explain all the phenomena, as, for example, the different effects produced by anhydrous calcium and zinc chlorides. Accordingly, R. Engel elaborated the *molecular compound hypothesis*; he assumed that the various colours are produced by the presence of double salts in soln. He supposed that when the aq. soln. is heated, the salt is partially hydrolyzed, the liberated hydrochloric acid then unites with the unchanged cobalt chloride to form a blue chlorohydrate—*vide infra*. The change from blue to red on adding zinc or mercuric chloride, is attributed to the formation of chlorohydrates by these salts in preference to the chlorohydrate of the cobalt salt, whereas the blue coloration produced by calcium, and lithium chlorides, is due to the formation of double salts—*e.g.*, A. Chassevant's $\text{CoCl}_2 \cdot \text{LiCl} \cdot 3\text{H}_2\text{O}$. The subject was discussed by H. le Chatelier, G. N. Wyruboff, and J. Kallir. W. Hardt, as a result of his study of the spectra and electrical conductivities of alcoholic soln., concluded that electrically neutral molecules of cobalt chloride are not present, but rather does the salt form with alcohol *Molekülkomplexen*. The hypothesis fits in with some of the facts, but it has to be supported by too many unproved subsidiary hypotheses to be satisfactory.

J. Bersch postulated an *isomeric hypothesis*, for he said that there is a change from red hexahydrate to blue hexahydrate between 30° and 35° , and he thus attributed the different colours to the presence of different isomers. Neither A. L. Potilitzin, nor H. Lesceur could confirm this conclusion, and they showed that J. Bersch was probably misled by the hexahydrate, at its transition point, melting in its water of crystallization and producing a small proportion of a blue, saturated soln. I. Rohde and E. Vogt found that the absorption spectra of soln. of cobaltous chloride in pyridine, shifts from the red to the blue between about 10° to 50° . The absorption spectrum is not due to a continuous change in the absorption curve for one molecular species, but is due to the displacement of equilibrium between two kinds of molecules as the temp. changes. There is a unimolecular reaction, $\text{Co}_{\text{red}} \rightleftharpoons \text{Co}_{\text{blue}}$, which has a thermal value of 11.7 Cals. In a soln. which is blue at 50° , there is present 90 per cent. of Co_{red} , and at 90° , the Co_{red} amounts to 50 per cent. A. Hantzsch and co-workers, and F. Schlegel postulated the existence of red and blue, what he called pseudo-salts, *e.g.*, $[\text{Co}(\text{H}_2\text{O})_n]\text{Cl}_2$, and blue true-salts, *e.g.*, $\text{CoCl}_2 \cdot n\text{H}_2\text{O}$, and suggested that the solid, purple dihydrate gives a blue form in soln. which is unstable in the solid state. He assumed that hydration is the primary cause of the variations of colour. The compound $\text{CoCl}_2(\text{H}_2\text{O})_4$ is red; $[\text{Co}(\text{H}_2\text{O})_6]\text{Cl}_2$ is rose-red; and the solid $\text{CoCl}_2(\text{H}_2\text{O})_2$ is blue or violet, since it is supposed to exist in *cis* or *trans* modifications:

W. Ostwald suggested an explanation based on the *ionic hypothesis*. He said:

The colours of salt soln. are essentially the colours of the parts of molecules or ions contained therein, and all salt soln. which contain a certain ion, must exhibit the characteristic colour of that ion. Should the expected colour not appear, we may conclude that the corresponding ion is absent. The red colour of dil. soln. of cobalt salts, for instance,

indicates the presence of cobalt ions. The sulphate, nitrate, chloride, etc., have the same colour in soln., and the colour is independent of the nature of the negative ion. If one of these soln. be boiled with an excess of potassium cyanide, it is decolorized, and the colourless soln. no longer shows the reactions of cobalt. The compound potassium cobaltcyanide, K_3CoCy_6 , has been formed, and free cobalt ions are no longer present. The green colour of a soln. of a nickel salt is changed under the same conditions, to yellow, which shows that the nickel ions have entered into combination. If the foregoing statement is correct, the intensity of the coloration of those salts whose ions are coloured must be proportional to the quantity of those ions, supposing that the part of the salt which is not separated into ions is itself colourless. . . . Special relations are observed when the non-ionized salt is itself coloured. For instance, anhydrous cupric chloride, or a soln. of this salt in inert solvents, where it is not separated into ions, is coloured intensely yellow. Therefore a soln. of this salt, which contains many free ions of copper and chlorine, but also a certain amount of non-ionized molecules of cupric chloride, will show the colour which results from mixing the blue of the copper ions with the yellow of cupric chloride. Agreeably with this conclusion, it is found that very dil. soln. of cupric chloride—which contain but little non-ionized salt—are blue, like soln. of other cupric salts, but the more concentrated the soln. become and therefore the greater becomes the number of non-ionized molecules, the more does the colour incline to green. The addition of hydrochloric acid, or the raising of the temp., acts in the same way as increasing the concentration; in both cases, the number of copper ions decreases, and the number of undecomposed molecules of cupric chloride increases.

The hypothesis was favoured by W. C. D. Whetham. This hypothesis requires that the blue colour produced by a rise in temp. is attended by a marked decrease in ionization, and that the addition of other chlorides makes the soln. blue by decreasing the ionization of cobalt chloride. This is not in accord with the observations of R. Salvadori, for F. G. Donnan and H. Bassett showed that they indicate that cobalt chloride in aq. soln. is less ionized at 0° than at 100° . N. Tarugi and G. Bombardini's observations at the b.p., and F. G. Donnan and H. Bassett's observations at the f.p. The former conclude that complete non-ionized cobalt chloride can exist in red soln.

F. G. Donnan and H. Bassett extended the ionic hypothesis to include the formation of complex ions. The *complex-ion hypothesis* assumes that in addition to the simple Co^{++} -ions and Cl^- -ions, there are also complex anions, say $CoCl_3^-$ and $CoCl_4^{--}$, in equilibrium such that the simple process of ionization $CoCl_2 \rightleftharpoons Co^{++} + 2Cl^-$ is followed by $CoCl_2 + 2Cl^- \rightleftharpoons CoCl_4^{--}$, or by $CoCl_2 + Cl^- \rightleftharpoons CoCl_3^-$. The non-ionized salt in soln. is supposed to be blue, and the complex anion in soln. is also blue, whilst the colour due to the cobalt atom when outside the immediate sphere of the chlorine atoms, appears to be red. Thus, the colour produced by the free cobalt cations in aqueous soln. is red; whilst the red colour of the solid hexahydrate is doubtless due to the fact that the water molecules intervene between the cobalt and chlorine atoms. This is in accord with A. Werner's co-ordination theory. The colours exhibited by the double chlorides are attributed in the case of zinc chloride to the greater tendency of zinc to enter into negative complex groups, the zinc double chloride will have the constitution: $Co-(ZnCl_4)$, whilst the calcium double chloride will have the constitution: $Ca-(CoCl_4)$, since cobalt has a greater tendency to form negative complexes than calcium. In agreement with this, the former double salt is red, whilst the latter is blue. It is suggested that anhydrous, solid cobaltous chloride may not possess the simple formula $CoCl_2$, but may correspond to some polymeric complex form such as $Co-(CoCl_4)$, its colour being determined by the strong absorption in the red produced by the complex grouping, $CoCl_4$. It is, at all events, a curious fact that the pale blue, anhydrous chloride becomes reddish-violet at the temp. of boiling liquid air. As in the case of the soln. in alcohol and in conc. hydrochloric acid, this change of colour may be due to the breaking up of the complex grouping on lowering the temp. by an exothermic process. The work of H. G. Denham and co-workers, on transport numbers, of B. E. Moore, P. Job, J. Groh, and J. Groh and R. Schmidt, on absorption spectra, and of H. Bassett and H. H. Croucher, on the equilibria of the complex salt of cobalt chloride with hydrochloric acid, and mercuric, magnesium, and zinc chlorides, favours the complex ion hypothesis. A. Benrath's determination of the b.p. of aq. soln. indicates that

salts which form complexes with cobalt chloride favour the formation of red soln., and those which favour the blue colour do not form complexes.

P. Vaillant concluded from his observations on the absorption spectra of soln. of cobalt salts, that the cobalt ion possesses its own colour independently of the molecule, and the addition of a colourless electrolyte may modify the colour of a solution containing an electrolyte with a coloured ion, both by changing the ionization and by causing dehydration. These two actions are independent of each other, and the latter depends on the tendency of the added electrolyte to form hydrates. In organic solvents, the molecule is in a definite state of hydration, which is generally lower than that in which it exists in aq. soln. The organic solvent, like an added electrolyte, exerts a dehydrating action. It is assumed that the phenomena are best interpreted by the ionic hypothesis coupled with some form of the hydration theory, which, alone, does not adequately explain the observed facts. G. N. Lewis also concluded with F. G. Donnan and H. Bassett, that complex anions are formed in blue cobalt soln., but emphasized the need for the assumption that the change from blue to red is also attended by hydration. C. Mazzetti, and H. C. Jones and co-workers advocated the same hypothesis. This is a form of the *solvation theory*—1. 15, 11—where the cations are supposed to be loaded with water molecules. Water is produced or consumed in the formation of the complex ions: $\text{CoCl}_2(\text{H}_2\text{O})_n + \text{Cl}(\text{H}_2\text{O})_m \rightleftharpoons \text{CoCl}_3(\text{H}_2\text{O})_p + (n+m-p)\text{H}_2\text{O}$. The solvation hypothesis was also discussed by H. C. Jones and H. P. Bassett, and E. O. Hulbert and co-workers. A. Kotschubey found that in these soln., the degree of solvation or hydration of the ions, and of the non-ionized salt, increases with dilution, and decreases with a rise of temp. A. Kotschubey did not accept the evidence that complex ions are formed in soln. of cobalt chloride, although he assumed that in red soln. containing mercuric, zinc, cadmium, stannous, or antimony chlorides, there are present complex ions of the type $[\text{CoCl}_4(\text{ZnCl}_2)_2]''$, and $[\text{CoCl}_4(\text{HgCl}_2)_2]$, but that the evidence for the formation of complexes of CoCl_4'' by the action of hydrochloric acid, or of the chlorides of ammonium, potassium, magnesium, or aluminium, with cobalt chloride soln. is not definitely established. More recent work, however, has in general favoured the complex ion hypothesis. A. Kotschubey attributed the change in colour, not to the formation of CoCl_4' , but rather to the passage from the $\text{Co}(\text{H}_2\text{O})_6''$ -ion to the $\text{Co}(\text{H}_2\text{O})_4''$ -ion to $[\text{Co}(\text{H}_2\text{O})_2\text{Cl}_2]$.

R. Hill and O. R. Howell, and O. R. Howell suggested that the colour of cobalt compounds—red or blue—depends on the state of co-ordination of the cobalt atoms. If the atom is surrounded by six other groups or atoms, the colour is red; and if only four groups or atoms, the colour is blue—*e.g.*, in crystals of magnesium oxide, where each magnesium atom is surrounded by six oxygen atoms, if some of the magnesium are replaced by cobalt atoms, the colour is pink. This hypothesis does not agree with that of L. Pauling on the structure of the crystal lattice of the blue salt. In red, aq. soln., each cobalt atom is supposed, by R. Hill and O. R. Howell, to be surrounded by six water mols. H. Bassett and H. H. Croucher conclude that *red*, aq. soln. of cobalt chloride may contain one or more of the red cations, $\text{Co}(\text{H}_2\text{O})_6''$, $\text{Co}(\text{H}_2\text{O})_4''$, $\text{Co}_2(\text{H}_2\text{O})_{10}''''$, or $\text{Co}_2(\text{H}_2\text{O})_6''''$; and *blue*, aq. soln. of cobalt chloride may contain the blue anions, CoCl_4'' , or $[\text{Co}(\text{H}_2\text{O})\text{Cl}_3]'$. Other ions are also theoretically possible. The simple Co'' -ion is red, but is not likely to exist in aq. soln. When the chlorides of bivalent metals are dehydrated beyond the tetrahydrate, they generally become complex, and the complexity increases with increasing dehydration. Accordingly, dihydrated cobalt chloride is not simply $\text{CoCl}_2 \cdot 2\text{H}_2\text{O}$, but rather $(\text{CoCl}_2 \cdot 2\text{H}_2\text{O})_2$, which may be either $[\text{Co}(\text{H}_2\text{O})_4]''[\text{CoCl}_4]''$ or else $[\text{Co}(\text{H}_2\text{O})_3\text{Cl}][\text{CoCl}_3(\text{H}_2\text{O})]'$.

The colour of the ion does not appear to depend on its co-ordination, but only on its ionic state; nor do the number of charges carried by the ions appear to affect the colour appreciably. The manifestation of colour in compounds of metals like cobalt, is determined by the possibility of electron transference between different quantum levels. In the case of cobaltous compounds there are three electrons which may be considered to be

fairly mobile, but of these, two are on the outermost sheath and one on the next inner shell. If one or both of the two outer electrons have been lost (as in positive cobaltous ions with one or two positive charges), then the third electron can move freely between the inner and outer shells, but, the two outer positions being similar, it makes little difference to the colour whether one or both positions are empty. This state of affairs corresponds to that of the red, positive ions. The accumulation of electrons around the cobalt atom, as in $[\text{Co}(\text{H}_2\text{O})\text{Cl}_3]$ and CoCl_4 , tends to make one of the outer electrons move into an inner position, which is possible, since the third quantum group in the cobalt atom is not completely filled. The deep blue colour of the complex cobalt anions appears to arise in this way.

The behaviour of the non-ionic cobaltous compounds is rather more difficult to foresee. In a general way, since each valency electron of the metal is now replaced by a pair of shared electrons, the effect might be similar to that caused by the piling up of electrons in ions such as CoCl_4^{--} , and in many cobaltous compounds this actually seems to be the case. Anhydrous cobalt chloride, considered by us to be non-ionic, is pale blue, and we should expect the non-ionic $[\text{Co}(\text{H}_2\text{O})_2\text{Cl}_2]$ also to be pale blue. The two shared electrons of a co-ordination covalency, when the co-ordination is to a neutral atom or molecule, clearly do not have this effect—doubtless because they are too firmly held by the atom to which they properly belong. In the cobaltous compounds they seem to exert little effect of any kind on the colour. In general, however, some effect would be expected, for the electronic environment, in which any electron-shifts occur in the outer levels of the ion, must depend to some extent on the number and nature of the atoms co-ordinated with the ion.

If the electron-shift which gives rise to the colour is that of an unshared electron—passing from the third to the fourth quantum level, or *vice versa*—then the compound in question has a red colour. If, however, the electron which moves between the two levels is one which is shared between the cobalt and another atom, *i.e.* a covalency electron, then a blue colour arises. It seems likely, however, that it is only indirectly of importance whether the moving electron is shared or unshared. The important point, in all probability, is that when an unshared electron is concerned, it is a 3_z electron of the third quantum level which moves between the third and fourth quantum levels, whereas when a shared electron is concerned, it is a 1_z electron of the fourth quantum level which makes the same jump.

The anhydrous salt when sublimed furnishes blue, loosely-coherent, crystalline spangles which feel like mica. W. Biltz reported the crystals to be hexagonal plates optically uniaxial, and with a negative birefringence. A. Ferrari said that the X-radiograms indicate that the pseudo-cubic lattice of the crystals is rhombohedral of the magnesium chloride type, having $a=7.08$ Å., and $c=17.35$ Å., and $a:c=1:2.45$, with 16 molecules per unit lattice. P. Niggl and W. Nowacki, R. J. Macwalter and S. Barratt, H. Grime and J. A. Santos, and V. M. Goldschmidt and co-workers discussed the subject. L. Pauling gave $a=6.14$ Å., and added that each cobalt atom is probably surrounded by six chlorine atoms approximately at the corners of a regular octahedron, six edges of which are shared with other octahedra so as to form a layer. The cadmium chloride structure appears to be the stable one for substances of the type MX_2 , where M has the co-ordination number 6, and the anion has a small polarizability. H. Bassett and H. H. Croucher assumed that the chlorine atoms are not ionized but are attached to the cobalt atoms by covalencies, the existence of the crystals being maintained by the six-co-ordinated condition of the metal atom. Each layer of octahedra in the crystals of cobalt can be regarded as a single, very complex molecule. The structure assumed by L. Pauling could result from the knitting together of a series of

chains containing four-co-ordinated cobalt. A. L. Potilitzin said that the monohydrate furnishes violet-blue, needle-like crystals; A. Ditte, that the hemihydrate furnishes dark bluish-violet, needle-like crystals; and J. Bersch, that the dihydrate furnishes a deep violet, crystalline powder, and the tetrahydrate peach-red crystals. H. Bassett and H. H. Croucher obtained the dihydrate as slender, purple prisms with oblique ends. A. Neuhaus said that the pseudo-rectangular crystals are monoclinic or triclinic. The twinning of the crystals of the dihydrate was studied by O. Lehmann. The hexahydrate furnishes red crystals, which, according to H. J. Brooke, belong to the monoclinic system having the axial

ratios $a : b : c = 1.4788 : 1 : 0.9452$, and $\beta = 122^\circ 19'$. O. Mügge gave $a : b : c = 1.473 : 1 : 0.9445$, and $\beta = 57^\circ 46'$. The (001)-cleavage is perfect, and the (110)-cleavage imperfect. The crystals were also examined by P. Groth, and J. C. G. de Marignac. O. Lehmann studied the twinning of the crystals; and O. Mügge, the pleochroism. The formation of large crystals in the magnetic field was observed by G. Roasio, and D. Samuracas.

The **specific gravity** of the anhydrous salt was found by L. Playfair and J. P. Joule to be 2.937; by A. Neuhaus, about 3.00; by G. P. Baxter and F. B. Coffin, 3.348 at $25^\circ/4^\circ$; by G. L. Clark and co-workers, 3.356 at $25^\circ/4^\circ$; and W. Biltz and E. Birk, 3.367 at $25^\circ/4^\circ$. A. Ferrari calculated 3.43 from the X-radiogram data. C. H. D. Bödeker gave 1.84 at 13° for the sp. gr. of the hexahydrate; A. Neuhaus gave 2.42; B. Gossner, 1.917; P. A. Favre and C. A. Valson, 1.898 at 23.9° ; and G. L. Clark and co-workers, 1.924 at $25^\circ/4^\circ$. A. Neuhaus also gave 2.216 for the sp. gr. of the tetrahydrate, and 2.42 for the dihydrate. G. L. Clark and co-workers gave 2.479 at $25^\circ/4^\circ$ for the sp. gr. of the dihydrate. The sp. gr. of soln. of cobalt chloride were measured by B. Franz, G. T. Gerlach, R. Wagner, P. A. Favre and C. A. Valson, G. Quincke, W. Biltz, R. Engel, P. F. Gaeher, O. R. Howell, J. Trötsch, W. W. J. Nicol, A. E. Oxley, J. Wagner, J. Grailich, P. Sabatier, H. C. Jones and co-workers, A. Heydweiller, L. Brant, G. Dreyer, S. Lussana and G. Bozzola, P. Moretto, and R. Wernicke. The results indicate the sp. gr. of soln. with :

CoCl ₂	1	2	4	6	8	10 per cent.
Sp. gr. { $18^\circ/4^\circ$	1.0076	1.0168	1.0356	1.0549	1.0747	1.0949
{ $20^\circ/4^\circ$	1.0073	1.0165	1.0350	1.0538	1.0735	1.0940
{ $25^\circ/4^\circ$	1.0069	1.0150	1.0335	1.0525	—	—

B. Franz's values are :

CoCl ₂	1	5	10	12	20	25 per cent.
Sp. gr. at 17.5°	1.0099	1.0496	1.0997	1.1579	1.2245	1.3002

R. Wagner gave for the sp. gr. of N -, $\frac{1}{2}N$ -, $\frac{1}{4}N$ -, and $\frac{1}{8}N$ -CoCl₂, the respective values 1.0571, 1.0286, 1.0144, and 1.0058. P. A. Favre and C. A. Valson, and G. G. and I. N. Longinescu discussed the calculated and observed sp. gr. of soln. B. Cabrera and co-workers gave for the sp. gr. of soln. with 0.1065 grm. of CoCl₂ per gram of soln. at θ , $1.1018\{1 - 0.00025(\theta - 20)\}$; and for soln. with 0.3206 grm. of CoCl₂ per gram of soln., $1.3630\{1 - 0.0003(\theta - 20)\}$. C. Winkler said that the sat. soln. in alcohol of sp. gr. 0.792 has a sp. gr. of 1.0107, and contains 23.66 per cent. CoCl₂. P. Moretto, and S. Lussana and G. Bozzola discussed the temp. of **maximum density**; and G. Dreyer gave for soln. with 0.883, 1.828, and 1.859 per cent. CoCl₂, the lowering of the temp. of maximum density of water (3.96), respectively 1.09° , 2.36° , and P. A. Favre and C. A. Valson found that with N gram-equivalent of cobalt chloride per kgrm. of water, the sp. gr. of soln. at 23.9° ; the vol. obtained by dividing the total weight of water and salt by the sp. gr.; and the successive increments in vol. produced by adding another eq. of salt, were as follows :—

N gram-equivalents	1	2	3	4	5	6	9.
Sp. gr.	1.055	1.101	1.141	1.177	1.209	1.238	1.309
Total volume	1061	1124	1189	1254	1319	1384	1582
Increments in volume	61	63	65	65	65	65	66

R. Engel, O. R. Howell, and J. Kendall and K. P. Monroe measured the sp. gr. of soln. in hydrochloric acid; C. Winkler, in ethyl alcohol; and A. Naumann and E. Vogt, in acetone. G. L. Clark and co-workers gave 38.70 for the **molecular volume** of the anhydrous salt at 25° ; and W. Biltz and E. Birk, 38.58 at 25° . W. Biltz, E. Moles, I. I. Saslawsky, and U. Panichi studied the observed and calculated mol. vol. H. H. Stephenson calculated a 32 per cent. contraction, and G. L. Clark and H. K. Buckner, a 25.86 per cent. contraction. G. L. Clark and co-workers gave 123.69 for the mol. vol. of the hexahydrate; and G. L. Clark and

H. K. Buckner, 15.9 per cent. for the contraction in the reaction: $\text{CoCl}_2 + 6\text{H}_2\text{O} = \text{CoCl}_2 \cdot 6\text{H}_2\text{O}$. A. Balandin made observations on the subject; and E. N. Gapon studied the relation between the m.p. and sp. gr. of the hexahydrate. G. L. Clark and co-workers observed a 20.91 per cent. contraction in the reaction: $\text{CoCl}_2 + 2\text{H}_2\text{O} = \text{CoCl}_2 \cdot 2\text{H}_2\text{O}$. F. Ephraim, R. Reinicke, and W. Fischer studied the mol. vol. of the salt; and W. W. J. Nicol discussed the mol. vol. of the soln. P. Vinassa discussed the mol. number; and G. Tammann, the **inner pressure** of soln. The coeff. of **diffusion** of soln. in agar-agar with 4.72 mgrms. per c.c., were found by F. Voigtländer to be 0.443, 0.83, and 1.33 sq. cm. per day respectively, at 0°, 20°, and 40°. Observations were also made by E. Rona, J. H. Long, M. Torre, and J. Schuhmeister; the last-named gave for a soln. with 1.5 gram-equivalents per litre at 18°, 0.46 gm. per sq. cm. per day. E. Rona measured the rate of diffusion in hydrochloric acid soln. O. R. Howell found the **surface tension** of a soln. of 120 grms. of the hexahydrate per litre at 20° to be 74.36 dynes per cm. Z. H. Skraup and co-workers studied the capillary rise in filter-paper; M. Padoa and G. Tabellini, the drop weight of molar soln. at different temp.; and H. Auer, the effect of a magnetic field of 20,000 gauss on the surface tension. O. R. Howell measured the surface tension of soln. in hydrochloric acid; and P. P. and N. S. Kosakewitsch, in alcoholic soln. R. Wagner gave for the **viscosity** of N -, $\frac{1}{2}N$ -, $\frac{1}{4}N$ -, and $\frac{1}{8}N$ -soln. at 25°, respectively 1.2041, 1.0975, 1.0482, and 1.0078—water unity. Measurements were made by O. R. Howell, and M. R. Schmidt and H. C. Jones. C. Mazzetti gave for the coeff. of viscosity, η , of soln. with C gram-equivalent of cobalt chloride per litre:

C		0.251	0.752	1.504	2.006	7.631
μ	$\left\{ \begin{array}{l} 13^\circ \text{ to } 14^\circ \\ 34^\circ \text{ to } 35^\circ \\ 45^\circ \text{ to } 46^\circ \\ 59^\circ \text{ to } 60^\circ \end{array} \right.$	$\left\{ \begin{array}{l} . \\ . \\ . \\ . \end{array} \right.$	$\left\{ \begin{array}{l} . \\ . \\ . \\ . \end{array} \right.$	$\left\{ \begin{array}{l} . \\ . \\ . \\ . \end{array} \right.$	$\left\{ \begin{array}{l} . \\ . \\ . \\ . \end{array} \right.$	$\left\{ \begin{array}{l} . \\ . \\ . \\ . \end{array} \right.$
		0.01278	0.01346	0.01515	0.01648	0.05983
		0.00821	0.00881	0.00975	0.01044	0.03303
		0.00662	0.00725	0.00796	0.00850	0.02548
		0.00516	0.00570	0.00636	0.00675	0.01911

O. R. Howell, J. Kendall and K. P. Monroe, G. Matsuo and co-workers, and N. A. Yajnik and R. L. Uberoy measured the viscosity of soln. in hydrochloric acid; M. R. Schmidt and H. C. Jones, of soln. in methyl alcohol, in ethyl alcohol, and in glycerol. G. Nagel discussed the surface phenomena of soln. of the salt.

H. Feudt found that the **specific heat** of soln. containing 16.4 per cent. of CoCl_2 is 0.767 between 15° and 49°, and 0.787 between 18° and 89°; and soln. with 8.9 per cent. of CoCl_2 , the sp. ht. is 0.865 between 15° and 49°, and 0.896 between 19° and 90°. The subject was studied by K. Jauch. W. Wrewsky measured the sp. ht. of soln. in ethyl alcohol. L. R. von Fellenberg, and C. Sandonnini said that cobalt chloride sublimes without fusing, and J. L. Proust, after fusing. A. Ferrari and co-workers gave 724° for the **melting-point** of anhydrous cobalt chloride, in a current of hydrogen chloride; H. Bassett and W. L. Bedwell gave 735°; and A. Ferrari, and A. Ferrari and A. Baroni noted that the presence of nickel chloride raises the m.p. W. Hempel and H. Thiele were unable to volatilize cobaltous chloride at ordinary press. or in vacuo; but W. Biltz and E. Birk found that the chloride first melts and then boils to furnish a pale blue sublimate, and the sublimation of cobalt chloride was discussed by A. Gorgeu, W. Spring, R. Rieth, and C. Winkler. According to L. R. von Fellenberg, cobalt chloride is volatile at a red-heat in a current of hydrogen chloride; and G. L. Clark and co-workers found that sublimation occurs below 500° in the presence of a little hydrogen chloride. C. G. Maier obtained 1049° for the **boiling-point** of the anhydrous chloride; and for the **heat of vaporization**, in Cals. per mol., by extrapolation of the vap. press.:

	1049°	1017°	972.4°	900.2°	805.2°	730.0°
Heat of vaporization . . .	30.61	29.70	28.52	25.75	22.41	20.19

K. Jellinek and R. Uloth calculated the dissociation pressure of cobalt chloride, $\text{CoCl}_2 \rightleftharpoons \text{Co} + \text{Cl}_2$, and obtained for the partial press. of the chlorine, p mm.:

	25°	400°	500°	600°
p	4.57×10^{-55}	9.55×10^{-18}	2.34×10^{-14}	6.61×10^{-12}

J. Bersch said that at 30° the red hexahydrate begins to turn blue in places, at 35° the whole mass appears dark blue, and at 35° to 39° it loses its lustre, and breaks up to form a mass of acicular crystals; if the product be melted and cooled, the original red mass of crystals is formed. J. Bersch gave 86·75° for the m.p. of the hexahydrate; this temp. appears to be too high, because W. Stortenbeker, and A. L. Potilitzin found that dry crystals melt at about 54°, a little higher than the transition temp. of the hexahydrate to the dihydrate. J. Bersch said that the melt may be undercooled to 50° without solidification. A. Hantzsch observed an incongruent m.p. at 35°. G. N. Wyrouboff studied the **dehydration** of the salt; he observed that the salt partially melts at 60° and then appears blue. If kept many hours at this temp., it gradually loses water, and becomes deeper blue. Under the microscope the salt then appears as a mixture of red crystals which have not melted, and opaque crystals of a lower hydrate, swimming in a soln. intensely blue. If the temp. rises to 80°, more water is given off, and when the weight is constant at this temp., the deep violet salt appears homogeneous, and it corresponds approximately with the monohydrate, and loses water only when the temp. rises to 135° to 140°. According to A. L. Potilitzin, the hexahydrate loses no perceptible quantity of water in an open tube, but it becomes turbid at 30° to 40°, and at 45° to 52° it rapidly effloresces, and after being kept 4 hrs. at this temp. its composition approximates to the rose-red dihydrate. In dry air, over sulphuric acid, at ordinary temp., the salt also passes slowly into the dihydrate. J. Bersch found that the red hexahydrate approximates to the tetrahydrate at 11°, and to the dihydrate at 121°. According to A. Hantzsch and F. Schlegel, J. Bersch, P. Sabatier, and E. J. Mills, the hexahydrate loses 4 mols. of water in a desiccator over sulphuric acid. H. Lescœur, and W. Müller-Erbach made observations on the vap. press. of the hydrates, and observed that no hydrate between the di- and hexa-hydrate exists at 20°. H. Lescœur gave 4·0 mm. for the vap. press. of the hexahydrate at 20°, and 14·9 mm. at 40°. According to H. Wessels, if a tube of compressed, powdered hexahydrate be warmed to 63° at one end, clear layers of the anhydrous salt, the dihydrate, and the hexahydrate, and water travel to the cold part of the tube.

C. G. Maier measured the **vapour pressure** of the anhydrous chloride, p mm., at different temp., and found at :

	633·3°	699·2°	799·1°	915·7°	957·7°	991·4°	1010·4°	1024·5°	1035·1°	1091·2°
p	121·4	145·9	211·4	364·9	484·4	604·1	685·4	764·8	829·6	1256·7

G. Tammann gave for the lowering of the vap. press. of aq. soln. by the dissolution of 6·05, 24·04, 41·47, and 57·69 grms. of salt per 100 grms. of water, respectively, 13·9, 75·2, 146·3, and 207·5 mm. G. Charpy obtained for the vap. press., p mm., of a 32 per cent. soln. of cobaltous chloride :

	21°	35°	40°	59°	70°	80°	88°
p	7	15	19	39	59	93	120 mm.

G. Charpy added that the corresponding curve includes to almost linear parts one ranging from 20° to 40° corresponding with the red soln., and the other, ranging above 75°, with the blue soln. The intermediate part is curved. The curves thus indicate the existence of two stable modifications of the salt—hydrates or other molecular aggregates. The curve is similar to the solubility curve of A. Étard, but the critical points do not coincide. Measurements were also made by R. E. Wilson, K. Jelinek and R. Uloth, R. Uloth, W. Geller, and N. Tarugi and G. Bombardini. M. Prud'homme studied the relation between the mol. wt. and the lowering of the vap. press. of aq. soln. I. H. Derby and V. Yngve, and C. Dieterici measured the vap. press. of the hydrated chloride, and of its sat. soln., and the results show that for sat. soln. of concentration, C , the vap. press., p mm., at θ , are :

	24·19°	28·68°	39·47°	49·23°	52·25°	56·44°	68·26°	78·87°
p	14·7	18·4	30·5	44·8	48·6	58·7	105·1	170·9
	$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$				$\text{CoCl}_2 \cdot 2\text{H}_2\text{O}$			

The results are plotted in Fig. 77. The transition temp. for $\text{CoCl}_2 \cdot 6\text{H}_2\text{O} \rightleftharpoons \text{CoCl}_2 \cdot 2\text{H}_2\text{O} + 4\text{H}_2\text{O}$ is 52.25° . No evidence of the existence of a tetrahydrate was observed; nor did the observations of H. Lescœur, on the vap. press. during the dehydration of the hexahydrate, show any evidence of the existence of the tetrahydrate.

F. Rüdorff gave for the **cryohydrates**—the ice-line on the solubility curve, Fig. 78—for soln. with 15.3 and 22.5 per cent. of CoCl_2 , respectively, -10.0° , and -20.0° . This does not fit F. Guthrie's value -15.3° for the **eutectic**, since the extrapolated value from the data of F. Rüdorff, and A. Étard, is -22.5° for soln. with 24 per cent. CoCl_2 . The **molecular weight** determinations of cobalt chloride in boiling pyridine, and piperidine, by A. Werner; in boiling quinoline, by E. Beckmann; and in boiling bismuth chloride, by L. Rügheimer, agree with the simple formula, CoCl_2 ; but in freezing urethane, N. Castor found that the results agreed with the doubled formula, Co_2Cl_4 ; but G. Bruni and A. Manuelli could not confirm this. The **lowering of the freezing-point** of aq. soln. was measured by R. E. Hall and W. D. Harkins, W. Biltz, A. Benrath, N. Tarugi and G. Bombardini, and H. C. Jones and co-workers. The results showed that a soln. with G grm. of CoCl_2 per 100 grms. of water had a f.p. of :

G	0.0225	0.1159	0.831	3.601	5.4775	11.691	25.98
F.p.	-0.00930°	-0.04575°	-0.325°	-1.3934°	-2.1900°	-5.420°	-19.000°

The **raising of the boiling-point** of aq. soln., measured by R. Salvadori, N. Tarugi and G. Bombardini, and A. Benrath, showed that soln. with 0.80, 2.23, and 7.88 grms. of CoCl_2 in 100 grms. of water, raised the b.p. respectively, 0.11 , 0.30° , and 1.0° . R. Salvadori, and O. E. Frivold measured the raising of the b.p. in methyl alcohol; A. Benrath, and O. E. Frivold, in ethyl alcohol; A. L. Robinson, in acetone; A. Werner, in pyridine; E. Beckmann, in quinoline; and L. Rügheimer, in bismuth chloride.

The **heat of formation** of anhydrous cobaltous chloride is, according to J. Thomsen, $(\text{Co}, \text{Cl}_2) = 76.48$ Cals; and, according to W. Biltz and W. Holverscheid, 74.8 Cals. The subject was studied by E. Rabinowitsch and E. Thilo, O. Schütz and F. Ephraim, F. Ephraim, and G. Devoto and A. Guzzi. J. Thomsen gave $(\text{Co}, \text{Cl}_2, \text{Aq.}) = 94.824$ Cals.; $(\text{Co}, 2\text{HCl}, \text{Aq.}) = 16.184$ Cals.; and for the **heat of neutralization**, $\{\text{Co}(\text{OH})_2, 2\text{HCl}, \text{Aq.}\} = 21.14$ Cals.; M. Berthelot gave $(\text{CoO}, 2\text{HCl}, \text{Aq.}) = 21.1$ Cals.; W. Biltz and W. Holverscheid, $(\text{Co}, 2\text{HCl}, 8.8\text{H}_2\text{O}) = 13.4$ Cals.; and F. Bourion, $4\text{CoO} + 4\text{S}_2\text{Cl}_2 = 4\text{CoCl}_2 + 2\text{SO}_2 + 6\text{S} + 124$ Cals. J. Bersch noted that cooling occurs when the hexahydrate is dissolved in water; and F. G. Donnan and H. Bassett, that heat is developed when a conc. aq. soln. is diluted. J. Thomsen gave for the **heat of solution** of the hexahydrate in 400 mols. of water at 18° , -2.85 Cals.; and P. Sabatier gave for the dihydrate, 9.85 Cals; and J. Thomsen, for the anhydrous chloride, 18.3 Cals. at 21.5° ; and J. Thomsen gave for the heat of hydration $(\text{CoCl}_2, 6\text{H}_2\text{O}) = 21.19$ Cals.; P. Sabatier, $(\text{CoCl}_2, 2\text{H}_2\text{O}, 4\text{H}_2\text{O}) = 6.95$ Cals.; and $(\text{CoCl}_2, 2\text{H}_2\text{O}) = 5.7$ Cals. G. Devoto and A. Guzzi calculated 41,900 cals. for the **free energy** of formation of the molten salt; and G. Beck, 255,000 cals. for the total energy of the reacting electrons. W. Klemm studied the relation between the lattice energy and the heat of formation.

A. Neuhaus gave for the **indices of refraction** of the dihydrate, $\alpha = 1.625$, $\beta = 1.671$, and $\gamma = 1.670$. H. C. Jones and F. H. Getman found the refractive indices of soln. with M mol. of the salt per litre :

M	0.0969	0.1279	0.1918	0.3197	0.4475	0.5114	0.6393
μ	1.32735	1.33005	1.33151	1.33518	1.33910	1.34064	1.34415

A. Bromer gave for soln. with P per cent. of cobaltous chloride, with the C -, D -,

FIG. 77.—Vapour Pressures of Hydrates and Saturated Solutions of Cobaltic Chloride.

and *F*-lines, at 20°, and the mol. refraction, *R*, with the μ^2 -formula, and the *D*-line:

<i>P</i>	μ_C	μ_D	μ_F	<i>R</i>
5.784	1.34473	1.34738	1.34801	17.94
0.082	1.33120	1.33345	1.33431	16.20

Observations were also made by J. Grailich, A. Heydweiller, L. R. Ingersoll, P. Vaillant, O. R. Howell, and G. Limann. A. Heydweiller made observations on the dispersion. J. H. Gladstone and W. Hibbert found the **molecular refraction**, with the μ formula, for soln. having 4.97, 9.47, 17.49, and 27.86 per cent. of cobalt chloride, to be respectively, 32.86, 32.77, 32.84, and 32.71 for the *H α* -line, and 33.53, 32.99, 33.12, and 32.97 for the *D*-line. F. W. O. de Coninck found that the red, aq. soln. becomes violet on exposure to sunlight; and that only six-tenths of the light transmitted by the red soln. is transmitted by the blue soln. Attempts to isolate the blue product were not successful.

R. A. Houstoun, and H. M. Vernon discussed the changes of colour which occur when aq. soln. of the salt are diluted, and the temp. is raised—*vide supra*, the colour of cobalt chloride. The anhydrous chloride is blue, like all co-ordinated, unsaturated cobalt salts; whereas co-ordinated, saturated salts are red. E. N. da C. Andrade observed that cobalt chloride in a flame containing chlorine, gives a **molecular spectrum** with bands in the green and blue. H. Fesefeldt studied the absorption spectrum of the thin layers of anhydrous chloride and observed characteristic bands between 200 and 240m μ . The absorption spectrum of aq. soln.—*vide supra*, the absorption spectrum of cobalt chloride—was observed by W. V. Bhagwat and N. R. Dhar, R. Brdicka, W. R. Brode, W. R. Brode and R. A. Morton, A. R. Brown, W. W. Coblenz and co-workers, F. L. Cooper, A. Cotton, G. Déniges, G. J. Elias, A. Étard, J. Formanek, J. Groh, A. Hantzsch, W. Hardt, W. N. Hartley, R. Hill and O. R. Howell, S. M. Karim and R. Samuel, R. A. Houstoun and co-workers, E. O. Hulbert and co-workers, T. Inoue, H. C. Jones and co-workers, J. von Koczkas, R. J. Macwalter and S. Barratt, C. Mazzetti, M. G. Mellon, B. E. Moore, A. Rosenheim and V. J. Meyer, W. J. Russell, S. B. Schwezoff and A. M. Tanchilewitsch, Y. Shibata and T. Inoue, G. Spacu and J. G. Murgulescu, O. Specchia, P. Vaillant, and H. W. Vogel. O. Stelling, and S. Aoyama and co-workers studied the **X-ray absorption spectrum**. O. Gossmann observed no **emission of ions** by cobaltous chloride at 450°. R. Robl observed no **luminescence** in ultra-violet light; and M. Trautz detected neither **crystallo-luminescence** nor **triboluminescence**, with the anhydrous salt nor with the hexahydrate.

R. W. Roberts and co-workers, F. Allison and E. J. Murphy, and E. Miescher found that the **magnetic rotation** of cobalt chloride is positive. R. Wasmuht gave 0.8224 for the sp. rotation, and 5.9215 for the mol. rotation of cobalt chloride in soln. containing 14.603 grms. of chloride per 100 c.c. with Na-light. G. J. Elias studied the results with hydrochloric acid soln. L. R. Ingersoll gave for **Verdet's constant**, with layers 1 cm. thick per gauss, with a soln. of sp. gr. 1.296 at 23°, 0.0096 and 0.0066 for light of wave-length, respectively, 0.8 and 1.0 μ . Observations were also made by E. Miescher, O. Schönrock, and M. Scherer. P. Krishnamurti studied the **Raman effect**.

W. Hampe found that the **electrical conductivity** of molten cobaltous chloride is very good—chlorine is evolved at the anode, and crystalline cobalt is deposited at the cathode. E. Franke gave for the mol. electrical conductivity, μ , of a soln. of a mol. of cobaltous chloride in *v* litres of water at 25°:

<i>v</i>	32	64	128	256	512	1024
μ	100.5	105.3	110.3	114.0	116.8	118.7

Observations were also made by W. Althammer, W. Hardt, A. Heydweiller, H. C. Jones and co-workers, C. Mazzetti, A. Rosenheim and V. J. Meyer, M. R. Schmidt and H. C. Jones, N. Tarugi and G. Bombardini, O. R. Howell, and J. Trötsch. The

limiting value of the conductivity at 18°, found by A. Heydweiller, is $\lambda_{\infty}=108$; W. Althammer gave 125.6 to 126.9 at 25°; and C. Mazzetti, 102 at 10°; 143 at 20°; 184 at 30°; 224 at 40°; 260 at 50°; and 289 at 60°. According to C. Mazzetti, if C denotes the number of gram-equivalents of cobalt chloride per litre, the eq. conductivity, λ , are:

C	0.251	0.752	1.504	2.006	7.631
λ	13° to 14°	.	.	.	0.0705	0.0605	0.0511	0.0460	0.0112
	34° to 35°	.	.	.	0.1058	0.0886	0.0742	0.0665	0.0174
	45° to 46°	.	.	.	0.1252	0.1040	0.0869	0.0777	0.0208
	59° to 60°	.	.	.	0.1465	0.1209	0.1012	0.0904	0.0249

Curves showing the relation between eq. conductivity show a point of inflexion which indicates that two distinct curves are involved, and that the phenomenon is due to a reduction in the degree of hydration of the ions as the concentration increases, so that the eq. conductivity falls less rapidly than would otherwise be anticipated. The results with mixed soln. of barium and cobalt chlorides are attributed to a decrease in the hydration of the ions as the concentration increases, and to the formation of complex anions. H. C. Jones and co-workers, J. Trötsch, E. Rimbach and K. Weitzel, and F. G. Donnan and H. Bassett studied the temp. coeff. of the conductivity.

The effect of temperature on the conductivity of the soln. of cobalt chloride was also studied by G. Dickhaus, and J. Hamacher; the results show breaks in the regularity of the curve between 31.4° and 31.5°, between 40.9° and 41.0°, and 47.6° and 47.7°. W. Geller, and G. Charpy also observed breaks in the curves for the vapour press. of the soln. H. F. Haworth studied the conductivity with alternating currents. O. R. Howell measured the electrical conductivity of soln. in hydrochloric acid; P. B. Davis and co-workers, soln. in formamide; W. Hardt, E. Rimbach and K. Weitzel, H. R. Kreider and H. C. Jones, and H. C. Jones and L. McMaster, soln. in methyl alcohol; and E. Rimbach and K. Weitzel, H. C. Jones and L. McMaster, A. Rosenheim and V. J. Meyer, B. Völlmer, M. R. Schmidt and H. C. Jones, and H. R. Kreider and H. C. Jones, soln. in ethyl alcohol. W. Hardt measured the equivalent conductivity, λ , of an eq. of cobalt chloride in v litres of alcohol at 20°, and obtained the results summarized in Table IV. He also

TABLE IV.—EQUIVALENT CONDUCTIVITIES OF MIXED SOLUTIONS OF COBALTOUS CHLORIDE IN ETHYL ALCOHOL AND WATER.

v	Percentage proportion of ethyl alcohol						
	100	85	70	50	40	30	0
1	2.0	6.5	10.7	17.6	21.0	24.8	63.2
2	2.3	8.8	13.7	20.5	24.5	30.7	72.5
4	2.7	11.1	16.7	23.2	27.9	35.6	80
8	3.15	13.1	19.2	25.6	30.9	39.7	87.2
16	3.8	15.1	21.7	27.9	33.4	43.2	92.8
32	4.7	17.1	24.0	30.5	35.7	45.3	96.8
64	6.0	19.2	26.1	31.7	37.2	47.2	102.0
128	7.5	21.0	27.8	33.1	38.4	48.9	105.6
256	9.2	22.6	29.1	34.3	39.6	50.3	107.6
512	10.7	23.8	30.2	35.3	40.4	51.2	109.8
1024	13.3	25.2	31.2	36.1	41.2	51.9	110.6
2048	16.6	26.1	31.8	36.7	41.8	52.5	110.8
4096	20.0	27	32.4	37.1	42.2	52.7	111.0

obtained results for methyl and amyl alcohols. The eq. conductivity of soln. in methyl alcohol is 32.2; in ethyl alcohol, 4.9; and in amyl alcohol, 0.057 under analogous conditions. F. Baur, E. Rimbach and K. Weitzel, H. C. Jones and L. McMaster, and M. Wien measured the electrical conductivity of soln. in acetone;

A. Hantzsch, S. von Laszczynsky and S. von Gorsky, A. T. Lincoln, and J. N. Pearce, of soln. in pyridine; and J. N. Pearce, of soln. in quinoline.

The **transport numbers** of the anion were found by W. Althammer for dilutions of a mol. of the salt, in v litres, at 18° , to be 0.6067 for $v=49.73$, 0.6010 for $v=98.19$, and 0.6016 for $v=193.4$. Observations were also made by W. Bein, E. Rona, and A. Kotschubey. C. Mazzetti found that the ratio of the mobility of the cobalt ion to the fluidity of water at the same temp. increases as the temp. rises from 10° to about 30° , and then diminishes regularly with rise of temp. This divergence is attributed to an independent increase in the value of the eq. conductivity, owing to the de-solvation of the cobalt ion. The increase in the transport number of the anion with increased concentration of the soln., is attributed in part to the formation of complex anions. H. G. Denham found the transport numbers, n , of cobalt, Co^{++} , in soln. of the chloride with C mols. CoBr_2 per litre, to be:

C	0.090	0.459	1.345	2.448	3.106	4.731	5.554
n	0.409	0.413	0.340	0.322	0.215	0.005	-0.444

The decreasing values and the negative value correspond with the formation of complexes CoBr_3^- and CoBr_4^{--} as increasing amounts of cobalt are transferred to the anode.

H. C. Jones and co-workers, and P. Vaillant calculated the degree of **ionization** of the salt in aq. soln. from electrical conductivity measurements. A. Günther-Schulze inferred that in conc. soln., the ionization proceeds: $\text{CoCl}_2 \rightleftharpoons \text{CoCl}^+ + \text{Cl}^-$; and in soln. with less than normal concentration, $\text{CoCl}_2 \rightleftharpoons \text{Co}^{++} + 2\text{Cl}^-$. For the factor i calculated from the lowering of the b.p., for soln. with C eq. of the salt per litre, R. E. Hall and W. D. Harkins observed:

C	0.005	0.01	0.02	0.05	1.00
i	2.858	2.802	2.749	2.687	2.650

Observations were also made by R. Salvadori; N. Tarugi and G. Bombardini calculated values from the lowering of the vap. press., and the ionization of the salt in aq. soln. was discussed by W. H. Banks and co-workers. G. N. Lewis and G. A. Linhart calculated the activity coeff. from observations on the f.p. of aq. soln. of C mol. of the salt in a litre of water and found for $C=10^{-2}$; 0.00943 for $C=10^{-4}$; and 0.00995 for $C=10^{-7}$. H. Ley inferred that the **hydrolysis** of aq. soln. is very small; and L. Bruner observed no hydrolysis at 40° by the method of sugar inversion. R. Engel observed some hydrolysis, and W. Althammer said that at 25° the hydrolysis: $\text{CoCl}_2 + \text{H}_2\text{O} \rightleftharpoons \text{CoCl}(\text{OH}) + \text{HCl}$ occurs to the extent of 0.12 per cent. for soln. with 0.05 mol. per litre, and 0.53 per cent. for soln. with 0.01 mol. per litre. C. Kullgren gave for soln. with $v=16$ and 64, a percentage hydrolysis of 0.0173 and 0.0147, respectively at 85.5° , and at 100° , of 0.0172 and 0.0196, respectively. H. G. Denham obtained a hydrolysis of 0.11 per cent. at 25° for $v=16$, and 0.17 per cent. for $v=32$. Observations were made by T. Katsurai, H. M. Vernon, and R. Brdicka. H. G. Denham measured the e.m.f. of the cell $(\text{Pt})\text{H}_2|\text{CoCl}_2 \text{ soln.}, \text{NH}_4\text{NO}_3 \text{ sat. soln.}|\text{N-KCl}, \text{Hg}_2\text{Cl}_2\text{-electrode}$ for a soln. of a mol of cobalt chloride in 0.5 litre of water, and calculated for the corresponding **H⁺-ion concentration**:

	26°	48°	67°	84.5°	91°	100°
Electromotive force . . .	0.4996	0.4917	0.4834	0.4659	0.4566	0.4382
H ⁺ -ion concentration $\times 10^3$.	0.213	0.523	1.064	2.612	3.945	7.943

The **solvation** of the salt in soln. was discussed in connection with the colour. H. C. Jones and co-workers calculated the degree of solvation, i.e. the degree of hydration of the salt, expressed as the number of mols. of water in combination with a mol. of the salt at the given concentration of M mols per litre when a litre of the soln., at that concentration contained 1000 grms. of water; and found:

M	0.025	0.075	0.100	0.500	1.00	1.50	2.00
Hydration . . .	152.88	33.68	34.13	27.86	24.14	21.1	17.88

H. J. Blikslager studied the formation of complex ions in the electrolysis of soln. of the cobalt chloride in fused alkali chlorides; and R. Böttger, and G. Gore, the **electrodeposition** of cobalt from soln. of cobalt salts—*vide supra*. G. Devoto and A. Guzzi found that the **decomposition potentials**, E volt, of the molten salt, at different temp., are:

	750°	800°	850°	900°
E	0.948	0.914	0.882	0.860

M. le Blanc found the decomposition tension of $N\text{-CoCl}_2$ is 1.78 volt. R. Brdicka found the decomposition potential of cobalt from blue soln.—*vide supra*, deposition potential of cobalt—is greater than with pink soln., indicating a greater activity of the Co^{++} -ions in blue soln. W. Althammer found the **electromotive force** of the cell $(\text{Pt})\text{H}_2|\text{CoCl}_2 \text{ soln.}|\text{KCl}_{\text{sat. soln.}}|0.1N\text{-KCl}, \text{Hg}_2\text{Cl}_2|\text{Hg}$ to be constant after about half an hour, and to be 0.579 volt with 0.05M-CoCl₂, and 0.583 volt with 0.01M-CoCl₂. T. Svensson studied the cell $\text{Pt}|0.1M\text{-CoCl}_2|N\text{-KCl}|\text{Hg}$; and H. G. Denham, the cell indicated above. G. Tammann and H. O. von Samson-Himmelsjerna studied the potential of cobalt soln. of the chloride. The electrolysis of conc. aq. soln. of cobaltous chloride with platinum electrodes was found by J. H. Paterson to furnish cobalt metal, and with dil. soln., and low current densities, cobalt hydroxide; and M. le Blanc found that with $N\text{-CoCl}_2$, and a current of 1.78 volts, the platinum anode acquires a film of cobalt peroxide. C. Schall studied the anodic oxidation of soln. of cobaltous salts—*vide supra*, the electrodeposition of cobalt; and G. N. Lewis and G. A. Linhart, and K. Hess and K. Jellinek, the activity coeff. H. N. Holmes studied the **electrostenolysis** of soln. of cobalt chloride; and A. L. T. Moesveld and H. J. Hardon, the **electrostriction** of aq. soln. of cobalt salts.

G. Wiedemann measured the **magnetic susceptibility**, χ mass unit, of anhydrous cobalt chloride. The salt is paramagnetic. P. Théodoridès gave 96.29×10^{-6} when corrected for the diamagnetism of the Cl^- -ions; and T. Ishiwara, and K. Honda and T. Ishiwara gave for a field-strength of 2000 grms.:

	-81.4°	-16.7°	15.0°	90.6°	157.3°	308.4°	527.2°	686.1°
$\chi \times 10^6$	151.1	108.9	95.3	72.9	60.4	43.5	30.3	24.7

Observations were also made by R. Mercier, L. A. Welo, S. S. Bhatnagar and A. N. Kapur, H. R. Woltjer and H. K. Onnes, and A. Chatillon. H. R. Woltjer extrapolated the curve and gave -253° for the Curie point; P. Théodoridès, -225.8° ; and T. Ishiwara, and K. Honda and T. Ishiwara, -240° . The effect of field-strength was measured by H. R. Woltjer, M. Wien, and H. R. Woltjer and H. K. Onnes, who found the magnetization curve at low field-strength is converse towards the H-axis, and at high field-strengths, it is linear. Observations were also made by P. Théodoridès, and B. Cabrera. A. Cotton studied the magnetic dichroism.

A. Chatillon found that the hexahydrate is paramagnetic; and that the susceptibility at different temp. is:

	-79°	0°	15°	40°	135.2°	153.5°	183.5°	208.5°
$\chi \times 10^6$	59.58	43.85	41.75	38.68	30.55	29.23	27.166	25.73
	Solid				Molten			

There is an abrupt rise of about 10 per cent. at about 55° , when the hexahydrate changes into the dihydrate. The Curie point with the hexahydrate is about -260° . W. Klemm and W. Schüth found the magnetic susceptibility at 293°K. , 493°K. , and 673°K. to be, respectively, $\chi \times 10^6 = 95, 52$, and 37. S. Meyer observed no remanent magnetization; and G. Roasio found that the crystals grown in a magnetic field are orientied, so that the C -axes are in the direction of the lines of force; and D. Samuracas, that the crystallization of the salt in aq. soln. is accelerated in a magnetic field.

M. Faraday noted that aq. soln. of moderate concentration are paramagnetic; and A. Quartaroli showed that soln. with 8.596 grms. of CoCl_2 per litre, are

non-magnetic, and with greater dilutions, the diamagnetism of the water predominates. O. Liebknecht and A. P. Wills gave 81×10^{-6} mass unit for the magnetic susceptibility of soln. of cobalt chloride; G. Quincke, 101×10^{-6} at 18° to 22° ; G. Jäger and S. Meyer, 81.5×10^{-6} at 18° ; and G. Falckenberg, 79.4×10^{-6} . Observations were also made by L. Brant, S. Datta, G. Falckenberg and R. Oppermann, H. Fahlenbrach, G. Föex, A. Lallemand, P. Pascal, P. Vaillant, G. Wiedemann, and E. C. Wiersma. According to A. Chatillon, the sp. magnetic susceptibility of a 19.94 per cent. soln. of cobalt chloride is $\chi_{\text{soln.}}$ mass unit, and the calculated value for the contained CoCl_2 is χ :

	12.8°	33.6°	61.3°	99.8°	116.1°	135.6°
$\chi_{\text{soln.}} \times 10^{-6}$	15.734	14.650	13.428	12.027	11.514	10.941
$\chi \times 10^{-6}$	81.80	76.35	70.23	63.20	60.63	57.81

B. Cabrera and co-workers found with C grms. of CoCl_2 per gram of soln., the mol. susceptibility at about 22° to 23° :

C	0.3206	0.04903	0.02905	0.01095	0.00628	0.00525
$\chi_{\text{mol.}} \times 10^{-6}$	10,141	10,163	10,263	10,374	10,191	10,026

A. E. Oxley gave for soln. with C grm. of CoCl_2 per c.c. at 17.4° the vol. susceptibility, κ vol. unit:

C	0.00622	0.00465	0.00311	0.00207	0.00155	0.00039
$\kappa \times 10^{-6}$	-0.251	-0.370	-0.500	-0.630	-0.630	-0.772

G. Wiedemann, G. Quincke, and G. Jäger and S. Meyer studied the influence of temp. on the susceptibility. The observations of L. Brant, G. Falckenberg and R. Oppermann, G. Jäger and S. Meyer, and A. E. Oxley show that the variation of the susceptibility with the conc. is linear; B. Cabrera and co-workers observed an increase with dilution up to a maxima with 0.00931 grm. per c.c., and then a decrease. P. Vaillant, and A. Quartaroli also noted a deviation from the linear relation. A. Trümpler, and A. Lallemand observed that the magnetic susceptibility of soln. of cobaltous chloride varies with concentration, and that the Curie points for concentration 0.072 to 0.0125 grm. of CoCl_2 per gram of soln. rise from -18° to -7° . A. Chatillon found that the ageing of the soln. altered the susceptibility, but not so with A. Trümpler, and P. Weiss. B. Cabrera and co-workers observed that soln. prepared in the cold give different values from soln. prepared hot. P. Vaillant, and B. Cabrera and co-workers attributed the increase of susceptibility with dilution to the increasing ionization. A. Chatillon suggested that the change is due to an unstable magnetic state of the cobalt ions, and that the stable state is acquired only after the lapse of some 5 months. G. Quincke's statement that the susceptibility depends on the field-strength is, according to H. E. J. G. du Bois, based on an experimental error. G. Jäger and S. Meyer observed that the susceptibility is independent of the field-strength between 10,000 and 18,000 gauss; and L. Brant, between 3000 and 14,000 gauss for dil. soln., and 3000 and 10,000 gauss for conc. soln. P. Weiss, L. Brant, B. Cabrera and co-workers, A. Chatillon, G. Föex, A. Quartaroli, and P. Weiss and G. Föex discussed the magneton numbers; P. Pascal, A. E. Oxley, A. Chatillon, and B. Cabrera and co-workers studied the magnetic properties of soln. in hydrochloric acid; A. Quartaroli, in methyl alcohol; A. Quartaroli, and A. Chatillon, in ethyl alcohol; A. Chatillon, and W. Hardt, in normal amyl alcohol; A. Quartaroli, H. A. Curtis and R. M. Burns, and R. E. Wilson, in *iso*-amyl alcohol; and A. Quartaroli, in acetone. W. Sucksmith studied the gyromagnetic effect.

Chemical properties of cobalt chloride.—W. Spring observed that moist hydrogen reduces the red-hot chloride to metal; dry hydrogen does not reduce the chloride so readily, and there is then a partial sublimation of cobalt chloride—*vide supra*, the preparation of cobalt. F. de Carli compared the reducibility of the chloride with that of other metal chlorides. K. F. Bonhoeffer did not detect the reduction of cobaltous chloride by activated hydrogen. K. Jellinek and R. Uloth observed that at atm. press., the values for $K = P_{\text{HCl}}/P_{\text{H}_2}$ at 400° , 500° ,

and 600° , are, respectively, 0.110, 0.800, and 4.40. G. Crut found that the reaction with hydrogen is reversible: $\text{CoCl}_2 + \text{H}_2 \rightleftharpoons \text{Co} + 2\text{HCl}$, and the equilibrium constant, $K = Q/4.571T + \log p + \log [\text{HCl}]^2/[\text{H}_2]$, where p is the equilibrium pressure, and Q the heat of reaction, which is 32.0 cal. at 15° . At 445° , $K = 10.9$. J. H. Weibel studied the reaction. S. Miyamoto noted the chloride is reduced by hydrogen in the silent discharge. According to L. R. von Fellenberg, anhydrous cobalt chloride turns red a few minutes after exposure to **air**, owing to the absorption of moisture and the consequent formation of red hexahydrate. It is not affected by dry air. The blue hydrates also become red on exposure to air, and pass into the red hexahydrates. The red hexahydrates do not deliquesce on exposure to air. A. L. Potilitzin suggested that the cobaltous chloride in moist air passes first into the dihydrate, and more slowly into the hexahydrate; and F. W. O. de Coninck, that the tetrahydrate is formed at an intermediate stage in the hydration. J. Bersch said that the hexahydrate is stable in moist air; and A. L. Potilitzin, that it does not lose water in air at ordinary temp.; P. Sabatier, and J. C. G. de Marignae, that it deliquesces in moist air. A. L. Potilitzin found the dihydrate and the monohydrate are very hygroscopic. A. Ditte said that the crystals of the monohydrate become cloudy on exposure to air and break up into a rose-red powder. W. N. Hartley studied the deliquescence of the salt; and M. A. Razukin, the efflorescence of the hydrates. H. Schulze observed that when calcined in **oxygen**, or in air, black, crystalline cobaltous chloride is formed. H. Lescœur said that the formation of a basic chloride begins below 180° . K. Jellinek and A. Rudat observed that the action of oxygen on cobaltous chloride furnishes cobaltous oxide free from chlorine: $3\text{CoCl}_2 + 2\text{O}_2 \rightleftharpoons \text{Co}_3\text{O}_4 + 3\text{Cl}_2$. The vol. percentages of chlorine obtained at different temp. are:

	300°	350°	400°	500°	600°
Cl_2	1.12	1.0	1.9	11.3	47.0 per cent. by vol.

A. Mailfert studied the action of **ozone**. Anhydrous cobalt chloride dissolves in **water** very slowly, but, as indicated above, the chloride which has been exposed to air quickly dissolves in water. Observations on the solubility of the salt in water were made by R. Engel, A. Ditte, L. R. von Fellenberg, D. N. Bhattacharyya and N. R. Dhar, C. F. Bucholz, P. Sabatier, B. Franz, W. Stortenbeker, J. Bersch, etc. A. Étard found for the percentage solubility:

	-20°	-10°	0°	10°	20°	40°	50°	60°	80°	100°	120°
S	25.1	27.0	28.8	31.0	33.3	39.4	48.3	48.4	49.0	50.7	53.5
	$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$							$\text{CoCl}_2 \cdot 2\text{H}_2\text{O}$			

The cryohydrates and eutectics have been previously discussed. The corresponding solubility curve is shown in Fig. 78. A. L. Potilitzin gave 50° for the transition point $\text{CoCl}_2 \cdot 6\text{H}_2\text{O} \rightleftharpoons \text{CoCl}_2 \cdot 2\text{H}_2\text{O} + 4\text{H}_2\text{O}$; A. Chatillon gave 55° ; and I. H. Derby and V. Yngve, 52.25° . H. W. Foote found that a sat. soln. of the hexahydrate at 0° has 31.66 per cent. of CoCl_2 , and at 25° , 35.67 per cent.; C. Mazzetti gave 34.98 per cent. at 20° , and 51.93 per cent. at 98° ; A. Benrath gave 34.86 per cent. at 20° , and 36.30 per cent. at 25° ; and Y. Osaka and T. Yaginuma, 36.08 per cent. at 25° . W. W. Lucasse and H. J. Abrahams studied the action of the solvents glycol, pyridine, and methyl alcohol on the transition points.

The observations of H. G. Denham, R. Brdicka, and C. Kullgren on the hydrolysis of the chloride in aq. soln. have been already discussed. Basic salts have been reported. J. Habermann dropped dil. aq. ammonia into a boiling soln. of neutral cobalt chloride and obtained a peach-red precipitate of **cobalt hexahydroxydichloride**, $3\text{Co}(\text{OH})_2 \cdot \text{CoCl}_2$ or $\text{Co}_2(\text{OH})_3\text{Cl}$, which, after drying, was rather hygroscopic but sparingly soluble

FIG. 78.—The Solubility Curve of Cobaltous Chloride.

in water. W. Feitknecht said that the X-radiograms show that the lattice contains alternate layers of hydroxide and normal salt. J. C. Duff and E. J. Bills obtained the salt by the action of hexamethylene tetramine on a soln. of cobaltous chloride. E. Hayek obtained **cobalt hydroxychloride**, $\text{Co}(\text{OH})\text{Cl}$. W. Meigen prepared the *pentahydrate*, $3\text{Co}(\text{OH})_2 \cdot \text{CoCl}_2 \cdot 5\text{H}_2\text{O}$, by the prolonged action of calcite or aragonite on a soln. of cobalt chloride. A. Werner discussed the constitution of this salt. C. W. Stillwell obtained a salt with a definite X-radiogram by treating an excess of a soln. of cobalt chloride with potash-lye, and allowing the mixture to stand some time. A. L. Potilitzin obtained a basic chloride by heating the hydrated chloride in air at 100° to 120° , and H. Lescœur, at 120° ; and F. Reitzenstein obtained **cobalt oxydichloride**, $\text{CoO} \cdot \text{CoCl}_2$, by heating $\text{CoCl}_2 \cdot \text{C}_5\text{H}_5\text{N} \cdot \text{C}_5\text{H}_6\text{Cl}$ in an air-bath at 150° . F. Reiff described the oxychloride $[\text{CoCl}_2(\text{H}_2\text{O})(\text{HO})]\text{H} \cdot \text{C}_4\text{H}_8\text{O}_2$. According to A. Bernardi, with cold, dil. soln. of cobaltous chloride and sodium hydroxide, a blue basic salt is precipitated which soon turns green. The formation of the green salt depends on the proportions of the cobaltous salt and sodium hydroxide, and is formed only when the mol. ratio $\text{NaOH} : \text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ is between the limits 0.02 to 0.44. The phenomenon depends on the formation of an oxidation product. A. C. Robertson, and A. von Kiss and F. E. Lederer studied the catalytic decomposition of **hydrogen dioxide** by cobalt chloride.

O. Ruff observed that **fluorine** at ordinary temp. converts the chloride into fluoride; A. Classen and B. Zahorsky, that liquid **chlorine** has no action on the anhydrous chloride; and A. L. Potilitzin, that when the chloride is heated with an equivalent of **bromine** in a sealed tube at 400° , approximately 3.82 per cent. of chlorine is displaced. R. Weinland and F. Schlegelmilch prepared orange-red crystals of hydrated **cobaltous bisiodotrichloro-chloride**, $\text{CoCl}_2 \cdot 2\text{ICl}_3 \cdot 8\text{H}_2\text{O}$, by the action of **iodine trichloride** on a soln. of cobalt chloride. C. Poulenc found that cobalt chloride is decomposed by **hydrogen fluoride** at room temp., and G. Gore said that the salt is insoluble in liquid hydrogen fluoride. A. Ditté reported that when **hydrogen chloride** is passed into conc. soln. of cobalt chloride, the monohydrate or the hemitrihydrate (*q.v.*) may be formed. R. Engel said that the dihydrate is converted into the anhydrous salt by hydrogen chloride at ordinary temp. N. Isgarischeff, and S. Schapiro studied the accelerating action of the chloride when **hydrochloric acid** acts on marble. P. Sabatier found that with increasing proportions of hydrochloric acid in aq. soln., the solubility of cobalt chloride first decreases and then increases. Expressing solubilities in eq. of acid and salt per 100 eq. of water, he found, at 19° :

HCl	0	1.99	9.16	12.41	16.24
CoCl_2	7.777	6.13	3.29	4.57	4.70
Sp. gr.	1.397	1.307	1.256	1.290	1.314

The last soln. evolves hydrogen chloride when exposed to air, and deposits amethyst-blue needles of a lower hydrate, and when cooled it deposited a blue, granular precipitate which decomposed so readily that it could not be analyzed. It was thought to be a **cobalt hydrochloride**. R. Engel also obtained blue, deliquescent crystals of what was thought to be a hydrochloride, by cooling to -23° a soln. saturated with hydrogen chloride and cobalt chloride. He thought that the unstable product might be $\text{CoCl}_2 \cdot \text{HCl} \cdot 2(\text{or } 3)\text{H}_2\text{O}$. H. W. Foote studied the ternary system: $\text{CoCl}_2\text{--HCl--H}_2\text{O}$ at 0° , and found that only the hexa- and dihydrates were present as stable solid phases. There was no evidence of the formation of a hydrochloride. Expressing concentrations in grams per 100 grms. of sat. soln. at 0° , he found:

CoCl_2	31.66	25.58	5.97	2.69	11.58	12.42	12.66	15.12
HCl	0.00	3.26	19.01	25.66	28.97	29.84	30.27	33.86
Solid phase	$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$					$\text{CoCl}_2 \cdot 2\text{H}_2\text{O}$		

The results are plotted in Fig. 79. H. Bassett and H. H. Croucher were unable to obtain any compound with hydrogen chloride, even at temp. down to -20° with soln. sat. with the gas at atm. press., though with higher gas pressures a compound of the type $\text{CoCl}_2 \cdot \text{HCl} \cdot 3\text{H}_2\text{O}$ might be formed, analogous with the lithium salt of A. Chassevant, $\text{CoCl}_2 \cdot \text{LiCl} \cdot 3\text{H}_2\text{O}$, and in accord with the work of F. G. Donnan and H. Bassett on the complex anions in soln.—*vide supra*—the lithium salt might be $[\text{Li}(\text{H}_2\text{O})_2][\text{Co}(\text{H}_2\text{O})\text{Cl}_3]'$, which would agree with the further assumption that the blue anion is $[\text{Co}(\text{H}_2\text{O})\text{Cl}_3]'$. H. Bassett and H. H. Croucher found at 25° :

CoCl_2	35.87	28.54	12.77	15.50	18.50	18.18	17.55	21.00
HCl	0.00	5.29	20.50	22.51	22.85	23.45	26.72	31.10

Solid phase

 $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ $\text{CoCl}_2 \cdot 2\text{H}_2\text{O}$

They represent the hexahydrate, $[\text{Co}(\text{H}_2\text{O})_6]\text{Cl}_2$, and the dihydrate, $[\text{Co}(\text{H}_2\text{O})_4]\text{CoCl}_4$. R. Engel, and J. Kendall and K. P. Monroe measured the sp. gr. of hydrochloric acid soln. of cobaltous chloride; O. R. Howell, J. Kendall and K. P. Monroe, and N. A. Yajnik and R. L. Uberoy, the viscosity; E. Rona, the diffusion; O. R. Howell, the surface tension, and the indices of refraction; G. J. Elias, the magnetic rotation of the plane of polarization; W. R. Brode, G. Denigès, R. Engel, and O. R. Howell, the colour, and absorption spectrum; F. G. Donnan and H. Bassett, and H. Bassett and H. H. Croucher, the constitution of the soln.; O. R. Howell, the electrical conductivity; A. E. Oxley, P. Pascal, A. Chatillon, and B. Cabrera and co-workers, the magnetic properties; and B. Cabrera and co-workers, and A. Chatillon, the magneton numbers.

FIG. 79.—Ternary System: CoCl_2 —HCl— H_2O , at 0° and 25° .

According to A. J. Balard, and E. and B. Klimenko, anhydrous cobalt chloride with **hydrochlorous acid** gives a precipitate of hydrated cobaltic oxide, and chlorine is evolved. A. W. Ralston and J. A. Wilkinson, W. Biltz, and E. Keunecke found that anhydrous cobalt chloride is insoluble in liquid **hydrogen sulphide**. J. Myers said that when cobalt chloride is heated with **potassium sulphide**, cobalt, and alkali polysulphide are formed. C. Dufraisse and D. Nakae studied the effect on the oxidation of a soln. of **sodium sulphite**. H. L. Haken studied the action of **hyposulphites** on cobalt salt soln. A. Vogel observed that when cobalt chloride is treated with **sulphuric acid**, oxygen is evolved even in the cold. F. Ephraim said that with conc. sulphuric acid, hydrogen chloride is evolved at ordinary temp. A. Hantzsch and H. Carlsohn studied the action of dil. sulphuric acid. F. J. Faktor observed that when triturated with **sodium thiosulphate**, cobaltous chloride becomes green, and when the mixture is heated, molten sodium cobalt sulphide, $\text{Na}_2\text{Co}_4\text{S}_6$, is formed. C. R. Wise found that 100 grms. of a sat. soln. in **selenium oxychloride** contain 0.17 grm. of CoCl_2 at 25° .

G. Gore, and E. C. Franklin and C. A. Kraus noted that anhydrous cobalt chloride is insoluble in liquid **ammonia**; and E. Divers, that it swells up in a soln. of ammonium nitrate in ammonia. T. Vorster observed that when cobalt chloride is heated in ammonia gas, it is reduced to metal, but H. Rose, and F. Rose, etc., observed that at ordinary temp. the anhydrous chloride absorbs ammonia gas, producing a voluminous, pale pink powder of an ammine. The existence of four aminochlorides have been definitely established—the deca-, hexa-, and di-, and mono- amines—and G. L. Clark and co-workers announced a yellowish-red **cobaltous pentamminochloride**, $\text{CoCl}_2 \cdot 5\text{NH}_3$, of sp. gr. 1.580, to be formed by passing ammonia into a soln. of cobalt chloride in absolute alcohol; a rose-red

cobaltous aquopentamminochloride, $\text{CoCl}_2 \cdot 5\text{NH}_3 \cdot \text{H}_2\text{O}$, of sp. gr. 1.559, by passing ammonia into an aq. soln. of cobalt chloride at -10° ; and a **cobaltous tetramminochloride**, $\text{CoCl}_2 \cdot 4\text{NH}_3$, of sp. gr. 1.593, by H. Rose, by passing ammonia over dry cobalt chloride, and by G. L. Clark and co-workers, by keeping the hexammine in vacuo at room temp., or over sulphuric acid at 50° for 36 hrs., or by heating the

FIG. 80.—The Heating and Cooling Curves of Cobaltous Hexamminochloride.

the anhydrous chloride respectively in ammonia at 1 atm. press. is indicated in Fig. 80. The irreversibility of the composition-temperature curves in the region between the diammine and the hexammine is taken to be the result of the formation of solid soln. by the decomposing hexammine. The co-ordination and structure were discussed by P. C. Ray.

G. L. Clark and co-workers obtained **cobaltous decamminochloride**, $\text{CoCl}_2 \cdot 10\text{NH}_3$, by the action of ammonia gas on flocculent cobaltous chloride at a low temp. The brown product has a sp. gr. of 1.71, and on standing it passes into the hexammine. This may be the same as the pale rose-red decammine prepared by W. Biltz and C. Messercknecht. The crystalline hexammine takes up very little ammonia under the same conditions. W. Biltz found the dissociation press. of the decammine to be 25.5 mm. at -78.5° , 56.0 mm. at -70° , 87.0 mm. at -65° , 131.5 mm. at -60° , and 190 mm. at -55° . The heat of formation from the hexammine is 7.20 Cals. per mol. of NH_3 , and from CoCl_2 , 12.02 Cals. per mol. of ammonia.

E. Frémy prepared **cobaltous hexamminochloride**, $\text{CoCl}_2 \cdot 6\text{NH}_3$, by dissolving the greenish-blue precipitate produced by ammonia on conc. soln. of cobalt chloride in an excess of ammonia, and with the exclusion of air. The soln. furnishes pale rose-red octahedra of the hexammine. F. Rose recommended pouring the conc. soln. of cobalt chloride into conc. aq. ammonia, dissolving the precipitate by heating the soln., and allowing the filtered soln. to stand for some hours, when crystals of the hexammine are formed. A. Naumann and J. Rill obtained the salt in an analogous manner, and also by passing dry ammonia into a soln. of cobalt chloride in methyl acetate. A. Naumann and E. Vogt used acetone as solvent; and G. L. Clark and co-workers, and W. Biltz and B. Fetkenheuer, alcohol. J. Bersch,

FIG. 81.—The Arrangement of Atoms about Each Cobalt Atom of Cobaltous Hexamminochloride.

obtained the hexammine by passing ammonia over dry cobalt chloride. The octahedral crystals vary from flesh-red to red, according to the mode of preparation; P. Stoll found that the X-radiograms corresponded with a cubic lattice of the calcium fluoride type. The lattice parameter $a=9.87\text{Å}$. There are 4 mols. in the elementary cell. The cobalt atoms are located at the corners and the centres of the faces of a cube. Each cobalt atom is surrounded by six NH_3 -groups arranged at the corners of an octahedron, the cobalt atoms are at the corners of an octahedron, and the chlorine atoms at the corners of a cube. W. Biltz and E. Birk gave $a=10.12\text{Å}$; and G. B. Naess and O. Hassel, 10.10 Å., and 4.37 Å. for the distance between the Co and Cl atoms. The arrangement about each cobalt atom is shown in Fig. 81. G. L. Clark and co-workers found the sp. gr. to be 1.497 at $25^\circ/4^\circ$, and W. Biltz and co-workers

gave 1.479 at $25^{\circ}/4^{\circ}$; mol. vol., 156.9; mol. vol. of each of the six ammonia mols., 19.67. G. Beck studied the subject. The decomposition of the salt prevents a determination of the m.p. The dissociation press., p mm., is:

	82.5°	92.5°	101.5°	111.0°	118°	126°	132°	136°	139.5°
p	75	101	156	231	305	425	538	620	703

These results by F. Ephraim are considered by W. Biltz and B. Fetkenheuer to be too low. W. Biltz gave the results summarized in Fig. 82, for the stability ranges of the amines. W. Peters also made some observations on the subject. F. Ephraim measured the dissociation press. of mixtures of cobalt and nickel hexamminochlorides. G. Beck gave 323 cal. for the heat of formation. W. Biltz and B. Fetkenheuer calculated the heat of formation of the hexammine from the diamminochloride to be 14.5 Cals. per mol. of NH_3 ; and W. Biltz and G. F. Hüttig, 12.9 Cals. per mol. of NH_3 ; and W. Biltz obtained nearly 15.5 Cals. per mol. of NH_3 for the heat of formation from cobalt chloride and ammonia. L. Pauling and M. L. Huggins investigated the magnetic properties. The subject was studied by G. L. Clark, H. von Sanden, W. Hieber and E. Levy, and W. Hieber and F. Mühlbauer. A. B. Lamb and A. T. Larson found the equilibrium constant for the ionization: $[\text{Co}(\text{NH}_3)_6]^{++} \rightleftharpoons \text{Co}^{++} + 6(\text{NH}_3)$ is 1.25×10^{-5} . F. Rose noted that the hexammine oxidizes when exposed to air, and particularly so if the hexammine is moist. W. Gluud and co-workers studied the oxidation of the hexammine. E. Frémy found that the hexammine is hydrolyzed by water, to form a green, basic salt, but it dissolves without decomposition in conc. aq. ammonia. F. Rose added that the salt is freely soluble in dil. aq. ammonia, less soluble in conc. aq. ammonia, and insoluble in alcohol. N. S. Kurnakoff observed that a complex salt is formed with platinous chloride, $\text{Co}(\text{NH}_3)_6\text{Cl}_2 \cdot \text{PtCl}_2$.

FIG. 82.—Dissociation Pressures of the Cobaltous Diamminochlorides.

F. Rose prepared **cobaltous diamminochloride**, $\text{CoCl}_2 \cdot 2\text{NH}_3$, by heating the hexammine to 120° ; G. L. Clark and co-workers, and W. Biltz and B. Fetkenheuer, by exposing the hexammine in vacuo over conc. sulphuric acid, at 65° to 67° ; A. Naumann and E. Vogt, by passing ammonia into a soln. of cobalt chloride in acetone, or, according to A. Naumann and J. Rill, into a soln. of the chloride in methyl acetate. There are two forms of the diammine. The bluish-violet one just indicated is the *unstable* or β -form, or the *trans*-form. The rose-red salt—the *stable* or α -form or the *cis*-form—was obtained by W. Biltz and B. Fetkenheuer by passing dry ammonia over the hexammine at about 137° ; and by G. L. Clark and co-workers by passing dry ammonia into a boiling soln. of cobalt chloride in dry amyl alcohol. According to G. L. Clark and co-workers, the pale rose-red product has a sp. gr. of 2.097 at $25^{\circ}/4^{\circ}$, a mol. vol. of 78.25, and the mol. vol. of the ammonia is 19.77. W. Biltz and B. Fetkenheuer gave 273° for the m.p., and for the dissociation press., p mm.:

	136.5°	153.5°	168.0°	183.5°	230°	234°	236°
p	6.9	13.3	27.0	42.5	82.4	85.2	89.9

The heat of formation from the monammine, calculated by W. Biltz and B. Fetkenheuer, is 18.67 Cals., and from cobalt chloride, it is 19.88 Cals. per mol. of NH_3 . The subject was discussed by G. L. Clark, and W. Hieber and E. Levy. W. Biltz found that the sp. magnetic susceptibility of the α -form is 76×10^{-6} mass unit, and of the β -form, 74×10^{-6} mass unit. When the β -form is heated to 210° in dry ammonia, it passes into the α -form; the dissociation press. of the β -form at 216° is 14.5 mm. lower than that of the α -form. The α -form is rose-pink, the β -form is blue. The β -form is more sensitive than the α -form to water, and water vapour. W. Klemm and W. Schüth studied the magnetic susceptibility. The structure was discussed by A. Hantzsch. W. Biltz and B. Fetkenheuer assume

that the α -form is cobaltous cis-diamminochloride, and the β -form is cobaltous trans-diamminochloride :

(cis- or α -form)Trans- or β -form

G. L. Clark and co-workers heated a mixture of cobalt chloride and its hexammine in theoretical proportions in a sealed tube at 230° , and obtained **cobaltous monamminochloride**, $\text{CoCl}_2 \cdot \text{NH}_3$. W. Biltz and B. Fetkenheuer obtained it by heating the hexammine in vacuo at 230° . The violet-blue powder melts at 321° , its dissociation press. at 208° , 215° , and 210° are, respectively, 2.86, 3.76, and 8.05 mm. The heat of formation from ammonia and cobalt chloride is about 21.2 Cals.

F. W. Bergstrom observed that no definite product is formed by the action of **potassium amide** on a soln. of cobaltous chloride in liquid ammonia. T. W. B. Welsh and H. J. Broderson found that 100 grms. of anhydrous **hydrazine** dissolve about a gram of anhydrous cobalt chloride at about 15° ; and C. Paal and L. Friederici observed no reduction at 100° . H. Franzen and O. von Mayer prepared **cobaltous dihydrazinochloride**, $\text{CoCl}_2 \cdot 2\text{N}_2\text{H}_4$, by heating a mixture of cobaltic chloropentamminochloride, hexamminochloride, or aquopentamminochloride and 50 per cent. hydrazine hydrate on a water-bath. T. Curtius and L. Guttman obtained the complex salt by treating a soln. of thoroughly dried cobalt chloride in absolute alcohol with anhydrous hydrazine; or hydrazine hydrate. W. Hieber and co-workers studied the energy of formation. According to H. Franzen and O. von Mayer, the rose-red powder is insoluble in cold water, but it is hydrolyzed by boiling water; it is soluble in dil. acids and in aq. ammonia; and when heated in an atm. of carbon dioxide, it forms anhydrous cobaltous chloride. P. C. Ray and H. Bhar found the magnetic susceptibility to be 48.7×10^{-6} mass unit; and D. M. Bose discussed the magnetic properties of the complex salts. A. Ferratini obtained **cobaltous pentahydrazinooctochloride**, $2\text{CoCl}_2 \cdot 4\text{N}_2\text{H}_5\text{Cl} \cdot \text{N}_2\text{H}_4$, by mixing an aq. soln. of the components, and boiling the product with 94 per cent. alcohol. The violet crystals of the required salt are separated mechanically from the wine-red crystals. The salt melts between 221° and 223° , it is easily soluble in water, and aq. alcohol. He also prepared **cobaltous dihydrazinotetrachloride**, $\text{CoCl}_2 \cdot 2\text{N}_2\text{H}_5\text{Cl} \cdot 2\frac{1}{2}\text{H}_2\text{O}$, in wine-red crystals melting at 213° to 215° with decomposition. Complex salts with **phenylhydrazine** were obtained by J. Moitessier, J. Ville and J. Moitessier, and W. Hieber and co-workers. W. Feldt prepared **cobaltous dihydroxylamino-chloride**, $\text{CoCl}_2 \cdot 2\text{NH}_2\text{OH}$, by adding hydroxylamine hydrochloride, and an alcoholic soln. of hydroxylamine to a boiling aq. soln. of cobalt chloride. The salt which separates out is washed with alcohol, and ether. It is rose-red; stable when protected from air; and detonates when heated. H. Rose observed that when cobalt chloride is heated with **phosphorus**, cobalt phosphide, and phosphorus trichloride are formed; the salt is easily decomposed by **phosphine**. O. J. Walker observed that in ammoniacal soln., a stick of phosphorus precipitates cobalt phosphide. H. L. Haken, R. Scholder and co-workers, and C. Paal and L. Friederici found that an **alkali hypophosphite** precipitates a mixture of cobalt and cobalt phosphide. F. Fleissner, and R. H. Pickard and J. Kenyon obtained compounds with the **phosphine oxides**—e.g., with **triphenyl phosphine oxide** there is formed $\text{CoCl}_2 \cdot 2(\text{C}_6\text{H}_5)_3\text{PO}$.

J. H. Weibel studied the action of **carbon monoxide**. S. von Laszczynsky studied the action of **benzene** on cobaltous chloride. W. J. Russell said that cobaltous chloride is insoluble in **carbon tetrachloride**; but it is readily dissolved by **ethyl chloride**. F. Schlegel, and A. Hantzsch and F. Schlegel obtained the complex $\text{CoCl}_2 \cdot 6\text{CH}_3\text{OH}$, by cooling conc. soln. of cobaltous chloride in **methyl alcohol** to -20° . The pale red crystals melt to a blue liquid at ordinary temp., and lose all their alcohol at 130° . E. Lloyd and co-workers found that the complex

$\text{CoCl}_2 \cdot 3\text{CH}_3\text{OH}$ separates from a soln. at 37° , and its vap. press. at 20° is 29.4 mm., and at 35° , 81.9 mm. The solubility of cobalt chloride in methyl alcohol, S grm. CoCl_2 per gram of solvent is :

S	20°	25°	30°	35°	37.1°	38°	40°	50°
	0.385	0.436	0.488	0.555	0.589	0.588	0.582	0.589
	$\text{CoCl}_2 \cdot 3\text{CH}_3\text{OH}$					$\text{CoCl}_2 \cdot 2\text{CH}_3\text{OH}$		

The transition temp. is 37.10 . The blue crystals of $\text{CoCl}_2 \cdot 2\text{CH}_3\text{OH}$ were obtained by A. Benrath by evaporating the soln. over sulphuric acid. E. Toporescu found that the blue soln. becomes red at 3° . M. R. Schmidt and H. C. Jones measured the viscosity of soln. of cobalt chloride in methyl alcohol, and in mixtures of methyl alcohol and glycerol; and R. Salvadori, and O. E. Frivold, the mol. lowering of the b.p. The colour and absorption spectrum were discussed by F. L. Cooper, H. A. Curtis and R. M. Burns, J. Groh and R. Schmidt, A. Hantzsch and co-workers, E. O. Hulbert and co-workers, H. C. Jones and co-workers, J. Lifschütz and E. Rosenbohm, C. Mazzetti, W. J. Russell, and E. Toporescu. According to F. Schlegel, solutions of cobalt halides in ethyl, amyl, and benzyl alcohols, glacial acetic acid, ethyl acetate, ethyl formate, acetone, acid amides, and nitriles are blue; and those in water, methyl alcohol, glycerol, glycol, and pyridine are rose-red. The electrical conductivity of the soln. was studied by H. C. Jones and L. McMaster, W. Hardt, H. R. Kreider and H. C. Jones, E. Rimbach and K. Weitzel, and M. R. Schmidt and H. C. Jones; the degree of ionization, by W. Hardt, H. R. Kreider and H. C. Jones, and R. Salvadori; and the magnetic properties by A. Quartaroli.

C. Winkler observed that anhydrous cobalt chloride is soluble in **ethyl alcohol**, and a sat. soln. in alcohol of sp. gr. 0.792 contains 23.66 per cent. of cobalt chloride, and has a sp. gr. of 1.0107. The soln. is blue by transmitted light, and black by reflected light. A 1 : 2500 soln. is distinctly blue, but a 1 : 10,000 soln. is colourless when cold, and blue when hot. Water added to the blue alcoholic soln. turns it violet and then red. Hence, the blue soln. can be used to detect the presence of water. E. Toporescu found that the blue soln. becomes red at -18° . The alcoholic soln. was also studied by E. Bödtker, and F. Bourion. S. von Laszczynsky found that 100 grms. of absolute alcohol can dissolve 56.2 grms. of cobalt chloride at room temp., and the addition of water precipitates hexahydrated cobalt chloride from the alcoholic soln. H. Ditz said that the blue soln. in 96 per cent. alcohol becomes red when it is mixed with water, and that the blue colour is restored by ether or absolute alcohol. R. Engel suggested that the blue soln. contains a blue alcoholate, and E. Bödtker assumed that the hexahydrate in alcoholic soln. decomposes into $\text{CoCl}_2 \cdot 5\text{H}_2\text{O} + \text{H}_2\text{O}$, and in dil. soln. the water is present as H_2O -mols., and in conc. soln. as $(\text{H}_2\text{O})_2$ -mols. E. Lloyd and co-workers found the solubility of cobalt chloride, S grm. of CoCl_2 per gram of ethyl alcohol, to be :

S	0°	10°	20°	30°	38°	40°	50°	60°	70°	80°
	0.450	0.486	0.544	0.626	—	0.674	0.651	0.668	0.729	0.703
	$\text{CoCl}_2 \cdot 3\text{C}_2\text{H}_5\text{OH}$					$\text{CoCl}_2 \cdot 2\text{C}_2\text{H}_5\text{OH}$				

The complex $\text{CoCl}_2 \cdot 3\text{C}_2\text{H}_5\text{OH}$ separates from the sat. soln. below the transition temp., 38° ; and the vap. press. of the blue crystals is 0.85 mm. at 10° , and 5.54 mm. at 30° . When the alcoholic soln. is evaporated in vacuo over phosphorus pentoxide, it deposits the complex $\text{CoCl}_2 \cdot 2\text{C}_2\text{H}_5\text{OH}$; the blue crystals are very deliquescent, and they lose all their alcohol at 100° . F. Bourion reported that the complex $\text{CoCl}_2 \cdot 2\frac{1}{2}\text{C}_2\text{H}_5\text{OH}$ separates in blue, deliquescent needles by evaporating an alcoholic soln. of cobalt chloride. The heat of formation is said to be 3.03 Cals., and the sp. gr. 1.32 at $22^\circ/4^\circ$. N. Schiloff and S. Pewsner studied the adsorption of the salt by charcoal from soln. of the salt in mixtures of alcohol and water. M. R. Schmidt and H. C. Jones studied the viscosity of soln. in ethyl alcohol, and in mixtures of ethyl alcohol and glycerol; O. E. Frivold, and A. Benrath, the mol. raising of the

b.p.; and M. S. Wrewsky, the sp. ht. The colour and absorption spectrum was discussed by W. R. Brode, A. R. Brown, F. L. Cooper, F. G. Donnan and H. Bassett, J. Formanek, J. H. Gladstone, A. Hantzsch, W. Hardt, R. A. Houstoun and co-workers, H. C. Jones and co-workers, C. Mazzetti, A. Rosenheim and V. J. Meyer, W. J. Russell, Y. Shibata and T. Inoue, J. H. Smith, H. W. Vogel, B. Völlmer, and M. S. Wrewsky; and the magnetic rotation of the plane of polarization, by R. W. Roberts. The electrical conductivity of the alcoholic soln. was studied by W. Hardt, H. C. Jones and co-workers, H. R. Kreider and H. C. Jones, E. Rimbach and K. Weitzel, A. Rosenheim and V. J. Meyer, and M. R. Schmidt and H. C. Jones; and the magnetic properties, by A. Chatillon, L. Landau, and A. Quartaroli.

The soln. of cobalt chloride in normal **propyl alcohol** is blue at ordinary temp. It was studied by E. O. Hulbert and co-workers, and E. Toporescu found that the soln. becomes red at -32° ; and in normal **butyl alcohol**, the blue soln. becomes red at -65° . E. O. Hulbert and co-workers studied the blue soln. of cobalt chloride in **iso-butyl alcohol**. W. Hardt measured the electrical conductivity of soln. in normal **amyl alcohol**, and A. Chatillon, the magnetic properties; E. Toporescu found that the blue soln. becomes red at -65° . The dark blue soln. of cobalt chloride in **iso-amyl alcohol** was studied by H. A. Curtis and R. M. Burns; the colour, and absorption spectrum, by E. O. Hulbert; the electrical conductivity, by R. E. Wilson; and the magnetic properties, by A. Quartaroli. H. A. Curtis and R. M. Burns observed that hydrogen sulphide only partially precipitates the cobalt from the soln. A. Hantzsch and F. Schlegel observed that the hot, blue soln. of the salt in **benzyl alcohol** deposits red crystals of the complex $\text{CoCl}_2 \cdot 4\text{C}_7\text{H}_7\text{OH}$. B. Köhnlein observed a slight reaction with **propyl iodide**.

F. W. O. de Coninck found that 100 grms. of a soln. in anhydrous **ethylene glycol** contain 10.6 of the hexahydrate at 16.4° . The soln. in glycol changes from purple to a bluish-violet when it is exposed to sunlight, and the purple soln. in glycol also becomes blue when heated. A. Hantzsch, and A. Grün and E. Boedecker prepared the blue complex $\text{CoCl}_2 \cdot 3\text{C}_2\text{H}_4(\text{OH})_2$, melting at 68° ; and A. Grün and E. Boedecker obtained the dihydrate and monohydrate, as well as the complex $\text{CoCl}_2 \cdot 2\text{C}_2\text{H}_4(\text{OH})_2$; it also forms a complex with **propylene glycol**, $\text{CoCl}_2 \cdot 3\text{C}_3\text{H}_6(\text{OH})_2$; and with **pinacone**, $2\text{CoCl}_2 \cdot 3\text{C}_6\text{H}_{12}(\text{OH})_2$. F. Guthrie observed that the soln. of cobaltous chloride in **glycerol** is carmine-red at ordinary temp., blue when heated, and yellowish when cooled by solid carbon dioxide. M. R. Schmidt and H. C. Jones, and H. C. Jones and J. S. Guy measured the viscosity, and the electrical conductivity of the soln.; and H. C. Jones and W. W. Strong, and W. J. Russell, the colour and absorption spectrum.

E. Bödtker observed that 100 grms. of **ether** dissolve 0.021 gm. of anhydrous cobalt chloride, and 0.291 gm. of the hexahydrate; and S. von Laszczynsky added that 100 grms. of ether dissolve 0.11 gm. of the dihydrate at 11° and 35° . F. N. Speller studied the partition of the chloride between ether and dil. hydrochloric acid. A. Hantzsch and H. Carlsohn, and W. J. Russell studied the colour and absorption spectrum of the soln. W. Eidman observed that cobaltous chloride is soluble in **acetone**. K. P. MacElroy and W. H. Krug observed that at 25° , 100 grms. of dry acetone dissolve 8.62 grms. of CoCl_2 ; A. Naumann and E. Vogt, at 18° , 2.78 grms.; S. von Laszczynsky, at 0° , 9.11 grms., and at 22.5° , 9.28 grms. of CoCl_2 , and 17.16 and 17.06 grms. of the dihydrate per 100 grms. of solvent, respectively, at 0° and 25° . W. R. G. Bell and co-workers found the solubility, S grms. CoCl_2 per 100 grms. of acetone, to be:

	0°	10°	20°	22.5°	25°	30°	40°	50°
S . . .	4.47	3.32	2.89	3.40	3.71	4.51	6.01	7.25

where below 19.5° , the solid phase is $\text{CoCl}_2 \cdot \text{C}_3\text{H}_6\text{O}$, and above that temp., CoCl_2 . A. Naumann and E. Vogt found that the blue soln. turns green when it has stood for some time. The complex was prepared by S. von Laszczynsky, who found that it is stable at 100° , but W. R. G. Bell observed that the vap. press. at 10° is 103.6 mm.,

and at 15°, 125 mm. A. Naumann and E. Vogt found that the sp. gr. of a sat. soln. is 0.825 at 18°/4°. A. L. Robinson measured the mol. raising of the b.p. The colour and absorption spectrum were studied by J. Groh and R. Schmidt, R. A. Houstoun and co-workers, and H. C. Jones and co-workers; the electrical conductivity, by F. Bauer, H. C. Jones and L. McMaster, E. Rimbach and K. Weitzel, and M. Wien; the electrolysis of the soln., by J. E. Marsh; and the magnetic properties, by A. Quartaroli. According to A. Naumann and E. Vogt, the soln. gives a precipitate of silver chloride when it is treated with silver nitrate; a dark blue soln. when it is treated with potassium thiocyanate; and when treated with ammonia, it first forms the diamminochloride and afterwards the hexamminochloride. They also observed the action of bromine, iodine, and hydrogen chloride on the soln. E. Raymond studied the complex formed with **benzaldehyde**.

O. Aschan found that 100 grms. of 95 per cent **formic acid** dissolve 6.2 grms. of CoCl_2 at 20.5°. A. W. Davidson found that the chloride is readily dissolved by **acetic acid**, and W. J. Russell added that the absorption spectrum resembles that of a dil. alcoholic soln. A. Naumann and J. Rill found that 100 grms. of **methyl acetate** dissolve 0.369 grm. of CoCl_2 at 18°, and the soln. has a sp. gr. of 0.938 at 18°/4°. The blue soln. becomes red when treated with water. They also observed the action of potassium thiocyanate, lithium nitrate, and of ammonia on the soln. A. Naumann and E. Alexander found that cobalt chloride is sparingly soluble in **ethyl acetate**, and S. von Laszczynsky, that 100 grms. of solvent dissolve 0.08 grm. of CoCl_2 at 14°, and 0.26 grm. at 79°, whilst the hexahydrate is insoluble in ethyl acetate. W. J. Russell found cobalt chloride is readily soluble in **amyl acetate**. S. Hakomori studied the action of **oxalic, citric, malic, and succinic acids** on cobalt chloride.

A. Naumann and A. Schier reported that 100 grms. of **acetonitrile**, at 18°, dissolve 4.08 grms. of CoCl_2 . The blue soln. becomes a little turbid by hydrogen sulphide, and this is not cleared up by the action of hydrogen chloride. They reported that a complex, $\text{CoCl}_2 \cdot 3\text{CH}_3\text{CN}$, is formed in the soln.; A. Hantzsch, however, said that the formula of the complex is $\text{CoCl}_2 \cdot 2\text{CH}_3\text{CN}$. A. Hantzsch and F. Schlegel, and A. Naumann found that cobalt chloride is easily soluble in **benzonitrile**, forming a deep blue soln., and when the hot sat. soln. is cooled, A. Werner obtained blue needles of a complex. K. A. Hofmann and G. Bugge, and A. Hantzsch observed that a complex is formed with **ethyl carbylamine**, $\text{CoCl}_2 \cdot 2\text{C}_2\text{H}_5\text{NC}$. P. Pfeiffer and F. Tappermann prepared compounds with **triphenyl- and tri-phenanthroline**. Cobalt chloride forms complex salts with many amines, and their stability was discussed by F. Mühlbauer. It forms a complex salt or salts with **methylamine**, studied by F. Ephraim and R. Linn, and W. Hieber and co-workers; with **ethylamine**, by F. Ephraim and R. Linn, W. Hieber and co-workers, and F. L. Shinn; with **allylamine**, by E. Lippmann and G. Vortmann, E. G. V. Percival and W. Wardlaw, A. Pieroni, and A. Pinotti—*vide supra*, cobaltic chloride; J. Frejka and L. Zahlova, with **diaminobutane**; with **ethyldiammine**, by W. Hieber and A. Woerner, and N. S. Kurnakoff; and with **hexamethylene-tetramine**, by J. C. Duff and E. J. Bills, G. A. Barbieri and F. Calzolari, M. R. Menz, and G. Scagliarini and G. Tartarini. The complex with **thiourea** was studied by G. Walter, and A. Rosenheim and V. J. Meyer. P. Walden found that red soln. are formed with **formamide**; and H. Röhrer studied the electrolysis of the soln. A complex is formed with **acetamide**, which was studied by G. André, G. Bruni and A. Manuelli, and L. F. Yntema and L. F. Audrieth; with **urethane**, by N. Castoro, J. Beato and M. de los D. Brugger, and G. Bruni and A. Manuelli; with **aniline**, by A. R. Leeds, W. Hieber and E. Levy, S. von Laszczynsky, W. Hieber and A. Woerner, G. Reddelein, and E. Lippmann and G. Vortmann; with **methylaniline**, by J. Reilly; with **butylaniline**, by J. Reilly; with **toluidine**, by E. Lippmann and G. Vortmann, J. Beato and M. de los D. Brugger, and G. Spacu; with **xylylidine**, by E. Lippmann and G. Vortmann; with **ethylenediamine**, by W. Hieber and F. Mühlbauer, and O. Stelling; with **o-phenylenediamine**, by

W. Hieber and K. Ries; with **diphenylethylenediamine**, by J. V. Dubsky and A. Langer; with **phenylenediamine**, by W. Hieber and co-workers, R. Cernatescu and co-workers, O. Stelling, and F. Feigl and M. Fürth; with **phenylbiguanidine**, by A. Smolka and A. Friedreich; with **benzidine**, by G. Spacu; with **diacetonitrile**, by F. Schlegel, and A. Naumann; with **diacetyloximes**, by J. Beato and M. de los D. Brugger, and K. Friedrich; with **camphidine**, by M. R. Menz; with **aldoximene**, by W. Hieber and co-workers; with **ketoxyms**, by W. Hieber and F. Leutert; with **dimethylglyoxime**, **diacetyldioxime**, and **methylthioacetyldioxime**, by F. Feigl and H. Rubinstein, K. Friedrich, F. Paneth and E. Thilo, E. Thilo, and J. V. Dubsky and F. Brychta; with **thiosemicarbazide**, by K. A. Jensen and E. R. Madsen; and J. V. Dubsky and A. Rabas obtained no complex with **glycine**; and G. Fuseya and K. Murata, none with **glycoll**. Compounds with **pyridine** were obtained by W. Biltz and co-workers, W. Hieber and E. Levy, W. R. Brode, A. Classen and B. Zahorsky, A. Hantzsch and co-workers, W. Hieber and A. Woerner, N. S. Kurnakoff, W. Lang, S. von Laszczynsky, A. T. Lincoln, J. N. Pearce, E. G. V. Percival and W. Wardlaw, F. Reitzenstein, I. Rohde and E. Vogt, F. Schlegel, G. Spacu and L. Caton, O. Stelling, R. Weinland and co-workers, and A. Werner and co-workers. J. N. Pearce and T. E. Moore gave for the percentage solubility:

S .	-48.2°	-50.3°	-30°	+15°	25°	70°	78.2°	90°	11.0°
	0	—	0.42	—	0.57	—	2.28	—	14.16
Solid phase	Py		CoCl ₂ .6Py		CoCl ₂ .4Py		CoCl ₂ .2Py		CoCl ₂

Complexes with **α -acetaminopyridine** were observed by F. L. Hahn and co-workers; with **piperidine**, by A. Werner and co-workers; with **dipyridyl**, by F. Blau; with **quinoline**, by E. Beckmann, E. G. V. Percival and W. Wardlaw, F. Borsbach, J. N. Pearce, W. R. Brode, and F. Reitzenstein; with **quinoline**, by E. G. V. Percival and W. Wardlaw; with **puridino-2, 3-thiophene**, by W. Steinkopf and G. Lützkendorf; with **phenanthroline**, by F. Blau; and with **thiocarbamide**, by A. Rosenheim and V. J. Meyer. N. V. Konduiroff and D. A. Fomin studied the action of cobalt chloride, on **organomagnesium compounds**. C. Dufraisse and D. Nakae studied the catalytic action of cobalt chloride on the oxidation of **acraldehyde**, **phenylformaldehyde**, **furfuraldehyde**, **styrene**, and **turpentine**; W. Thomson and F. Lewis, the action on **india-rubber**. E. G. Fuelnegg and G. Konopatsch studied the action of cobalt chloride as siccative or drier in various **oils**. J. E. Heck and M. G. Mellon studied rhythmic precipitations with **silicic acid**.

According to Z. Roussin, D. Vitali, D. Tommasi, A. Commaille, S. Kern, and K. Seubert and A. Schmidt, **magnesium** precipitates hydrated cobaltous oxide, mixed with a basic chloride, from neutral soln. of cobalt chloride, and at the same time some hydrogen is evolved; but feebly acidified soln. may be reduced. E. S. Hedges and J. E. Myers said that a magnesium-cobalt couple is produced when magnesium is dipped in a soln. of cobaltous chloride. According to Z. Roussin, and A. Commaille, neutral soln., hot or cold, give no precipitate with **zinc**, but if a third metal—lead or copper—is present, L. de Boisbaudron observed that the soln. may be reduced; and A. F. Gehlen, and J. L. Davies observed that an ammoniacal soln. may be reduced by zinc—*vide supra*, metallic precipitation of cobalt. M. Dombrow found that hydrated cobaltous chloride when heated with zinc, gives a violent reaction with the liberation of hydrogen. The precipitation of cobalt from soln. of the chloride in absolute alcohol by zinc, and **cadmium**, was studied by R. Müller and F. R. Thoïs. C. Formenti and M. Levi studied the reducing action of **aluminium**. H. Schulze found that, at a red-heat, **tungstic oxide** reacts with cobalt chloride in a current of carbon dioxide: $2\text{WO}_3 + \text{CoCl}_2 = \text{CoWO}_4 + \text{WO}_2\text{Cl}_2$. M. Curie and J. Saddy found cobalt chloride reduced the luminescence of **zinc sulphide**. D. Längauer studied the system: $\text{CoCl}_2 + \text{K}_2\text{SO}_4 \rightleftharpoons 2\text{KCl} + \text{CoSO}_4$. G. and P. Spacu obtained complex salts with **silver iodide**. E. Montignie observed that with **mercuric oxide**, cobaltous hydroxide, and with a small proportion of mercuric oxide, an oxychloride, $\text{CoCl}_2.3\text{CoO}.3\text{H}_2\text{O}$, is formed.

The double salts of cobaltous chloride.—The formation of solid soln. from soln. of chlorides and dihydrated cobalt chloride was discussed by A. Johnsen, O. Lehmann, and J. M. Merrick, and it is doubtful if a double salt is formed. The crystals of the solid soln. were examined by A. Neuhaus, J. W. Retgers, P. Gaubert, J. L. C. Schroeder van der Kolk, and B. Srehoff. H. W. Foote found that with soln., at 25°, containing the following percentage proportions of :

NH ₄ Cl	17.90	13.59	8.75	7.62	7.45
CoCl ₂	15.63	25.19	34.28	34.61	35.24
Solid phase	Solid soln. NH ₄ Cl. <i>n</i> CoCl ₂ .2H ₂ O			Solid soln. + CoCl ₂ .6H ₂ O	

There is the possibility that the solid phases contain isomorphous mixtures, or solid soln., of ammonium chloride and some double salt which is unstable when alone, for cases are known where two salts crystallize isomorphously to form a stable hydrate which neither salt yields when alone—*e.g.*, the monoclinic monohydrated copper and zinc sulphates. A. Benrath's results, at 25°, with the mol. proportions of the dissolved salt as abscissæ, and the number of mols. of water per mol. of dissolved salt as ordinates, are plotted in Fig. 90. F. W. J. Clendinnen, and A. C. D. Rivett and F. W. J. Clendinnen studied the ternary system : CoCl₂—NH₄Cl—H₂O, at 60°, in order to avoid complications with hydrates higher than CoCl₂.2H₂O. The results are summarized in Fig. 83. There is no indication of the formation of a double salt at this temp. There is a region of metastability bounded by dotted lines. The composition of the solid soln. can be represented by points on the line AD, which is continuous from ammonium chloride to dihydrated cobalt chloride.

FIG. 83.—The Ternary System : NH₄Cl—CoCl₂—H₂O at 60°.

O. Hautz reported hydrated **ammonium cobaltous trichloride**, NH₄Cl.CoCl₂.6H₂O, to be formed from soln. of cobalt and ammonium chlorides in equivalent proportions. G. Rosenheim and M. Platsch also prepared this salt. O. Hautz added that the crystals are always contaminated with those of ammonium chloride, and have to be purified by crystallization. The ruby-red, monoclinic crystals are deliquescent in moist air, and are freely soluble in water. F. Rose heated cobaltous hexamminochloride in air, and obtained what he regarded as **ammonium cobaltous amminotrichloride**, NH₄Cl.CoCl₂.NH₃, but W. Biltz said that the analysis agrees better with NH₄Cl.CoCl₂. $\frac{1}{2}$ NH₃. W. Biltz and B. Fetkenheuer could not prepare a definite compound by the method of F. Rose, but they obtained a product CoCl.(NH₄Cl)O₂.NH₃ by heating at 310° to 320° a mixture of cobaltous chloride and ammonium chloride in ammonia.

H. Franzen and H. L. Lucking obtained **hydrazine cobaltous tetrachloride**, CoCl₂(N₂H₄.HCl)₂.2H₂O. A. Ferratini prepared a **hydrazine cobaltous hydrazino-chloride**, 2N₂H₅Cl.CoCl₂. $\frac{1}{2}$ N₂H₄, from an aq. soln. of the components. The product was boiled in alcohol, and a mixture of wine-red, and violet crystals separated out. The violet crystals are separated mechanically. The salt furnishes prismatic needles which melt at 221° to 223°, and they are soluble in water, and in aq. alcohol.

Cobaltous chloride does not form a **potassium cobaltous chloride**. C. Mazzetti examined the system : KCl—CoCl₂—H₂O, at 20°, and observed no signs of a double salt. Expressing the composition of sat. soln. in percentages, he found :

CoCl ₂	33.52	33.15	31.58	28.37	20.25	7.40
KCl	4.73	6.81	6.79	7.70	11.56	19.37
Solid phases	CoCl ₂ .6H ₂ O + KCl			KCl		

The results are plotted in Fig. 86. A. Benrath's results at 25° are indicated in Fig. 89. H. W. Foote also observed no double salt is formed at 25°. The univariant point in the system is 8.24 per cent. KCl, and 32.91 per cent. CoCl_2 ; this is very close to the value obtained by C. Mazzetti at 20°. J. Kendall and K. P. Monroe, and N. A. Yajnik and R. L. Uberoy measured the sp. gr. and viscosity of mixed soln. of the two chlorides; and J. Trötsch, and G. Akerlöf and H. C. Thomas, the electrical conductivity. H. W. Foote obtained for the system: $\text{RbCl}-\text{CoCl}_2-\text{H}_2\text{O}$, at 25°:

CoCl_2	35.67	35.11	34.58	34.29	31.74	16.09	11.37	5.41	0
RbCl	0	5.98	6.83	7.79	9.34	30.52	38.03	43.58	48.57
Solid phases	$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$		$\text{RbCl} \cdot \text{CoCl}_2 \cdot 2\text{H}_2\text{O}$		$2\text{RbCl} \cdot \text{CoCl}_2 \cdot 2\text{H}_2\text{O}$			RbCl	

The results are plotted in Fig. 84. There are formed hydrated **rubidium cobaltous trichloride**, $\text{RbCl} \cdot (\text{CoCl}_2 \cdot 2\text{H}_2\text{O})$, and hydrated **rubidium cobaltous tetrachloride**,

FIG. 84.—The Ternary System : $\text{RbCl}-\text{CoCl}_2-\text{H}_2\text{O}$, at 25°.

FIG. 85.—The Ternary System : $\text{CsCl}-\text{CoCl}_2-\text{H}_2\text{O}$, at 25°.

$2\text{RbCl} \cdot \text{CoCl}_2 \cdot 2\text{H}_2\text{O}$. The univariant points are 6.09 per cent. RbCl and 35.02 per cent. CoCl_2 ; 7.68 per cent. RbCl and 34.36 per cent. CoCl_2 ; and 38.43 per cent. RbCl and 11.51 per cent. CoCl_2 . A. Benrath could not find the trichloride obtained by H. W. Foote, but obtained the tetrachloride. A. Benrath's results for the system: $\text{RbCl}-\text{CoCl}_2-\text{H}_2\text{O}$, at 25°, are plotted in Fig. 87, where, as before, the per-

FIG. 86.—The Ternary System : $\text{KCl}-\text{CoCl}_2-\text{H}_2\text{O}$, at 20°.

FIG. 87.—The Ternary System : $\text{RbCl}-\text{CoCl}_2-\text{H}_2\text{O}$, at 25°.

centage proportions of the two component salts, CoCl_2 , and RbCl , are plotted as abscissæ, and the number of mols. of water per mol. of mixed salt, as ordinates. A. Benrath's results for the ternary system: $\text{CsCl}-\text{CoCl}_2-\text{H}_2\text{O}$, at 25°, are plotted similarly in Fig. 85, and they agree with those obtained by H. W. Foote, where the compositions of the sat. soln. are expressed in percentages:

CoCl_2	35.67	35.73	32.58	31.09	22.57	8.98	7.75	0.25	0
CsCl	0	1.65	3.62	5.03	16.22	40.56	42.76	65.48	65.61
Solid phases	$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$		$\text{CsCl} \cdot \text{CoCl}_2 \cdot 2\text{H}_2\text{O}$		$2\text{CsCl} \cdot \text{CoCl}_2$		$3\text{CsCl} \cdot \text{CoCl}_2$		CsCl

The hexahydrate of cobalt chloride as solid phase has the invariant point 1.86 per cent. CsCl and 35.67 per cent. CoCl_2 , where the second phase is hydrated **caesium cobaltous trichloride**, $\text{CsCl} \cdot \text{CoCl}_2 \cdot 2\text{H}_2\text{O}$ —E. H. Ducloux reported crystals of the anhydrous salt—there is then another invariant point for 5.03 per cent. CsCl and 31.09 per cent. CoCl_2 , where the other solid phase is **caesium cobaltous tetrachloride**, $2\text{CsCl}_2 \cdot \text{CoCl}_2$; there is then an invariant point at 40.56 per cent. CsCl and 8.98 per cent. CoCl_2 , with the other solid phase **caesium cobaltous pentachloride**, $3\text{CsCl} \cdot \text{CoCl}_2$; and there is then the invariant point at 65.48 per cent. CsCl and 0.25 per cent. CoCl_2 , with caesium chloride as the other solid phase. O. Stelling and F. Olsson studied the X-ray absorption spectrum of $\text{CsCl} \cdot \text{CoCl}_2 \cdot 2\text{H}_2\text{O}$; E. H. Ducloux obtained crystals of $2\text{CsCl} \cdot \text{CoCl}_2$; and J. Vermande, crystals of $3\text{CsCl} \cdot \text{CoCl}_2$. These three caesium cobaltous salts were prepared by G. F. Campbell from mixed soln. of the component salts. Small plates of the trichloride were deposited from soln. in which the ratio Cs : Co varies from 0.4 : 1 to a syrupy soln. of cobaltous chloride; large plates or prisms of the tetrachloride, from soln. with Cs : Co ranging from 6 : 1 to 0.4 : 1; and combinations of cubic and octahedral crystals of the pentachloride, from soln. with Cs : Co ranging from 12 : 1 to 6 : 1. Each soln. was acidified with hydrochloric acid. G. and P. Spacu observed the formation of the **caesium cobalt amminotetrachlorides**, $\text{Cs}_2[\text{CoCl}_4] \cdot 9\text{NH}_3$ —the vap. press., at -82° , are :

Mols. NH_3 . .	12.66	11.00	10.74	9.97	9.74	9.18	8.92	8.86
p mm.	28.5	27.5	26.0	26.00	24.0	15.0	6.0	2.0

$\text{Cs}_2[\text{CoCl}_4] \cdot 5\text{NH}_3$ —with the vap. press. 6, 10.5, and 38.0 mm., respectively, at 0° , 16.9° , and 78° , and the heat of formation from the double salt, 14.20 Cals. per mol. of NH_3 ; $\text{Cs}_2[\text{CoCl}_4] \cdot 2\text{NH}_3$ —with the vap. press. 19 mm. at 78° , and the heat of formation, 16.97 Cals. per mol. of NH_3 ; and $\text{Cs}_2[\text{CoCl}_4] \cdot \text{NH}_3$ —with the vap. press. 19, 7, 3, 0.9 mm., respectively, for 1.34, 1.15, 1.12, and 1.09 mols. of NH_3 .

C. Mazzetti found that soln. of cobaltous and sodium chlorides, treated in a similar manner, at 20° , gave no evidence of the formation of a **sodium cobaltous chloride**. Expressing concentrations in percentages of the anhydrous salts, sat. soln. contain :

CoCl_2	34.98	33.38	33.05	32.84	21.45	8.20	0
NaCl	0	3.35	3.65	3.91	10.32	19.40	26.09
Solid phases	$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$				NaCl		

The results are plotted in Fig. 89. H. W. Foote obtained similar results at 25° ,

FIG. 88.—The Ternary System :
 $\text{CsCl} - \text{CoCl}_2 - \text{H}_2\text{O}$, at 25° .

FIG. 89.—The Ternary System :
 $\text{NaCl} - \text{CoCl}_2 - \text{H}_2\text{O}$, at 20° .

and he found the invariant point corresponds with 4.70 per cent. of sodium chloride and 32.91 per cent. of cobaltous chloride. A. Benrath found at 25° and 98° the mol.

percentages of NaCl to CoCl_2 in soln., and the number of mols. of water per mol. of mixed salt :

25°	NaCl	0	9.37	27.90	45.3	69.0	83.0	97.0	100 per cent.
	H_2O	6.67	6.15	5.49	7.56	8.32	8.48	8.58	8.33 mols.
98°	NaCl	0	15.7	25.2	34.2	57.7	65.4	86.6	100 per cent.
	H_2O	12.65	10.7	9.95	8.39	8.15	8.28	7.44	7.44 mols.

M. Löffler studied solid soln. with sodium chloride. C. Mazzetti, J. Kendall and K. P. Monroe, and N. A. Yajnik and R. L. Uberoy measured the viscosity of

FIG. 90.—The Ternary System :
 $\text{MCl-CoCl}_2\text{-H}_2\text{O}$, at 25°.

FIG. 91.—The Ternary System :
 $\text{LiCl-CoCl}_2\text{-H}_2\text{O}$.

mixed soln. of the two salts ; A. Benrath, the raising of the b.p. ; and C. Mazzetti, and J. Trötsch, the electrical conductivity. A. Chassevant reported hydrated **lithium cobaltous trichloride**, $\text{LiCl} \cdot \text{CoCl}_2 \cdot 3\text{H}_2\text{O}$, to be formed from soln. of the component salts, and he obtained the anhydrous salt by dehydration in a desiccator. The acicular crystals effloresce in a dry atmosphere and lose hydrogen chloride ; they are dissociated by water, but are stable in the presence of an excess of lithium chloride. The crystals are isomorphous with the corresponding salts of manganese, iron, and nickel. J. Kendall and K. P. Monroe, and N. A. Yajnik and R. L. Uberoy studied the sp. gr. and viscosity of the mixed soln. of the component salts ; and R. Engel, their colour. H. Bassett and H. H. Croucher formulate the compound : $[\text{Li}(\text{H}_2\text{O})_2][\text{Co}(\text{H}_2\text{O})\text{Cl}_3]$; A. Benrath examined the ternary system : $\text{LiCl-CoCl}_2\text{-H}_2\text{O}$, at 25°, and found for the percentage mol. proportions of lithium

FIG. 92.—Melting-point Curve of Lithium
and Cobaltous Chlorides.

FIG. 93.—Melting-point Curve of Calcium
and Cobaltous Chlorides.

chloride to cobalt chloride—abscissæ in Fig. 91—and the corresponding proportions of water mols. per mol. of mixture—ordinates in Fig. 85 :

LiCl ₂	0	32.1	64.57	64.80	75.40	77.8	93.68	96.25	100 per cent.
H ₂ O	12.6	12.2	6.96	7.14	5.31	5.46	5.48	5.51	5.71 mols.
Solid phases	CoCl ₂ ·6H ₂ O		CoCl ₂ ·2H ₂ O		4LiCl·CoCl ₂ ·10H ₂ O		LiCl·H ₂ O		

The results indicate the formation of hydrated **lithium cobaltous hexachloride**, 4LiCl·CoCl₂·10H₂O. H. Bassett and H. H. Croucher doubt the existence of this salt. J. W. Retgers observed that in the presence of conc. hydrochloric acid, lithium chloride separates from the mixed soln. A. Ferrari and A. Baroni showed that the m.p. curve of mixtures of cobalt and lithium chlorides, Fig. 92, has a maximum corresponding with the formation of **lithium cobaltous tetrachloride**, Li₂CoCl₄, m.p. 558°. H. Bassett and I. Sanderson examined the ternary system: LiCl-CoCl₂-H₂O at 0°, 25°, 40°, and 80°, and the results are summarized in Fig. 91. They observed **lithium cobaltous hexachloride**, 7LiCl·2CoCl₂·18H₂O; **lithium cobaltous heptachloride**, 3LiCl·2CoCl₂·6H₂O; and the dihydrate of the trichloride as well as of solid soln. between lithium cobaltous tetrachloride, 2LiCl·CoCl₂·2H₂O, and LiCl·H₂O.

A. Mailhe boiled a soln. of cobalt chloride with hydrated cupric oxide and obtained grey crystals of a **copper cobaltous trioxydichloride**, CoCl₂·3CuO·4H₂O.

A. Werner represented the salt by the formula: Cu₂(OH)₄·Cu(OH)₂·CoCl₂·H₂O. The green crystals are isomorphous with those of the corresponding nickel salt. W. A. Endriss made observations on this subject. R. Engel thought that a **calcium cobaltous chloride** was formed in a mixed soln. of the component chlorides. A. Ferrari and A. Inganni showed that the m.p. curve, Fig. 93, is of the simple V-type, with a eutectic at 614°, and 54.3 per cent. of CaCl₂. A. Benrath examined the ternary system: CaCl₂-CoCl₂-H₂O, at 25°, and found for the percentage mol. proportions of calcium chloride to cobalt chloride—abscissæ, Fig. 96—and the corresponding proportions of water mols. per mol. of mixture—ordinates in Fig. 96 :

FIG. 94. — Freezing - point Curves of the System: SrCl₂-CoCl₂.

CaCl ₂	0	30.78	45.6	67.7	78.2	84.9	94.8	100 per cent.
H ₂ O	12.63	11.48	10.94	9.62	8.58	6.54	7.18	7.21 mols.
Solid phases	CoCl ₂ ·6H ₂ O		CoCl ₂ ·6H ₂ O		CaCl ₂ ·6H ₂ O			

There is no sign of the formation of a double salt. H. C. Jones and W. W. Strong,

FIG. 95.—The Ternary System: LiCl-CoCl₂-H₂O, at 25°.

FIG. 96.—The Ternary System: MCl₂-CoCl₂-H₂O, at 25°.

and W. J. Russell studied the absorption spectrum of mixed soln. of the two salts; H. C. Jones and H. S. Uhler, the f.p. of the soln.; A. Benrath, the b.p.;

H. C. Jones and H. S. Uhler, the electrical conductivity; and F. G. Donnan and H. Bassett, the transport numbers, and constitution of the aq. soln. Similarly, A. Benrath obtained no sign of the formation of a **strontium cobaltous chloride** in his study of the ternary system: $\text{SrCl}_2\text{-CoCl}_2\text{-H}_2\text{O}$, at 25° , Fig. 96, when he found:

SrCl_2	.	.	.	0	17.92	27.15	41.01	78.5	100 per cent.
H_2O	.	.	.	12.65	11.40	10.68	13.01	15.05	15.85 mols.
Solid phases				$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$			$\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$		

A. Benrath obtained the curve, Fig. 96, for C. Mazzetti's data, for the system: $\text{BaCl}_2\text{-CoCl}_2\text{-H}_2\text{O}$, at 25° . A. Ferrari and A. Inganni observed no sign of a strontium cobaltous chloride on the f.p. curves of the system: $\text{SrCl}_2\text{-CoCl}_2$, Fig. 94. There is no miscibility in the solid state, and there is a eutectic at 564° , and 40.5 mols. per cent. of cobaltous chloride. C. Mazzetti examined the ternary system: $\text{BaCl}_2\text{-CoCl}_2\text{-H}_2\text{O}$, at 20° , and observed no sign of the formation of a **barium cobaltous chloride**. The percentage composition of the sat. soln. are:

CoCl_2	.	34.43	34.15	33.80	29.57	24.92	19.52	13.14	6.34
BaCl_2	.	0.45	0.37	0.38	0.88	2.01	5.48	10.03	16.50

The results of his study of the viscosity and electrical conductivity of mixed soln. of cobalt and barium chlorides were interpreted on the assumption that complex ions were formed.

FIG. 97.—The Ternary System : $\text{BaCl}_2\text{-CoCl}_2\text{-H}_2\text{O}$, at 20° .

FIG. 98.—The Ternary System : $\text{MgCl}_2\text{-CoCl}_2\text{-H}_2\text{O}$, at 20° .

H. Bassett and H. H. Croucher examined the ternary system: $\text{MgCl}_2\text{-CoCl}_2\text{-H}_2\text{O}$, at 25° . Expressing concentrations in percentages, they found for sat. soln.:

CoCl_2	.	35.87	28.78	12.08	12.43	10.00	8.95	8.44	4.44	0.00
MgCl_2	.	0.00	6.20	29.04	28.89	31.00	31.66	31.95	34.00	36.20
Solid phases		$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$			$\text{MgCl}_2 \cdot \text{CoCl}_2 \cdot 8\text{H}_2\text{O}$			$\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$		

The results are plotted in Fig. 98. There is clear evidence of the formation of a blue, hydrated **magnesium cobaltous tetrachloride**, $\text{MgCl}_2 \cdot \text{CoCl}_2 \cdot 8\text{H}_2\text{O}$. There was no evidence of the isomorphism of the hexahydrated magnesium and cobaltous chlorides. It is assumed, on the basis of the work of F. G. Donnan and H. Bassett, cited above, that the blue salt contains a complex cobalt anion, and they favour the hypothesis that the salt is constituted: $[\text{Mg}(\text{H}_4\text{O}_2)_4]^{++}[\text{CoCl}_4]^{--}$. The salt appears in deep blue rhombohedra, but small crystals have a reddish tinge in transmitted light. The results agree with observations by E. G. V. Percival and W. Wardlaw on complex salts of pyridine, quinoline, and quinaldine with the anion CoCl_4^{--} . A. Benrath's results for the system: $\text{MgCl}_2\text{-CoCl}_2\text{-H}_2\text{O}$, at 25° , are summarized in Fig. 96, the compound salt was not recognized. A. Ferrari and A. Inganni studied

the m.p. curve, and the results, summarized in Fig. 99, show no signs of a double salt at these temp. There is a continuous series of solid soln. J. Kendall and K. P. Monroe, A. Benrath, and N. A. Yajnik and R. L. Uberoy measured the sp. gr. and viscosity of the mixed soln.

A. Ferrari and A. Inganni obtained the curve, Fig. 101, for zinc and cobaltous chlorides. There is no sign of a zinc cobaltous chloride, there is no miscibility, and the eutectic temp. is the same as the m.p. of zinc chloride, namely 300° . H. Bassett and W. L. Bedwell also measured the f.p. of the mixtures, and found that the two curves descended from 735° , the f.p. of cobalt chloride, and 313° , the m.p. of zinc chloride, and met at the eutectic, which is between 311° and 313° , very near the m.p. of zinc chloride alone. The one curve corresponds with the separation of cobalt chloride in freezing, and the other curve corresponds with the separation of solid soln. of up to 7 per cent. of cobalt chloride in zinc chloride. The colour of the mixtures is like that of anhydrous cobalt chloride. They emphasized the fact that whilst the hydrated chlorides form definite compounds, the anhydrous chlorides do not do so; and this shows that it is unsafe to assume that a hydrated double or complex salt will remain a chemical individual after dehydration.

FIG. 99.—The Fusion Curve of the System : $\text{MgCl}_2\text{--CoCl}_2$.

FIG. 100.—Ternary Systems : $\text{MCl}_2\text{--CoCl}_2\text{--H}_2\text{O}$, at 25° .

FIG. 101.—Freezing-point Curves of the System : $\text{ZnCl}_2\text{--CoCl}_2$.

A. Benrath's observations on the ternary system : $\text{ZnCl}_2\text{--CoCl}_2\text{--H}_2\text{O}$, at 25° , are summarized in Fig. 100. The first portion of the curve has the hexahydrate, $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$, as solid phase, and the last portion has hydrated zinc chloride as solid phase. In between there is a curve supposed to represent the compound hydrated zinc cobalt hexachloride, $2\text{ZnCl}_2 \cdot \text{CoCl}_2 \cdot 12\text{H}_2\text{O}$, analogous to $\text{CdCl}_2 \cdot \text{CoCl}_2 \cdot 12\text{H}_2\text{O}$, obtained in the soln. with cadmium and cobalt chlorides. This was not confirmed by H. Bassett and H. H. Croucher. These investigators found that the equilibrium conditions are not so simple as those indicated in Fig. 100, because of the complications introduced by the hydrolysis of the zinc chloride and by the formation of solid soln. The following is a selection from an extensive series of readings, where the concentrations of sat. soln. are expressed in percentages, and the Greek letters refer to solid soln. :

CoCl_2	35.87	31.20	29.48	13.51	12.61	17.23	4.19	0.61	—	2.60
ZnCl_2	0	27.91	33.31	60.09	63.40	57.95	77.38	80.02	81.28	78.58
	$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$		$\text{CoCl}_2 \cdot 2\text{H}_2\text{O}$	α	β	γ	δ	ϵ	$\text{ZnCl}_2 \cdot 1\frac{1}{2}\text{H}_2\text{O}$	

The results are summarized in Fig. 102. The isotherm of the system consists of eight well-marked portions. The soln. richest in cobalt chloride are in equilibrium with the hexahydrate. Addition of zinc chloride causes, first, a fall in the amount of cobalt chloride present in the soln. (reckoned as a percentage of the total weight of soln.), followed by a slight rise until, when the soln. contains 31.20 per cent. of cobalt chloride and 27.91 per cent. of zinc chloride, the dihydrate, $\text{CoCl}_2 \cdot 2\text{H}_2\text{O}$, becomes the stable solid phase. Its range of existence is comparatively short,

and at 29.48 per cent. CoCl_2 and 33.31 per cent. ZnCl_2 , hydrated **zinc cobaltous tetrachloride**, $\text{CoCl}_2 \cdot \text{ZnCl}_2 \cdot 6\text{H}_2\text{O}$, appears. From this point to 13.60 per cent. CoCl_2 and 60.09 per cent. ZnCl_2 , there is a solid phase consisting of a series of solid soln.— *α -solid solutions*—of $\text{ZnCl}_2 \cdot 3\text{H}_2\text{O}$ in $\text{ZnCl}_2 \cdot \text{CoCl}_2 \cdot 6\text{H}_2\text{O}$, that is, between $[\text{Zn}(\text{OH})_6]^{+}[\text{ZnCl}_4]^{-}$ and $[\text{Co}(\text{H}_2\text{O})_6]^{+}[\text{ZnCl}_4]^{-}$. These soln. crystallize

FIG. 102.—The Ternary System : ZnCl_2 — CoCl_2 — H_2O , at 25° .

$[\text{Zn}_2\text{Cl}_6]_2$. The γ -solid soln. crystallize in long prisms with oblique ends. The γ -solid soln. is in turn replaced by a fourth series— *ϵ -solid solutions*—as the concentration attains 0.61 per cent. CoCl_2 and 80.02 per cent. ZnCl_2 . The constituent of the ϵ -solid soln. is $\text{ZnCl}_2 \cdot 1\frac{1}{3}\text{H}_2\text{O}$, that is, $[\text{Zn}(\text{H}_2\text{O})_4]^{+}[\text{Zn}_2\text{Cl}_6]^{-}$, and the other constituent is $[\text{Co}(\text{H}_2\text{O})_4]^{+}[\text{Zn}_2\text{Cl}_6]^{-}$. The ϵ -solid soln. furnish clear, 6-sided plates associated, maybe, with pseudomorphs of the δ -solid soln. The solubility curves of the γ - and ϵ -solid soln. can be followed some distance into the metastable region. There is yet a fifth series of solid soln.— *δ -solid solutions*—in which $\text{ZnCl}_2 \cdot 1\frac{1}{3}\text{H}_2\text{O}$, $[\text{Zn}_2(\text{H}_2\text{O})_6]^{+}[\text{ZnCl}_4]_2^{-}$ is one constituent, and the other constituent is $[\text{Co}(\text{H}_2\text{O})_6]^{+}[\text{ZnCl}_4]_2^{-}$. The series of δ -solid soln. is metastable over its whole, moderately extensive range; and it furnishes small, diamond-shaped plates, and rhombs rather like those of calcite. Lastly, anhydrous zinc chloride may be obtained at 25° in metastable equilibrium with a limited range of soln. of zinc and cobalt chlorides. F. G. Donnan and H. Bassett studied the colour and constitution of the aq. soln.

C. van Hauer reported **cadmium cobaltous hexachloride**, $2\text{CdCl}_2 \cdot \text{CoCl}_2 \cdot 12\text{H}_2\text{O}$, or, according to G. Spacu and L. Caton, $[\text{CdCl}_6][\text{Cd}(\text{H}_2\text{O})_6][\text{Co}(\text{H}_2\text{O})_6]$, to be deposited from a soln. of 3 mols. of the cobalt salt to 4 mols. of the cadmium salt allowed to evaporate spontaneously in not too warm a place. A. Benrath studied the ternary system: CdCl_2 — CoCl_2 — H_2O , at 25° , and obtained a curve with the hydrated component salts as solid phases at each end, and this double salt in between, Fig. 99, where the mol. proportions of the two salts are expressed in percentages, are the abscissæ, and the number of mols. of water per mol. of the mixed salt are the ordinates. The data were:

CdCl_2	0	5.14	21.85	40.3	41.1	43.7	57.8	70.4	80.3	100
H_2O	12.66	11.92	9.37	6.38	6.25	6.44	6.86	6.37	6.93	7.94
		$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$			$2\text{CdCl}_2 \cdot \text{CoCl}_2 \cdot 10\text{H}_2\text{O}$			$(\text{CdCl}_2 \cdot 2\frac{1}{3}\text{H}_2\text{O})$		

The crystals of the complex salt are columnar, and the same in colour as those of hydrated cobalt chloride, and they resemble those of the magnesium and manganese complex salts. J. Grailich said that the rhombic crystals have the axial ratios $a : b : c = 1.0958 : 1 : 0.3847$, and that the (100)-cleavage is imperfect. The crystals were also examined by J. Grailich and V. von Lang. A. Ferrari and A. Inganni found the f.p. curves, Fig. 103, show a continuous series of solid soln. H. Bassett

and I. Sanderson also noted the formation of solid soln. C. von Hauer observed that the crystals deliquesce in moist air, but are stable in dry air; they effloresce over sulphuric acid or calcium chloride. They can be dried, without decomposition, in vacuo; they lose 10 mols. of water at 100° ; and at a higher temp., the salt melts in its water of crystallization, it then becomes dark blue, and solid. The solid melts at a red-heat and sublimes with partial decomposition. G. Spacu and L. Caton prepared a complex salt with pyridine, namely, **cadmium cobaltous octopyridinohexachloride**, $2\text{CdCl}_2 \cdot \text{CoCl}_2 \cdot 8\text{C}_5\text{H}_5\text{N}$.

P. A. von Bonsdorff reported **mercuric cobaltous tetrachloride**, $\text{HgCl}_2 \cdot \text{CoCl}_2 \cdot 4\text{H}_2\text{O}$, or, according to H. Bassett and H. H. Croucher, $[\text{Co}(\text{H}_2\text{O})_4]\text{HgCl}_4$, to be formed by evaporating a mixed soln. of the component salts. The carmine-red, columnar crystals are isomorphous with the magnesium and iron mercuric salts. R. Varet gave 1.08 Cals. for the heat evolved in mixing soln. of CoCl_2 and 2HgCl_2 , at 17° , and 0.90 Cal. for soln. of CoCl_2 and HgCl_2 , at 18° . A. Hantzsch observed that an alcoholic soln. of cobalt chloride becomes red when treated with mercuric chloride, owing to the formation of a complex salt. A. Benrath studied the ternary system: HgCl_2 - CoCl_2 - H_2O , at 25° , but did not find this complex salt; his data are summarized in Fig. 100. Expressing the concentrations of sat. soln. at 25° , percentages, H. Bassett and H. H. Croucher found:

CoCl_2	35.87	30.69	21.54	20.96	18.02	15.14	4.33	0
HgCl_2	0	15.14	51.00	51.76	57.81	56.54	21.56	6.90
	$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$		$\text{HgCl}_2 \cdot \text{CoCl}_2 \cdot 4\text{H}_2\text{O}$			HgCl_2		

The results are plotted in Fig. 104. H. Bassett and H. H. Croucher added that the effect of cobalt chloride in increasing the solubility of mercuric chloride is remarkable and strikingly shows the great tendency of the latter compound to form negative complex ions. The solubility curve of the mercuric chloride is concave to the water-apex of the triangle. This is unusual, for in 3-component systems containing water and two electrolytes, the solubility curves are nearly always convex to this point. This convexity is due to the opposition of two effects, one causing a diminution of solubility, and the other an increase. In the present instance, since mercuric chloride is very slightly ionized, the depressing effect of the chlorine ions from the cobalt chloride is very slight, but their effect in producing HgCl_4^{--} complexes is very great. From the first additions of cobalt chloride there is, therefore, an increase in solubility of the mercuric chloride, but the proportionate effect diminishes with increasing additions, and so a concave curve results. F. G. Donnan and H. Bassett, A. Hantzsch and co-workers, and Y. Shibata and co-workers studied the constitution of the soln.

A. Mailhe reported two basic salts obtained by allowing mercuric oxide to stand in contact with soln. of cobalt chloride—**mercuric trioxydichloride**, $3\text{CoO} \cdot \text{HgCl}_2 \cdot \frac{1}{2}\text{H}_2\text{O}$, as a green powder consisting of 4-sided plates; and **mercuric**

FIG. 104.—The Ternary System: HgCl_2 - CoCl_2 - H_2O .

hexoxytetrachloride, $6\text{CoO} \cdot \text{CoCl}_2 \cdot \text{HgCl}_2 \cdot 20\text{H}_2\text{O}$, in crystalline granules. G. Spacu and L. Caton reported a complex salt with aniline; F. Calzolari and U. Tagliavini, one with hexamethylenetetramine; and G. Spacu, one with benzidine.

J. Gewecke prepared hydrated **thallic cobaltous octochloride**, $2\text{TiCl}_3 \cdot \text{CoCl}_2 \cdot 8\text{H}_2\text{O}$, in hygroscopic, red crystals, by allowing a soln. of the component salts in water, acidified with hydrochloric acid, to evaporate in vacuo over sulphuric acid. S. M. Jørgensen obtained hydrated **cobaltous stannic hexachloride**, $\text{CoSnCl}_6 \cdot 6\text{H}_2\text{O}$, by slowly cooling a hot, aq. soln. of equimolar parts of the component salts. J. G. F. Druce oxidized with chlorine a soln. of 7.1 grms. hexahydrated cobalt chloride, and 6.7 grms. of stannous chloride in dil. hydrochloric acid, and then concentrated and cooled the soln. for rose-red crystals. According to S. M. Jørgensen, the rhombohedral crystals have the axial ratio $a : c = 1 : 0.5103$, and $\alpha = 112^\circ 20'$; the (101)-cleavage is perfect—*vide* the nickel salt. The crystals deliquesce in moist air; and effloresce in dry air; at 100° , they lose water and stannic chloride. The crystals were examined by H. Töpsøe and C. Christiansen; their sp. gr. is 2.684; S. M. Jørgensen gave 2.298. E. von Biron studied the effect of cobalt chloride on the hydrolysis of stannic chloride in aq. soln. A. Benrath studied the raising of the b.p. of aq. soln. A. Ferrari and C. Colla studied the f.p. of the system: $\text{SnCl}_2\text{--CoCl}_2$, Fig. 105, and of the system with lead-cobalt chloride, Fig. 106. In the

FIG. 105.—The System: $\text{SnCl}_2\text{--CoCl}_2$.

FIG. 106.—The System: $\text{PbCl}_2\text{--CoCl}_2$.

former case, there is a eutectic at about 240° , with about 4 mols. per cent. of CoCl_2 , and in the latter case, at 424° , and 23.5 mols. per cent. of CoCl_2 .

A. Ferrari and A. Inganni found that the f.p. curve of mixtures of manganese and cobalt chlorides gave no evidence of the formation of a **manganese cobaltous chloride**. There is formed a continuous series of solid soln., Fig. 107. W. Storten-

FIG. 107.—Freezing-point Curves of the System: $\text{CoCl}_2\text{--MnCl}_2$.

FIG. 108.—Solid Solutions of Manganese and Cobaltous Chlorides.

beker observed that aq. soln. of the two chlorides, containing a mol. of cobalt chloride and 0 to 5 mols. of manganese chlorides, furnish red crystals of the solid

soln. isomorphous with hexahydrated cobaltous chloride. If the soln. contains more than 2 mols. of the manganese chloride, the violet crystals of the solid soln. form spontaneously, and are isomorphous with tetrahydrated manganese chloride. The results with soln. of various concentrations are summarized in Fig. 108.

A. Ferrari and co-workers obtained the f.p. curves of ferrous and cobaltous chlorides, and found no evidence of a **ferrous cobaltous chloride**. A continuous series of solid soln. is formed, Fig. 109. This also agrees with the data from the

FIG. 109.—Freezing-point Curves of the System: $\text{FeCl}_2\text{--CoCl}_2$.

FIG. 110.—The Ternary System: $\text{FeCl}_3\text{--CoCl}_2\text{--H}_2\text{O}$, at 25° .

X-radiograms where the lattice parameter a is 7.05 Å. for cobaltous chloride; 7.075 Å. for 8CoCl_2 and 2FeCl_2 ; 7.095 Å. for 6CoCl_2 and 4FeCl_2 ; 7.115 Å. for 4CoCl_2 and 6FeCl_2 ; 7.135 Å. for 2CoCl_2 and 8FeCl_2 ; and 7.155 Å. for FeCl_2 . Y. Osaka and T. Yaginuma studied the system: $\text{FeCl}_3\text{--CoCl}_2\text{--H}_2\text{O}$, at 25° , and observed no evidence of the formation of a **ferric cobaltous chloride**. Expressing the composition of the sat. soln. in percentages, they found the results indicated in Fig. 110, and:

FeCl_3	.	.	.	0	7.7	41.07	43.28	43.95	47.17	49.42
CoCl_2	.	.	.	30	29.36	7.99	7.40	6.58	2.47	0
Solid phases				$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$				$\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$

§ 16. Cobaltic Chloride and its Complex Salts

In 1835, G. C. Winkelblech¹ observed that cobaltous chloride cannot be converted into **cobaltic chloride**, CoCl_3 , by treating it with an excess of chlorine, but when freshly-prepared cobaltic hydroxide is treated with cold hydrochloric acid, the soln. contains some cobaltic chloride. The salt has not yet been isolated. W. Glud and co-workers discussed the preparation of oxygen by a process based on this reaction. In confirmation of the earlier observation, R. J. Meyer and H. Best showed that if alcoholic hydrogen chloride is employed in place of hydrochloric acid, a dark green soln. is produced which soon turns rose-red—presumably the dark green soln. contains cobaltic chloride which soon changes to rose-colour of ordinary cobaltous chloride. C. Schall and H. Markgraf passed chlorine into a soln. of cobaltous chloride in alcohol, or conc. hydrochloric acid at -60° ; and possibly a tetrachloride is formed at -75° . C. Schall obtained evidence of the formation of cobaltic chloride in the anodic oxidation of a HCl-alcoholic soln. of cobaltous chloride.

The CoA_6 or Hexammine Family.

In 1851, F. A. Genth first prepared *cobaltic luteochloride*, or **cobaltic hexammino-chloride**, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$, by oxidizing an ammoniacal soln. of a cobaltous salt by exposure to air, and it was afterwards prepared by E. Frémy, O. W. Gibbs and F. A. Genth, and C. D. Braun. E. J. Mills oxidized the soln. with potassium permanganate; A. Carnot, with hydrogen dioxide; G. T. Morgan and J. D. M. Smith, with hydrogen dioxide in an autoclave; C. D. Braun, with lead dioxide; L. Jacobsen, with chlorine; sodium hypochlorite, or bleaching powder; H. and W. Biltz, with iodine; and S. M. Jørgensen, with a nitrate and hydrochloric acid. H. and W. Biltz treated a conc. soln. of cobalt chloride (100 grms.) and ammonium chloride (30 grms.) with a soln. of silver chloride in 20 per cent. aq. ammonia for 24 hrs. at 40° , or 2 days at ordinary temp. The precipitate was extracted with water at 25° ; and the filtrate and washings at 80° were treated with conc. hydrochloric acid to precipitate the silver, and cooled. The product can be re-crystallized from water. The hexammine was also prepared by S. M. Jørgensen, H. and W. Biltz, W. D. Harkins and co-workers, G. T. Morgan and J. D. M. Smith, A. B. Lamb and A. T. Larson, A. Duboscq, and A. Werner and H. Müller, by treating pentammino-salts with hydrochloric acid, or chlorine. P. Pfeiffer discussed the structure of the compounds.

The hexammine occurs in wine-red, or brownish orange-red, dichroic crystals, which J. D. Dana considered to be rhombic, but which were shown by C. Klein, and F. M. Jäger to belong to the monoclinic system, and to have the axial ratios $a:b:c=0.9880:1:0.6501$, and $\beta=91^\circ 19''$. The needle-like crystals may have rhombic symmetry; no cleavage has been noticed. C. Klein observed twinning about the (001)-plane. H. Lessheim and co-workers, and G. Böttker-Naess and O. Hassel studied the lattice structure. F. M. Jäger gave for the topic axial ratios, $\chi:\psi:\omega=6.179:6.254:4.006$; and 1.704 for the sp. gr. at 15° ; J. D. Dana gave 1.7016 for the sp. gr. at 20° ; W. Biltz and E. Birk, sp. gr. 1.710 at $25^\circ/4$, and mol. vol. 156.4; F. Ephraim and O. Schütz, sp. gr. 1.707 at $25^\circ/4$, and mol. vol. 156.7; G. L. Clark and co-workers, sp. gr. 1.744 at 25° , and mol. vol. 153.37;

and R. Lorenz and I. Posen, and I. Posen, sp. gr. 1.7098 (reduced to a vacuum), and mol. vol., computed for absolute zero, 152.0. W. Biltz and co-workers estimate that the mol. vol. of the ammonia is smaller in cobaltic salts than it is in the cobaltous salts; the mol. vol. of the ammonia in the hexamminochloride is 17; and, according to G. L. Clark and co-workers, 16.09 in comparison with 20 for the cobaltous hexamminochloride. The subject was discussed by R. Klement, E. Birk, and W. Biltz. G. Beck gave 323 Cals. for the heat of formation.

H. Skraup and co-workers, and M. Kidokoro measured the capillary properties of aq. soln. J. Peterson, W. D. Harkins and co-workers, and A. Werner and

FIG. 111.—The Thermal Dissociation of Cobaltic Hexamminochloride.

C. Herty studied the lowering of the freezing-point of aq. soln., and the results agree with the assumption that the salt is tetra-ionic. E. N. Gapon studied the diffusion of the salt in soln. According to W. Biltz, and G. L. Clark and co-workers, when the dry salt is heated to 215°, it passes into chloropentamminochloride, and with further heating, the results are indicated in Fig. 111, but above 250° it is reduced to cobaltous

chloride; and when heated to constant weight in vacuo at 180°, the residue contains 2 mols. of the chloropentamminochloride, for 3 mols. of $\text{NH}_4\text{Cl} \cdot \text{CoCl}_2 \cdot \frac{1}{2}\text{NH}_3$.

The absorption spectrum was measured by W. F. Beyer, A. Gordienko, M. Chatalet-Lavollay, J. Kranig, R. Luther and A. N. Nikolopoulos, R. Samuel and co-workers, J. Angerstein, A. N. Nikolopoulos, C. Schleicher, Y. Shibata, and Y. Shibata and G. Urbain; the X-ray spectrum, by O. Stelling, and S. Aoyama and co-workers; and the Raman effect, by D. M. Bose and S. Datta, and I. Damaschun. R. Lorenz and I. Posen, and I. Posen gave for the equivalent electrical conductivity, λ , of a mol of the salt in v litres of water, at 25°:

v	32	64	128	256	512	1024
λ	124.6	135.9	147.9	155.7	163.9	169.9

and $\lambda_\infty = 169.5$ mhos. W. D. Harkins and co-workers gave for soln. with C equivalents of the salt per litre at 0° and 25°:

C	0.1107	0.07722	0.05293	0.02015	0.002032	0.0004315
λ { 0°	56.09	58.90	63.27	69.8	85.7	91.0
25°	101.3	109.2	117.2	130.2	160.0	172.0

Observations on the conductivity of the soln. were also made by G. R. Mines, A. Werner and A. Miolati, H. Ley, and J. Petersen. The results agree with the data on the lowering of the f.p. of the aq. soln. in that the ionization of the salt furnishes 4 ions per mol.: $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \rightleftharpoons [\text{Co}(\text{NH}_3)_2]^{+++} + 3\text{Cl}^-$. The subject was discussed by A. Werner and C. Herty, and W. D. Harkins and co-workers. E. N. Gapon, R. Lorenz and I. Posen, and I. Posen found the transport number of the anion, at a dilution $v=90$ per gram-equivalent, to be 0.430, 0.620, and 0.810, respectively, for 1, 2, or 3 chlorine atoms per mol.; and they gave for the mobility of the $[\text{Co}(\text{NH}_3)_6]^{+++}$ -ion, 27.1 to 46.8. A. Bethe and T. Toropoff studied the electro-osmosis of the salt in soln.; and H. Freundlich and G. Ettisch, the electrokinetic potential at glass surfaces. A. B. Lamb and A. T. Larson measured the oxidation potentials of 6 cobaltic amines in soln. of ammonium hydroxide, and calculated the concentration of the Co^{+++} -ion in the mol. normal soln. of ammine. The oxidation potential of the hexamminochloride in 0.077M-NH₄OH is 0.1558 volt. The order of stability, increasing onwards, is 1,6-dinitrotetrammine, hexammine, nitropentammine, 1,2-dinitropentammine, and aquopentammine. A. B. Lamb and A. T. Larson's value for the equilibrium constant in $[\text{Co}(\text{NH}_3)_6]^{+++} \rightleftharpoons [\text{Co}^{+++}] + 6[\text{NH}_3]$, is 2.2×10^{-34} . N. R. Dhar and G. Urbain found that the polarization tension of $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$ decreases as the NH_3 -mols. are replaced by

H₂O-mols., whereas in the series [Co(NH₃)₄Cl₂]Cl, the contrary holds good. The replacement of a molecule of water by a halogen in such a compound as Co(NH₃)₅H₂OCl₃ causes a rise in the polarization tension. Further, in the purpureo-salts, the tension is higher when the purpureo-complex contains a more negative radicle. The replacement of a chlorine atom by a nitro-group, or of two chlorine atoms by a carbonato-group, causes a lowering of the polarization tension. The marked rise in the tension following on the substitution of an hydroxy-group for a chlorine atom is in agreement with the fact that these complex compounds are only stable in alkaline media. A. L. T. Moesveld and H. J. Hardon studied the electrostriction of the compound. E. Feytis gave for the magnetic susceptibility -0.38×10^{-6} mass unit; and P. Pascal, -0.376×10^{-6} mass unit. Observations on the magnetic properties were made by P. Collet, P. Weiss, E. Rosenbohm, D. M. Bose, L. C. Jackson, W. Biltz, and S. Berkman and H. Zocher. The co-ordination and structure were discussed by P. C. Ray; magnetic anisotropy, by L. W. Strock; the piezoelectric phenomena, by A. Hettich; and the electrostatic explanation of complex salt formation, by A. E. van Arkel and J. H. de Boer.

H. Lessheim and co-workers, F. Ephraim and W. Flügel, and F. Ephraim studied the bonding of the anions in salts of this type; J. A. V. Butler, T. M. Lowry, and C. H. Spiers, the electronic structure; and W. Biltz, A. B. Lamb and A. T. Larson, G. L. Clark and co-workers, J. A. N. Friend, and E. E. Turner, the constitution. P. Job examined the fractional precipitation of the three chlorides by soln. of silver nitrate. P. Mosimann and F. Ephraim gave 0.20 mol or 11.8 grms. per litre for the solubility of the salt in water; and observations were made by J. N. Bronsted and J. W. Williams. S. M. Jörgensen observed that the hexammine is very slowly hydrolyzed by boiling water; and R. Schwarz and co-workers observed that hydrolysis occurs at ordinary temp. in ultra-violet light. A. Benrath, and H. Pitzler studied the solubility of the salt in hydrochloric acid and water. E. Böhm observed that when a soln. of the hexamminochloride is treated with dil. hydrofluoric acid, brownish-yellow, prismatic crystals of **cobaltic hexamminofluodichloride**, [Co(NH₃)₆]FCl₂, are formed; the crystals effloresce in air or in vacuo; and they are freely soluble in hot water, but sparingly soluble in cold water and dil. acids. S. M. Jörgensen observed that with cold, sat. soln. of the ammine, the salt is precipitated by the addition of acids—dil. nitric acid, or conc. hydrochloric or hydrobromic acids; dil. sulphuric acid precipitates a sulphate; crystalline precipitates are produced by the addition of ammonium oxalate, sodium pyrophosphate, gold trichloride, and by potassium iodide, chromate, dichromate, ferrocyanide, ferricyanide, cobaltocyanide, and chromocyanide; iodine and potassium iodide give a black precipitate; ammoniacal sodium hydrophosphate gives a precipitate; mercuric chloride gives a precipitate only after hydrochloric acid has been added; and hydrochloroplatinic acid and sulphuric acid precipitate a double salt. F. Ephraim observed that when the well-cooled hexamminochloride is treated with ammonia gas or with liquid ammonia, cooled with solid carbon dioxide, **cobaltic dodecamminochloride**, [Co(NH₃)₆]Cl₃.6NH₃, is formed. At -24° , it loses 3NH₃ to form **cobaltic enneamminochloride**, [Co(NH₃)₆]Cl₃.3NH₃; between -12° and -6° , it forms a series of solid soln. with **cobaltic octamminochloride**, [Co(NH₃)₆]Cl₂.2NH₃; at -6° , it passes into **cobaltic heptamminochloride**, [Co(NH₃)₆]Cl₃.NH₃; and at 24.5° to 30° , it forms the hexammine. K. Matsuno, and H. Freundlich and H. Schucht studied the flocculation of arsenic sulphide sol by the hexammine; N. Schiloff and B. Nekrassoff, the reduction of the ammine, and the adsorption of soln. of the salt by activated charcoal; R. Schwarz and W. Krönig, the change of the hexammine to the chloropentammine by shaking the aq. soln. with charcoal, or silica-gel; F. Ephraim found that a 5 per cent. aq. soln. gives a precipitate with many substituted benzene and naphthalene substituted sulphonc acids.

For example, with 5-nitro-, 6-nitro-, and 7-nitro-naphthalene- α -sulphonic acids, 2 : 6-dinitro-*m*-xylene-4-sulphonic acid, 2 : 6-dinitrotoluene-4-sulphonic acid, 4 : 5-dichloro-2-nitrobenzenesulphonic acid, 2 : 5-dichlorobenzenesulphonic acid, 5-chloronaphthalene- α -sulphonic acid, 3 : 4-dichlorobenzenesulphonic acid, 4-chloro-2-nitrobenzenesulphonic acid, 2-chloro-3 : 5-dinitrobenzenesulphonic acid, *m*-nitrotoluene-4-sulphonic acid, *p*-nitrotoluene-2-sulphonic acid, dibromonaphthalene- β -sulphonic acid, 1-nitronaphthalene-3 : 7-disulphonic acid, 1-nitronaphthalene-3 : 6-disulphonic acid, β -bromonaphthalenedisulphonic acid, naphthalene-1 : 6-disulphonic acid, naphthalene-1 : 5-disulphonic acid, naphthalene-2 : 7-disulphonic acid, 2 : 6-dinitrobenzene-1 : 4-disulphonic acid, β -naphthol-6 : 8-disulphonic acid (but not with benzene-*m*-disulphonic acid, β -naphthol-3 : 6-disulphonic acid, and 3 : 5-disulphobenzonic acid), with 7-chloronaphthalene-1 : 3 : 6-trisulphonic acid, 5-nitronaphthalene-1 : 3 : 7-trisulphonic acid (but not with naphthalene-1 : 3 : 6-trisulphonic acid or 7-chloronaphthalene 1 : 3 : 6-trisulphonic acid).

T. Hamburger examined the effect of the hexammine on chromate-gelatine; H. G. B. de Jong, the gelatinization of agar-agar sol; and E. Funk, the action of the ammine on catalase and amylase ferments.

G. R. Levi found that cobaltic hexamminochloride forms **copper cobaltic hexamminopentachloride**, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot \text{CuCl}_2$; F. Ephraim and P. Mosimann, brownish-red crystals of hydrated zinc cobaltic hexamminopentachloride, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot \text{ZnCl}_2 \cdot \text{H}_2\text{O}$; hydrated cadmium cobaltic hexamminopentachloride, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot \text{CdCl}_2 \cdot \text{H}_2\text{O}$, in small, pale yellow crystals; and cadmium cobaltic hexamminoheptachloride, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot 2\text{CdCl}_2 \cdot 3\text{H}_2\text{O}$, as a brownish-yellow, crystalline powder of sp. gr. 2.366 at 25°, when the sp. gr. of the anhydrous salt is 2.411 at 25°. The salt was also examined by F. Ephraim and O. Schütz, and E. Birk. S. M. Jörgensen reported orange-coloured microscopic crystals of **mercuric cobaltic hexamminopentachloride**, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot \text{HgCl}_2$, which, according to F. Ephraim and O. Schütz, and E. Birk, have the sp. gr. 2.532 at 25°; J. M. Krok also described hydrated mercuric cobaltic hexamminoheptachloride, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot 2\text{HgCl}_2 \cdot 3\text{H}_2\text{O}$, and S. M. Jörgensen, mercuric cobaltic hexamminoenneachloride, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot 3\text{HgCl}_2 \cdot 3\text{H}_2\text{O}$. The complex salts with mercuric chloride were also studied by E. Carstanjen, G. Vortmann and E. Morgulis, Y. Shibata and T. Inoue, and T. Inoue. F. Ephraim and P. Mosimann prepared mercuric cobaltic hexamminotrichloropentacyanide, $[2\text{Co}(\text{NH}_3)_2]\text{Cl}_3 \cdot 5\text{HgCy}_3 \cdot \text{H}_2\text{O}$. C. D. Braun reported **stannous cobaltic hexamminodecachloride**, $2[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot 3\text{SnCl}_2 \cdot n\text{H}_2\text{O}$, and he obtained the *octohydrate*, and the *decahydrate*. E. Ephraim and P. Mosimann prepared pale yellow capillary needles of **lead cobaltic hexamminopentachloride**, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot \text{PbCl}_2$; and pale reddish-brown, 6-sided plates of **lead cobaltic hexamminoheptachloride**, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3 \cdot 4\text{PbCl}_2$. F. Ephraim and O. Schütz, and E. Birk found the sp. gr. to be 3.911 at 25°.

W. Feldt² prepared a **cobaltic hexahydroxylaminechloride**, $[\text{Co}(\text{NH}_2\text{OH})_6]\text{Cl}_3$, by the action of alcoholic hydrochloric acid on a suspension of cobaltous dihydroxylaminoychloride in alcohol, and strongly cooling the liquid; and A. Werner and E. Berl, by the action of a soln. of hydroxylamine chloride in potash-lye on cobaltic *trans*-dichlorobisethylenediaminochloride or on a soln. of cobaltic chlorohydroxylaminebisethylenediaminochloride. A. Fock found that the golden-yellow monoclinic crystals have the axial ratios $a : b : c = 0.9358 : 1 : -$, and $\beta = 84^\circ 7'$. According to A. Werner and E. Berl, the salt is stable towards hydrochloric acid, even during a prolonged boiling. The aq. soln. give a precipitate of the corresponding salt when it is treated with hydrobromic acid; a brown precipitate with hydriodic acid; and no precipitate with potassium iodide. Conc. sulphuric or nitric acid decomposes the salt at ordinary temp. No precipitate is formed when the soln. is treated with ammonium sulphate, sodium dithionate, potassium dichromate, mercuric chloride, or hydrochloroplatinic acid; there is a yellow or brown precipitate with potassium cyanide, ferrocyanide, or ferricyanide, sodium carbonate or acetate, or ammonium oxalate. The salt is not acted on by acetyl chloride; but boiling anhydrous acetic acid reduces it to a cobaltous salt; and benzaldehyde and salicylaldehyde form complex products. C. S. Borzekowsky prepared **cobaltic hydroxylaminebisethylenediamineamminochloride**, $[\text{Co}(\text{NH}_3)_2\text{en}_2(\text{NH}_2\text{OH})]\text{Cl}_3$, both in the dextro- and lævo-forms.

S. M. Jörgensen³ obtained **cobaltic trisethylenediaminechloride**, $[\text{Co en}_3]\text{Cl}_3$, by oxidizing a soln. of cobaltous chloride in ethylenediamine. The salt was also prepared by H. Grossmann and B. Schück, and L. L. Lehrfeld. The air-dried salt is the *trihydrate*, which becomes anhydrous over sulphuric acid, or at 100°.

M. Delépine and R. Charonnet obtained optically-active compounds of the chloride. F. M. Jäger found that the ditrigonal crystals have the axial ratio $a : c = 1 : 0.6667$; the sp. gr. 1.542 at 17° ; the mol. vol. 295.08; and the topi \bar{c} axial ratio $\frac{1}{2}\psi : \omega = 4.2129 : 5.6175$. R. Lorenz and I. Posen, and I. Posen calculated the sp. gr. in vacuo to be 1.5132, and the mol. vol. at absolute zero 233.8. E. N. Gapon studied the diffusion. A. Benrath and W. Kohlberg, and A. G. Bergmann measured the vap. press. and obtained indications of a *monohydrate*. H. Grossmann and B. Schück gave 256° for the m.p. Y. Shibata, R. Samuel and co-workers, Y. Shibata and G. Urbain, C. Schleicher, F. W. Beyer, A. Mead, and J. Angerstein measured the absorption spectra of aq. soln. G. Berger studied the photochemical decomposition of the salt. R. Lorenz and I. Posen found the equivalent conductivity, λ , for soln. of v litres per gram-equivalent, at 25° :

v	62	128	256	152	1024
λ	110.2	119.3	127.3	133.6	137.8

and at infinite dilution, $\lambda_\infty = 142.8$. A. Werner and C. Herty measured the mol. conductivity. R. Lorenz and I. Posen gave 0.512 for the transport number of the anion for $v=192$ at 20° ; and E. N. Gapon studied the subject. E. Rosenbohm found the magnetic susceptibility to be -4.90×10^{-7} mass unit. A. Rostkowsky found for the solubility, S mols. per cent.:

S	10°	20.3°	30°	50°	70°	90°	110°
	1.2	1.6	2.1	3.2	4.5	5.9	7.3

According to S. M. Jörgensen, with a 2 per cent. aq. soln., conc. nitric or hydrochloric acids give no precipitate; and conc. hydrobromic acid gives an incomplete precipitation; soln. of potassium iodide give no precipitate, but a soln. of iodine and potassium iodide gives a dark brown, crystalline precipitate. Yellowish- or reddish-brown precipitates are produced by mercuric chloride, sodium chloroplatinate, gold chloride, or potassium chloroplatinite, ferrocyanide or ferricyanide (with a few drops of dil. hydrochloric acid). When the aq. soln. is evaporated with nitric acid, the nitrate of the series is formed; nitrous acid has no action; boiling, 7 per cent. soda-lye does not decompose the salt; and ammonium sulphide does not give an immediate precipitation. G. and P. Spacu prepared **mercury cobaltic trisethylenediaminochlorides**, $[\text{Co en}_3](\text{HgCl}_3)_3$, and $[\text{Co en}_3]_2(\text{HgCl}_4)_3$; **bismuth cobaltic trisethylenediaminechloride**, $[\text{Co en}_3](\text{BiCl}_6) \cdot 2\text{H}_2\text{O}$.

According to A. Werner, there are two possible salts of triethylenediaminecobalt which stand to each other in the relation of object and mirror-image, and are not superposable. These may be represented as in Fig. 111. Such compounds form the simplest possible case of molecular asymmetry, being specially characterized by having all the co-ordination positions of the central atom occupied by structurally identical groups, the asymmetry being caused by the special spatial arrangement of these groups. This type of isomerism can be called *molecular asymmetry*.

FIG. 112.—A. Werner's Molecular Asymmetry.

A. Werner prepared the *dextro*-salt, and the *laevo*-salt. If the aq. soln. of the optically active bromide of the series ($q.v.$) be shaken with freshly-precipitated silver chloride, the filtrate evaporated, and then treated with alcohol, golden-yellow needles of the corresponding optically active cobaltic trisethylenediaminochloride are formed. A. Werner found the sp. rotation of a 1 per cent. soln. for yellow- and red-light is $[\alpha] = 152^\circ$ for the dextrorotatory form, and -154° for the laevorotatory form. E. Rosenbohm gave -4.54×10^{-7} for the magnetic susceptibility of the two forms. Measurements were also made by L. C. Jackson.

J. Meisenheimer and co-workers prepared hydrated **sodium cobaltic trisethylenediamineheptachloride**, $2[\text{Co en}_3]\text{Cl}_3 \cdot \text{NaCl} \cdot 6\text{H}_2\text{O}$, in yellowish-brown prisms from the chloride of the series mixed with soln. of sodium chloride; N. S. Kurnakoff likewise obtained hydrated **copper cobaltic trisethylenediaminopentachloride**, $[\text{Co en}_3]\text{Cl}_3 \cdot \text{CuCl}_2 \cdot \text{H}_2\text{O}$, in yellowish-

brown plates, sparingly soluble in water acidified with hydrochloric acid. The water of crystallization is given off at 112° , not at 100° . A. Werner and F. Bräunlich prepared **cobaltous cobalt trisethylenediaminooctachloride**, $2[\text{Co en}_3]\text{Cl}_3 \cdot \text{CoCl}_2 \cdot 4\text{H}_2\text{O}$, from a boiling soln. of the chloride of the series and an excess of cobalt chloride, acidified with hydrochloric acid. The emerald-green needles or prisms are decomposed by water. No water is lost over sulphuric acid, but all is lost at 110° . N. S. Kurnakoff prepared **cobaltous cobaltic trisethylenediaminepentachloride**, $[\text{Co en}_3]\text{Cl}_3 \cdot \text{CoCl}_2 \cdot 5\text{H}_2\text{O}$, by evaporating on a water-bath a soln. of 1 part of the chloride of the series, and 1 to 2 parts of cobaltous chloride. The brownish-violet liquid furnishes dark green needles or prisms. A. G. Bergmann also prepared **nickel cobaltic trisethylenediaminooctachloride**, $2[\text{Co en}_3]\text{Cl}_3 \cdot \text{NiCl}_2$.

P. Pfeiffer and T. Gassmann treated cobaltic chloropentamminochloride with propylenediamine monohydrate and obtained yellow, non-crystalline **cobaltic trispropylenediaminoochloride**, $[\text{Co pn}_3]\text{Cl}_3$, when pn stands for $\text{C}_3\text{H}_5(\text{NH}_2)_2$. F. M. Jäger and H. B. Blumendal prepared small, blood-red crystals of **cobaltic tritranscyclopentanediaminoochloride**, $[\text{Co}(\text{C}_5\text{H}_9\text{N}_2)_3]\text{Cl}_3 \cdot 3\text{H}_2\text{O}$ by the action of transcyclopentanediamine on cobaltic dichloroditranscyclopentanediaminoochloride. The triclinic crystals have the axial ratios $a : b : c = 2.2474 : 1 : 1.5625$. By the action of the active tartratochloride of the series on the active iodide, the *trihydrate* of the optically active salt is produced in hexagonal pyramids with the axial ratio $a : c = 1 : 2.5328$, and sp. gr. 1.364 at 20° . The *tetrahydrate* forms regular crystals. F. M. Jäger and H. B. Blumendal obtained the optically active **cobaltic tris-cyclopentanediaminoochloride**, in brick-red, octahedral crystals, by the action of *l*-cyclopentanediamine on cobaltic chloropentamminochloride. The *trihydrate*, and *tetrahydrate* were prepared. F. G. Mann and W. J. Pope heated on a water-bath a soln. of triaminopropanetrihydrochloride in 15 per cent. soda-lye with cobaltic chloropentamminochloride or aquopentamminochloride, and obtained optically inactive **cobaltic tris-triaminopropanechloride**, $[\text{Co}\{\text{C}_3\text{H}_5(\text{NH}_2)_3\}_3]\text{Cl}_3$, in orange-red needles which melt at 312° to 314° with decomposition; they are soluble in water. The optically active *dextro-salt* was obtained from the α -camphor- β -sulphonate of the series.

A. Werner prepared **cobaltic cis-bisethylenediaminediamminoochloride**, $[\text{Co en}_2(\text{NH}_3)_2]\text{Cl}_3$, by treating with perhydrol and hydrochloric acid, a soln. of a salt of cis-bisethylenediaminodithiocyanatoammine, and evaporating the liquid. R. Plischke prepared **cobaltic bisethylenediaminepyridineamminoochloride**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{py}]\text{Cl}_3$. Optically active forms were prepared by A. Werner and Y. Shibata from the *l*-bromo camphor sulphonate. The golden-yellow crystals of the *dextro-salt* have $[\alpha] = 50^\circ$ and 15° for yellow- and red-light, and the *laevo-salt*, -51° and -16° . A. Werner and C. Kreutzer obtained **cobaltous cobaltic cis-bisethylenediaminediamminopentachloride**, $[\text{Co en}_2(\text{NH}_3)_2]\text{Cl}_3 \cdot \text{CoCl}_2$. A. Werner and co-workers, W. Tupizina, and K. R. Lange prepared **cobaltic trans-bisethylenediaminediamminoochloride**, $[\text{Co en}_2(\text{NH}_3)_2]\text{Cl}_3 \cdot \text{H}_2\text{O}$, by oxidizing the trans-form of salt employed in preparing the cis-modification. The salt furnishes amber-yellow, thick plates, stable in air; H. Grossmann and B. Schück said that the pale yellow, needle-like crystals effloresce in air. F. M. Jäger and co-workers said that the monoclinic prisms have the axial ratios $a : b : c = 2.7565 : 1 : 1.3677$, and $\beta = 101^\circ 48'$, and have no perceptible cleavage. The sp. gr. is 1.659 at 17° ; the mol. vol. 203.43; and the topic axial ratios $\chi : \psi : \omega = 10.4930 : 3.8058 : 5.2052$. R. Lorenz and I. Posen gave 1.6426 for the sp. gr. reduced to a vacuum, and for the anhydrous salt they gave 1.644. H. Grossmann and B. Schück gave 252° for the m.p. C. Schleicher, A. Gordienko, and Y. Shibata and G. Urbain studied the absorption spectrum. R. Lorenz and I. Posen found the eq. conductivity, λ , for a gram-equivalent of the salt, in litres, at 25° :

v	.	.	.	64	128	256	512	1024
λ	.	.	.	117.1	126.5	134.7	141.4	147.7

and for infinite dilution $\lambda_\infty = 149.9$. Measurements were also made by A. Werner and C. Herty. R. Lorenz and I. Posen found the transport number of the anion to be 0.496 at 19° when $v = 90$. A. Werner and co-workers found that nitric acid, hydrobromic acid, and potassium iodide precipitate the corresponding salt of the series; whilst hydrochloroplatinic acid, gold chloride, mercuric chloride, stannous chloride and hydrochloric acid, and potassium chloroplatinite gave a dark yellow, crystalline precipitate. A. Werner and co-workers also prepared **gold cobaltic bisethylenediaminediamminoeneachloride**, $[\text{Co}(\text{NH}_3)_2\text{en}_2]\text{Cl}(\text{AuCl}_4)_2$, and **gold cobaltic bisethylenediaminediamminohexachloride**, $[\text{Co}(\text{NH}_3)_2\text{en}_2]\text{Cl}_2(\text{AuCl}_4)_2$, in yellow plates; mercuric cobaltic trans-bisethylenediaminediamminotridecachloride, $[\text{Co en}_2(\text{NH}_3)_2]\text{Cl}_3 \cdot 5\text{HgCl}_2$, in yellow, needle-like crystals; and hydrated **cobaltous cobaltic transbisethylenediaminediamminopentachloride**, $[\text{Co en}_2(\text{NH}_3)_2]\text{Cl}_3 \cdot \text{CoCl}_2 \cdot 2\text{H}_2\text{O}$, in thin plates which are brownish-red in transmitted light, and dark green, almost black, in reflected light.

A. Werner and K. Dawe prepared **cobaltic bispropylenediaminediamminoochloride**, $[\text{Co pn}_2(\text{NH}_3)_2]\text{Cl}_3$, by passing chlorine into a soln. of a salt of cobaltic dithiocyanatobispropylenediaminoochloride. The golden yellow, 6-sided prisms are very soluble in water, but the addition of alcohol or ether precipitates the salt from the aq. soln. Hydrochloric acid does not precipitate the chloride from the aq. soln. Hydrobromic, or nitric

acid, potassium bromide or iodide, and sodium dithionate precipitate the corresponding salt from the aq. soln.; potassium dichromate, ferrocyanide or ferricyanide, gold chloride, mercuric chloride or stannous chloride and hydrochloric acid give pale yellow or reddish-yellow, crystalline precipitates; picric acid gives a lemon-yellow precipitate; potassium permanganate, yellow plates; and cobaltous chloride, a green double salt; whilst ferrous chloride, cuprous chloride, zinc chloride, ammonium oxalate, sodium hydrophosphate, and sodium acetate give no precipitates. Needle-like or prismatic crystals of **mercuric cobaltic bispropylenediaminediammineheptachloride**, $[\text{Co} \text{pn}_2(\text{NH}_3)_2]\text{Cl}_3 \cdot 2\text{HgCl}_2$, were prepared; also yellowish-red crystals of **stannous cobaltic bispropylenediaminediammineheptachloride**, $[\text{Co} \text{pn}_2(\text{NH}_3)_2]\text{Cl}_3 \cdot 2\text{SnCl}_2$; and pale green plates of hydrated **cobaltous cobaltic bispropylenediaminediamminopentachloride**, $[\text{Co} \text{pn}_2(\text{NH}_3)_2]\text{Cl}_3 \cdot \text{CoCl}_2 \cdot 2\text{H}_2\text{O}$. W. A. Re-deker prepared **cobaltic pyridinebisethylenediamineamminochloride**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{py}]\text{Cl}_3$.

F. M. Jäger and H. B. Blumendal prepared **cobaltic ethylenediaminebis-cyclopentanediaminechloride**, $[\text{Co} \text{en}(\text{C}_5\text{H}_{12}\text{N}_2)_2]\text{Cl}_3 \cdot 3\text{H}_2\text{O}$, by heating cobaltic trans-dichlorobis-cyclopentanediaminechloride with a 10 per cent. soln. of ethylenediamine. They also prepared **cobaltic bisethylenediamine-trans-cyclopentanediaminechloride**, $[\text{Co} \text{en}_2(\text{C}_5\text{H}_{12}\text{N}_2)]\text{Cl}_3 \cdot 3\text{H}_2\text{O}$, by heating cobaltic dichlorobisethylenediaminechloride, or aquochlorobisethylenediaminechloride with cyclopentanediamine; and also **cobaltic bisethylenediamine-l-cyclopentanediaminechloride** by heating cobaltic dichlorobisethylenediaminechloride with l-cyclopentanediamine. F. M. Jäger and P. Koets prepared **cobaltic sexiesethylenediamine-bistriaminotriethylamine-enneachloride**, $[\text{Co}_3 \text{en}_6(\text{C}_6\text{H}_{18}\text{N}_4)_2]\text{Cl}_3 \cdot 4\text{H}_2\text{O}$, by the action of triaminotriethylamine on a soln. of cobaltic aquochlorobisethylenediaminechloride. C. J. Dippel and F. M. Jäger prepared **cobaltic trisdiaminopentanochloride**, $[\text{Co} \text{ptn}_3]\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, with $\alpha\beta\delta$ - and $\beta\beta\delta$ -diaminopentanes.

O. W. Gibbs and F. A. Genth⁴ prepared **cobaltic roseochloride**, **cobaltic aquopentamminochloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_3$, by oxidizing an ammoniacal soln. of cobaltous chloride in air, and adding hydrochloric acid to the cold liquid. If the warm soln. is treated with hydrochloric acid, cobaltic chloropentamminochloride is precipitated, but if the acid be added slowly, and the soln. be kept very cold, the aquopentamminochloride is deposited. J. M. Krok oxidized the soln. with chlorine; and E. J. Mills, with permanganate. F. Rose recommended shaking a cobaltic chloropentamminochloride with hot, 5 per cent., aq. ammonia, and dropping the cold liquid into an equal vol. of conc. hydrochloric acid; and a similar process was employed by A. Benrath, N. R. Dhar, and R. Pers; S. M. Jörgensen, and O. W. Gibbs used the nitratopentamminonitrate in place of the chloro-salt; and S. M. Jörgensen, and O. Hassel and J. R. Salvesen, the oxalato-salt. H. and W. Biltz thus describe the preparation of this salt:

A cold soln. of 20 grms. of hydrated cobalt chloride in 360 c.c. of water, in a 1500-c.c. flask, is mixed with 110 c.c. of conc. aq. ammonia, and then with 10 grms. of potassium permanganate dissolved in 400 c.c. of water. The mixture is well agitated, and after standing 24 hrs., it is filtered to remove the hydrated manganese dioxide. The filtrate is neutralized with dil. hydrochloric acid, and, while keeping it cold with ice, a mixture of 3 vols. of hydrochloric acid and 1 vol. of alcohol is added. The precipitate is washed with alcohol; the yield is 10 grms. The crude product is then dissolved in cold, 2 per cent. aq. ammonia, using 75 c.c. for each 10 grms. of salt. Filter off the slight residue of the hexamminochloride, and, whilst keeping the soln. cold with ice, gradually add conc. hydrochloric acid. Drain the precipitate, wash it with a 1:1 mixture of hydrochloric acid and water, then with alcohol, and dry the product in a warm place.

The crystalline powder is brick-red and dichroic. H. V. Arny and C. H. Ring recommended an ammoniacal 0.1N-soln. as a standard in comparing red colour tints. F. Ephraim and O. Schütz found the sp. gr. to be 1.743 at 25°, and the mol. vol. 154-l. There is a vol. contraction of 67 per cent. during the formation of the salt. E. Birk found for the sp. gr. 1.745 at 25°/4°, and for the mol. vol. 153.8. R. Lorenz and I. Posen, and I. Posen gave 1.7629 for the sp. gr. reduced to a vacuum. G. L. Clark and co-workers gave 1.776 for the sp. gr., 151.29 for the mol. vol., 16.20 for the mol. vol. of the contained NH_3 -groups, and 14.05 for the contained H_2O -group. J. Petersen calculated the mol. wt., 226, from the f.p. of aq. soln. of the salt. J. N. Brönsted and K. Volquartz studied the ionization. O. W. Gibbs and F. A. Genth, and A. Werner observed that the solid salt slowly changes into cobaltic chloropentamminochloride, and A. B. Lamb and J. W. Marden added that the transformation is irreversible and is attended by the loss of a mol. of water.

At 25°, the water vapour of aquopentamminochloride has a critical press. of 5.1 mm. The solid salt is not a stable phase at 25° in water or in hydrochloric acid. The transformation of the aquopentammine into chloropentammine in aq. soln. was studied by O. W. Gibbs and F. A. Genth, and E. J. Mills. A. Benrath and K. Mienes observed that the transformation proceeds more slowly as the concentration of the hydrochloric acid increases. A. B. Lamb and J. W. Marden found that in aq. soln., in soln. containing chlorides, and in hot, dil. hydrochloric acid soln., a state of equilibrium is attained; at 70°, a 0.02*M*-soln. of the aquo-pentammine or chloropentammine in the presence of 0.02*M*-HCl, contains 70.5 per cent. of the aquopentammine, and in the presence of 0.1*M*-HCl, 65 per cent. in 20 hrs. no matter which salt is employed at the start. R. Pers said that in boiling, dil. hydrochloric acid, the equilibrium constant, $K=1.4$, corresponding with 58 per cent. of the aquopentammine, and 42 per cent. of the chloropentammine. P. Job observed that in alkaline soln., the aquopentammine passes quantitatively into the hydroxypentammine. A. B. Lamb and A. T. Larson studied the relative stability of soln. of many of the amines—*vide supra*, hexamminochloride. A. B. Lamb and J. P. Simmons gave -6.46 Cals. for the mol. heat of solution in water at 25°. The absorption spectra of aq. soln. were studied by A. N. Nikolopulos, R. Luther and A. N. Nikolopulos, Y. Shibata, Y. Shibata and G. Urbain, and E. Valla; and the X-ray spectrum, by F. de Boer. A. Werner and A. Miolati measured the mol. conductivity, μ , at 25°, and found for a mol of the salt in *v* litres:

<i>v</i>	128	256	5.12	1024	2048
μ	330.6	354.7	381.4	393.7	410.4

R. Lorenz and I. Posen measured the eq. conductivity; and J. Petersen obtained for a gram-equivalent of the salt in *v* litres, the following values for the degree of ionization, α , and for the factor i or n (1, 15, 10):

<i>v</i>	1	2	5	10	50	100	1000
α	0.55	0.62	0.66	0.73	0.79	0.86	0.97
<i>i</i>	2.65	2.86	2.98	3.19	3.37	3.58	3.91

A. B. Lamb and A. T. Larson studied the oxidation potential, and N. R. Dhar and G. Urbain, the polarization tension—*vide supra*, the hexamminochloride. O. W. Gibbs and F. A. Genth observed that the boiling of a neutral soln. is attended by the deposition of cobaltous hydroxide; and A. B. Lamb and J. W. Marden, that the soln. feebly acidified with hydrochloric acid is slowly hydrolyzed at 100°; and R. Schwarz and co-workers, that an aq. soln. at ordinary temp. is hydrolyzed when exposed to ultra-violet rays. N. R. Dhar and G. Urbain measured the polarization tension—*vide supra*, the hexamminochloride. H. Moehle studied the magnetic properties of the salt.

N. S. Kurnakoff found that 100 parts of water dissolve 16.2 parts of cobaltic aquopentamminochloride at 0°, and 24.87 parts at 16.9°; and F. Ephraim observed that a sat. soln. at 17.5° contains 0.859 mol per litre. S. M. Jörgensen observed that the addition of sulphuric acid gives no precipitate, and he observed no reaction with dil. hydrochloric or hydrobromic acid, sodium dithionate, and hydrophosphate. F. Ephraim found that a current of ammonia acts on the salt at -21°, forming a purple-red **cobaltic aquohenamminochloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_3.6\text{NH}_3$, which, at -8.5°, furnishes a bluish-red powder of **cobaltic aquoctamminochloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_3.3\text{NH}_3$, and as the temp. rises, this product passes into **cobaltic aquoheptamminochloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_3.2\text{NH}_3$, which, as the temp. rises to 38.5°, passes into **cobaltic aquohexamminochloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_3.\text{NH}_3$, and this red salt is stable up to 66°. H. Freundlich and H. Schucht observed that a sol. of arsenic trisulphide is flocculated by cobaltic aquopentamminochloride. A. B. Lamb and J. P. Simmons gave -6460 cal. for the mol. heat of soln. J. N. Brönsted and K. Volquartz studied the effect of the salt on the decomposition

of nitramide; and J. N. Brönsted, the behaviour of the salt in acid and base catalysis. S. M. Jörgensen, O. W. Gibbs and F. A. Genth, and E. J. Mills found that a soln. of cobaltic aquopentamminochloride gives no precipitate with hydrofluosilicic acid, but it gives yellowish-red precipitates with potassium iodide, ammonium oxalate, potassium chromate or dichromate, chloroaurate, and ferrocyanide, or with sodium pyrophosphate. P. Job found that all the chloride is precipitated by silver nitrate from aq. soln. of the salt.

O. W. Gibbs reported **gold cobaltic aquopentamminohexachloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_2(\text{AuCl}_4)$, in orange-red crystals, by the action of sodium chloroaurate on a soln. of the aquopentamminochloride; F. Ephraim and co-workers obtained **zinc cobaltic aquopentamminopentachloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_3\cdot\text{ZnCl}_2$, as a red salt from a soln. of 1 mol. of the aquopentammine acid, and 10 mols. of zinc chloride; also **cadmium cobaltic aquopentammineheptachloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_3\cdot 2\text{CdCl}_2\cdot 3\text{H}_2\text{O}$, as a pale rose-red, crystalline powder of sp. gr. 2.434 at 25°, and mol. vol. 283, which corresponds with a contraction of 57 per cent. in the formation of the salt. The subject was studied by E. Birk. S. M. Jörgensen prepared **mercuric cobaltic aquopentamminopentachloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_3\cdot\text{HgCl}_2$, by adding mercuric chloride to a strongly acidic soln. of the aquopentammine. By re-crystallization from aq. soln., **mercuric cobaltic aquochloropentamminoenneachloride**, $[\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_5]\text{Cl}_3\cdot 3\text{HgCl}_2\cdot \text{H}_2\text{O}$, is formed, and also, along with a double salt, with chloropentamminochloride, $[\text{Co}(\text{NH}_3)_5]\text{Cl}_3\cdot 3\text{HgCl}_2$, by treating a boiling, feebly acidic soln. of chloropentamminochloride, with a hot soln. of mercuric chloride, and subsequently separating the two double salts by fractional crystallization. The salt was also prepared by O. W. Gibbs. It furnishes violet prisms. It is decomposed by cold, conc. hydrochloric acid, and it loses all its water at 100°. E. Carstanjen reported a pentahydrate, but this was not confirmed by O. W. Gibbs, or S. M. Jörgensen.

S. M. Jörgensen treated an ice-cold, 20 per cent. soln. of cobaltic carbonatetetramminochloride with dil. hydrochloric acid, and then with conc. hydrochloric acid, thereupon, **cobaltic diaquotetramminochloride**, $[\text{Co}(\text{H}_2\text{O})_2(\text{NH}_3)_4]\text{Cl}_3$, is deposited in small, dark red, octahedral crystals. E. Birk also prepared the salt in this manner, and A. Werner, by the action of cold conc. hydrochloric acid on a dodecammino-hexahydroxy-salt, or an octamminodihydroxy-salt. G. Vortmann reported a monohydrate to be formed by adding hydrochloric acid to an oxidized ammoniacal soln. of cobalt carbonate. E. Birk, and W. Biltz found the sp. gr. to be 1.783 at 25°/4°, and the mol. vol. 151.1. R. Lorenz and I. Posen, and I. Posen calculated 1.8363 for the sp. gr. in vacuo. According to S. M. Jörgensen, when the salt is heated to 100°, it passes into aquochlorotetramminochloride; and A. Werner added that the same change occurs very slowly at ordinary temp. J. N. Brönsted and K. Volquartz studied the ionization of the salt. A. Benrath and K. Andreas observed that the solid is not stable in contact with a sat. aq. soln., or dil. hydrochloric acid soln., but passes into the chloro-aquotetrammine, and this the more slowly, the more concentrated is the acid. P. Job found that in contact with barium hydroxide, the $2\text{H}_2\text{O}$ -groups are replaced by two OH-groups. A. B. Lamb and A. T. Larson studied the stability of the salt in ammoniacal soln.—*vide supra*, the hexamminochloride. The absorption spectra were studied by A. N. Nikolopulos, R. Luther and A. N. Nikolopulos, Y. Shibata, Y. Shibata and G. Urbain, K. Matsuno, and E. Valla. R. Lorenz and I. Posen, and I. Posen found the equivalent conductivity, λ , for soln. with a gram-equivalent in v litres at 0.6°:

v	.	.	.	64	128	256	512	1024
λ	.	.	.	54.37	57.70	61.08	64.30	66.77

and at the limit, $\lambda_\infty = 71.6$. R. Schwarz and K. Tede noted that the salt in aq. soln. is hydrolyzed on exposure to ultra-violet rays. A. B. Lamb and A. T. Larson studied the oxidation potential; and N. R. Dhar and G. Urbain, the polarization tension—*vide supra*, the hexamminochloride. F. Ephraim found that a sat. aq. soln. at 22° contains 1.83 mols per litre; and A. Benrath and K. Andreas noted that the solubility is 3.83, which drops to 0.20 when 29.08 per cent. hydrochloric acid is present. A. Werner found that in dil. acetic acid soln., pyridine forms a complex dodecammine. J. N. Brönsted and K. Volquartz studied the effect of the

salt on the decomposition of nitramide. G. Vortmann prepared **mercuric cobaltic diaquotetramminochloride**.

A. Werner and co-workers, and J. D. Dubsky prepared hydrated **cobaltic cis-diaquobisethylenediaminechloride**, $[\text{Co en}_2(\text{H}_2\text{O})_2]\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, by hydrating cis-dichlorobisethylenediaminechloride; by the action of hydrochloric acid on sexesethylenediaminehexahydroxy-nitrate, or on quaterethylenediaminetetrahydroxysulphate. The compound passes into violet dichlorobisethylenediaminechloride on keeping; it loses 4 mols. of water in vacuo over phosphorus pentoxide, or at 115° , so as to form the violet dichlorobisethylenediaminechloride. It forms a yellowish-red soln. with water. K. Matsuno, and A. Uspensky and K. Tschibisoff studied the absorption spectrum. According to A. Werner, when the salt is treated with dil. potash-lye, brownish-red $[\text{Co en}_2(\text{H}_2\text{O})(\text{OH})]\text{Cl}_2$ is formed; with sodium nitrite, $[\text{Co en}_2(\text{NO}_2)(\text{NO}_2)]$ is formed. A. Werner and co-workers also prepared hydrated **cobaltic trans-diaquobisethylenediaminechloride**, $[\text{Co en}_2(\text{H}_2\text{O})_2]\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, by the action of conc. hydrochloric acid on cobaltic trans-aquohydroxybisethylenediaminebromide. It passes into the violet form of dichlorobisethylenediaminechloride on keeping, and if a trace of acid is present, the green form. K. Matsuno, and A. Uspensky and K. Tschibisoff studied the absorption spectra. A. Werner prepared **cobaltic diaquodipyridinediamminochloride**, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_2\text{py}_2]\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, by the action of conc. hydrochloric acid on the aquohydroxydipyridinediamminochloride.

A. Werner prepared **cobaltic cis-triaquotriamminochloride**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_3]\text{Cl}_3$, by allowing a trinitratotriammino-salt to stand for 24 hrs. in contact with acetic acid, and adding hydrochloric acid, saturated at 0° , to the ice-cold filtered liquid. The pale violet, crystalline powder is separated quickly, since if allowed to stand in contact with the mother-liquor, it changes into dichloroetraquotriamminochloride. E. Birk, and W. Biltz gave 1.8114 for the sp. gr. at $25^\circ/4^\circ$, and 149.1 for the mol. vol. N. R. Dhar and G. Urbain studied the polarization tension—*vide supra*, the hexamminochloride; J. N. Brönsted and K. Volquartz, the ionization; R. Schwarz and K. Tede, the hydrolysis of the aq. soln. by exposure to ultra-violet rays; K. Matsuno, the absorption spectrum; J. N. Brönsted and K. Volquartz, the effect of the salt on the decomposition of nitramide; H. Freundlich and H. Schucht, the flocculation of a sol of arsenic sulphide by the salt; and A. Werner, the precipitation of the chloride-ions by soln. of silver nitrate. By evaporating an aq. soln. of cobaltic dichloroetraquotriamminechloride in water acidified with hydrochloric acid, the soln. changes from bluish-violet to reddish-violet as it forms the isomeric **cobaltic trans-triaquotriamminochloride**. The absorption spectrum was studied by K. Matsuno. The dissociation tension of **cobaltic tetraquodiamminochloride**, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_4]\text{Cl}_3$, was studied by N. R. Dhar and G. Urbain, and the ionization by J. N. Brönsted and K. Volquartz.

The CoA₅ or Pentammine Family.

In 1851, F. Claudet,⁵ and F. A. Genth described the first of the pentammine series of cobaltic chlorides. F. Claudet's analysis gave $\text{CoN}_5\text{H}_{16}\text{Cl}_3$, and E. Frémy's, $\text{CoN}_5\text{H}_{15}\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, but the analysis of W. Gregory, B. J. Rogojsky, and O. W. Gibbs and F. A. Genth agreed that the composition is correctly represented by $\text{CoN}_5\text{H}_{15}\text{Cl}_3$; and the work of S. M. Jörgensen, A. Werner, J. A. N. Friend, and E. E. Turner indicated that, constitutionally, the compound is **cobaltic chloropentamminochloride**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$. F. Claudet, and F. A. Genth prepared the salt by oxidizing, with air or oxygen, an ammoniacal soln. of cobaltous and ammonium chlorides, and precipitating the product with hydrochloric acid. E. J. Mills employed potassium permanganate as oxidizing agent, and C. D. Braun, indigo-blue in a boiling soln. The salt was prepared, by these methods, by J. M. Krok, C. Künzel, B. J. Rogojsky, H. Schiff, A. Terreil, and W. D. Harkins and co-workers. J. H. Buckminster and E. F. Smith oxidized the ammoniacal soln. of cobaltous chloride, in the presence of ammonium sulphate and potassium chromate, electrolytically, and then precipitated the salt by the addition of hydrochloric acid. O. W. Gibbs and F. A. Genth prepared the salt by boiling cobaltic aquopentammine nitrate, or nitroxylpentamminonitrate, with hydrochloric acid; and W. Biltz,

by heating cobaltic hexamminochloride at 225° , in a current of ammonia. H. and W. Biltz, S. P. L. Sörenson, and W. D. Harkins and co-workers proceed somewhat as follows:

A cold, filtered soln. of 20 grms. of cobaltous carbonate in as little hydrochloric acid as possible, is treated with 250 c.c. of 10 per cent. ammonia, and 50 grms. of ammonium carbonate in 250 c.c. of water. Air is passed through the mixture for 3 hrs. and then 150 grms. of ammonium chloride are added and the soln. evaporated on a water-bath to a syrupy liquid. The mixture is then acidified with hydrochloric acid to drive off the carbon dioxide, the acid is neutralized with ammonia, and 10 c.c. of conc. ammonia in excess are added. Dilute the mixture to 400 or 500 c.c., and warm the soln. on a water-bath for one hour. Add 300 c.c. of conc. hydrochloric acid, and allow the soln. to stand on a water-bath for 30 to 45 minutes. The crystals are then filtered off from the cold liquid and washed with dil. hydrochloric acid. The salt can be purified by digesting it in 300 c.c. of a 2 per cent. soln. of ammonia, extracting the residue twice with 50 c.c. of the same ammonia soln., and precipitating the salt by adding 300 c.c. of conc. hydrochloric acid, and keeping the mixture on a water-bath for about 45 minutes. When cold, the soln. is filtered, and the precipitate washed with dil. hydrochloric acid and alcohol.

Cobaltic chloropentamminochloride furnishes violet-red or purple crystals. M. G. Mellon recommended the aq. soln. as a standard colour in colorimetry. The crystals are rhombic bipyramids, having, according to H. Töpsöe, and F. M. Jäger, the axial ratios $a:b:c=0.9825:1:1.5347$. J. D. Dana wrongly described the crystals as tetragonal; he gave 1.802 for the sp. gr. at 23° ; F. M. Jäger gave 1.836 at 10° ; the mol. vol. 136.05, and the topic axial ratios $\chi:\psi:\omega=4.4067:4.4852:6.8834$; S. M. Jørgensen, 1.802 to 1.808 at $25^{\circ}/4^{\circ}$; F. Ephraim and O. Schütz, 1.783 at 25° , and mol. vol. 140.5; and E. Birk, 1.787 at $25^{\circ}/4^{\circ}$, and mol. vol. 140.2. R. Klement discussed these results. R. Lorenz and I. Posen calculated 1.7696 for the sp. gr. in vacuo, and 142.7 for the mol. vol. at absolute zero. G. L. Clark and co-workers calculated 16.29 for the mol. vol. of each NH_3 -group in the complex. Z. H. Skraup and co-workers studied the capillary rise of aq. soln.; and E. N. Gapon, the diffusion. A. B. Lamb and J. W. Marden found that the salt is very stable, and suffered no change when kept for a year. J. S. Böhm and A. Dorabalska observed a heat effect with the salt. F. Rose represented the thermal decomposition of the salt by the equation: $6[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2=6\text{CoCl}_2+6\text{NH}_4\text{Cl}+22\text{NH}_3+\text{N}_2$, and the reaction has been utilized in the preparation of cobaltous chloride of a high degree of purity—G. P. Baxter and F. B. Coffin, W. Biltz, O. Ruff and E. Ascher, E. Ascher, etc. S. M. Jørgensen found that the salt in aq. soln. passes into the aquopentamminochloride, and in feebly acidic soln.; R. Pers observed a state of equilibrium, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2+\text{H}_2\text{O}\rightleftharpoons[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{Cl}_3$; and H. Freundlich and H. Pape, and E. A. Moelwyn-Hughes showed that the reaction is unimolecular. In a boiling soln., for equilibrium, the soln. contains 42 per cent. of the chloropentammine, and 58 per cent. of the aquopentammine, and A. B. Lamb and J. W. Marden observed that at 70° , in soln. with 0.005 to 0.05 mol of salt per litre, and 0.01 to 0.16N-HCl, there is present 61 to 78 per cent. of the aquopentammine; the hydration progresses slowly at 25° , and the reaction is unimolecular; with soln. having 0.004 mol per litre, the velocity constant, k , is 0.046. The subject was studied by A. Benrath, J. N. Brønsted and R. Livingston, K. Matsuno, and H. Freundlich and co-workers. N. R. Dhar observed that OH' -ions accelerate the hydration process; and O. W. Gibbs and F. A. Genth, that acids retard the reaction. A. B. Lamb and J. P. Simmons calculated the heat of the reaction to be 2.14 Cals. at 25° ; and the mol. heat of soln. of the salt in water as -12.42 Cals. at 25° . W. D. Harkins calculated for soln. with 0.002, 0.005, and 0.10 gram-equivalents, per litre, the mol. lowering of the f.p., 5.44, 5.357, and 5.178, respectively; for the factor i or $n=1.15$, 10—2.93, 2.883, and 2.787, respectively; and for the percentage ionization, 95.6, 92.8, and 89.3, respectively. The absorption spectrum was studied by J. Angerstein, R. Samuel and co-workers, M. Chatelet-Lavollay, R. Lorenz, A. N. Nikolopoulos, Y. Shibata, and E. Valla; the X-ray spectrum, by O. Stelling, and S. Aoyama and

co-workers; and the Raman effect, by D. M. Bose and S. Datta. A. Werner and A. Molati found the mol. conductivity of soln. at 25°, and R. Lorenz and I. Posen, and I. Posen, the eq. conductivity, at 18°. W. D. Harkins and co-workers gave for the eq. conductivity, λ , of soln. with C gram-equivalents per litre :

C	.	0.0178	0.008384	0.003728	0.0008891	0.0003021
λ	{ 0°	65.00	69.15	72.8	75.25	77.0
	{ 25°	120.7	130.2	126.8	142.8	144.7

R. Lorenz and I. Posen gave at the limit $\lambda_{\infty}=124.1$ at 18°. For the percentage ionization of soln. with 0.002, 0.005, and 0.010, gram-equivalent per litre, the percentage ionization, respectively, 96.0, 94.2, and 89.4, *vide supra*, f.p. data. A. B. Lamb and J. W. Marden—*vide supra*—calculated the degree of hydrolysis from conductivity data. R. Pers studied the dynamics of the hydrolysis: $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2 + \text{H}_2\text{O} \rightleftharpoons [\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{Cl}_3$. According to R. Schwarz and K. Tede, the hydrolysis: $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2 + 3\text{H}_2\text{O} = \text{Co}(\text{OH})_3 + 3\text{NH}_4\text{Cl} + 2\text{NH}_3$, proceeds in darkness at an immeasurably slow rate, but in light it proceeds at a speed corresponding with a reaction of the first order. After 60 minutes' exposure to ultra-violet light, a 0.001*M*-soln., at 25°, had suffered a 3.5 per cent. decomposition, and the velocity constant was $k=0.0469$. G. Berger studied the catalytic effect of neutral salts on the photochemical reaction. R. Lorenz found that the transport number of the anion for $v=80$, is 0.547 at 17.4°, and 0.549 at 20°; and E. N. Gapon studied the subject. N. R. Dhar and G. Urbain measured the polarization tension, and H. Freundlich and G. Ettisch, the electrokinetic potential—*vide* the hexamminochloride. E. Feytis found that the magnetic susceptibility of the solid is -0.295×10^{-6} mass unit; S. Berkman and H. Zocher, -0.53×10^{-6} mass unit; and E. Rosenbohm, -0.298×10^{-6} mass unit. The magnetic properties were also studied by W. Biltz, L. C. Jackson, D. M. Bose, and H. Moehle.

F. Claudet, and S. M. Jørgensen noted the solubility of the salt in water, and A. Werner observed that 100 grms. of water, at 11.5°, dissolve 0.4 gm. of the chloropentammine; and N. S. Kurnakoff said that 0.232 gm. is dissolved at 0°, and 1.031 grms. at 46.6°. A. B. Lamb and J. P. Simmons found that a litre of water at 0°, 29.7°, and 50°, dissolves, respectively, 2.244, 6.047, and 10.01 grms. F. Ephraim found that a sat. soln. has 0.0170 mol per litre at 19°; and J. N. Brønsted and A. Petersen, 0.00914 mol at 0°, and 0.018 mol at 20°. A. R. Klein studied the action of water, acids, and alkali-lye; and J. N. Brønsted and co-workers, the effect of potassium hydroxide, on various salts on the solubility in aq. and in methanol soln.; and A. Benrath, the effect of hydrochloric acid, potassium iodide, and mercuric chloride. O. W. Gibbs and F. A. Genth found that the salt is decomposed when boiled for a long time with water. O. Ruff and E. Ascher noted that the salt is decomposed by hydrogen chloride. A. Benrath found that at 25°, the following proportions of hydrochloric acid dissolve cobalt in the form of the chloropentamminochloride per 100 grms. of water :

HCl	0.00	0.20	0.60	1.00	2.00	4.00	10.00	30.00 per cent.
Co	0.1337	0.0599	0.0270	0.0200	0.0147	0.0065	0.0040	0.0029

and there is no sign of the formation of a double salt with hydrogen chloride. A. Benrath and H. Pitzler studied the reaction with hydrobromic acid: $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2 + 2\text{HBr} \rightleftharpoons [\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Br}_2 + 2\text{HCl}$. F. Ephraim observed that the salt is decomposed by sulphuric acid with the evolution of hydrogen chloride, and that ammonia is not taken up by the chloropentammine at -21° . G. T. Morgan and J. D. M. Smith observed that aq. ammonia in an autoclave, at 120°, converts the chloropentammine into the hexammine; and A. Benrath and K. Mienes found the reaction proceeds very slowly, and begins at about 150°. O. W. Gibbs and F. A. Genth noted that nitrous acid converts the chloropentammine into nitropentammine. H. Freundlich and H. Schucht, and K. Matsuno studied the flocculating action on the hydrosol of arsenic sulphide. F. Ephraim observed that

precipitates are produced by the substituted benzene and naphthalene sulphonic acids. As indicated above, the effect of potassium hydroxide on the solubility of the chloropentammine was studied by J. N. Brönsted and co-workers; and the formation of hydrated cobaltic oxide by the alkali-lye was observed by G. F. Hüttig and R. Kassler. According to O. W. Gibbs and F. A. Genth, and S. M. Jörgensen, coloured, crystalline precipitates are produced by potassium ferrocyanide, ferri-cyanide, cobalticyanide, chromate, and dichromate, by ammonium oxalate, molybdate and picrate; by sodium pyrophosphate hydrochloroplatinic acid, mercuric chloride, and stannic chloride. Silver nitrate precipitates only two of the three atoms of contained chlorine, and the subject was studied by O. W. Gibbs and F. A. Genth, R. Lorenz, and P. Job. F. Krauss found that potassium ruthenocyanide gives a crystalline precipitate.

A. Benrath found no sign of the formation of a double salt with potassium chloride when the chloropentamminochloride dissolves in soln. of the alkali chloride, at 25°, when concentrations are expressed in grams per 100 grms. of water :

KCl	.	.	0.00	0.089	0.850	1.093	4.338	6.751	34.460
Co	.	.	0.1337	0.1076	0.0362	0.0161	0.0083	0.0057	0.0007

F. Ephraim and P. Mosimann were unable to prepare double salts of cobaltic chloropentamminochloride with the chlorides of copper, calcium, barium, zinc, cadmium, aluminium, manganese, iron (ic), cobalt, or nickel. O. W. Gibbs reported that a chloroaurate, **gold cobaltic chloropentamminopentachloride**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}(\text{AuCl}_4)$, is formed in dark ruby-red, prismatic crystals by adding auric chloride to a hot, aq. soln. of the chloropentammine. F. Claudet, O. W. Gibbs, and E. Carstanjen reported that with mercuric chloride or sodium mercuric chloride, an aq. soln. of the chloropentamminochloride furnishes **mercuric cobaltic chloropentamminoctochloride**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2 \cdot 3\text{HgCl}_2$, in small, red needles or prisms. A. Benrath observed the formation of this salt in soln. The solubility of the chloropentammine chloride in soln. containing mercuric chloride—when the concentrations are expressed in grms. per 100 grms. of water, at 25°—was :

HgCl ₂	.	0.00	0.1265	0.1680	0.1818	0.228	0.261	0.643	2.33
Co	.	0.1350	0.1525	0.1545	0.1174	0.1148	0.681	0.0514	0.0099

F. Ephraim and P. Mosimann said that the addition of potassium chloride to a soln. of the salt converts it into **mercuric cobaltic chloropentamminotetrachloride**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2 \cdot \text{HgCl}_2$. G. Vortmann and E. Morgulis reported that a double salt is formed with mercuric chloride; and O. W. Gibbs described a salt with 2HgCl_2 , but S. M. Jörgensen could not confirm this. S. M. Jörgensen observed that the salt $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2 \cdot 3\text{HgCl}_2$ is sparingly soluble in cold water, but more soluble in hot water, and it is decomposed into its two components by hydrochloric acid. F. Ephraim said that the sp. gr. of the salt is 3.661 at 25°, and the mol. vol., 290.9. A. Benrath studied the conductivity of aq. soln., and N. R. Dhar found that the mol. conductivity, μ , of soln. of a mol of the salt in v litres, at 30°, is :

v	.	.	.	769.4	1538.8	30,776.6	6155.2	12,310.4
μ	.	.	.	265.42	356.34	405.46	445.75	461.88

A. Hiendlmayr prepared **cobaltic fluopentamminochloride**, $[\text{Co}(\text{NH}_3)_5\text{F}]\text{Cl}_2$, by the action of hydrochloric acid on a soln. of the corresponding fluoride. It is a dark red powder, soluble in water. Boiling water converts it into $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]\text{Cl}_3$. R. Duval prepared **cobaltic formatopentamminochloride**, $[\text{Co}(\text{NH}_3)_5(\text{COOH})]\text{Cl}_2$; and **cobaltic chloropentamminodithionate**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{S}_2\text{O}_6$.

A. Werner,⁶ and A. Werner and V. L. King described the preparation and properties of **cobaltic chlorobisethylenediamineamminochloride**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Cl}]\text{Cl}_2$; and S. M. Jörgensen, of the *dihydrate*. J. Petersen studied the lowering of the f.p. of aq. soln.; A. Gordienko, and J. Angerstein, the absorption spectrum; A. Werner and C. Herty, and J. Petersen, the electrical conductivity of aq. soln.; E. Rosenbohm, L. C. Jackson, and L. A. Welo, the magnetic properties; and A. Werner, and S. M. Jörgensen, the chemical properties. The magnetic properties of an optically-active form, the *lævo*-salt, were studied by S. Rosenbohm, and L. C. Jackson. H. E. Watts prepared **cobaltic chlorobispropylenediamineamminochloride**, $[\text{Co}(\text{NH}_3)_2\text{pn}_2\text{Cl}]\text{Cl}_2$; and E. Berl, **cobaltic chlorobisethylenediaminehydroxylaminechloride**, $[\text{Co}(\text{NH}_2\text{OH})_2\text{en}_2\text{Cl}]\text{Cl}_2$, as well as double salts with gold and platinum chlorides. A. Werner also reported **cobaltic cis-chlorobisethylenediamineamminochloride**; R. Vogel, and R. Plischke prepared **cobaltic chloropyridinebisethylenediaminechloride**,

[Co en₂pyCl]Cl₂, as well as the double salts, zinc cobaltic chloropyridinebisethylenediaminechloride, [Co en₂pyCl]Cl₂.ZnCl₂.H₂O; mercuric cobaltic chloropyridinebisethylenediaminechloride, [Co en₂pyCl]Cl₂.HgCl₂.H₂O; stannous cobaltic chloropyridinebisethylenediaminechloride, [Co en₂pyCl]Cl₂.SnCl₂; and also ferric cobaltic chloropyridinebisethylenediaminechloride; J. Meisenheimer and E. Kiderlen, cobaltic chloroethylaminebisdiethylenediaminechloride, [Co en₂(C₂H₅NH₂)Cl]Cl₂; the *cis*- and *trans*-forms of cobaltic chloroallylaminebisethylenediaminechloride, [Co en₂C₃H₅.NH₂)Cl]Cl₂; cobaltic chloroanilinebisethylenediaminechloride, [Co en₂(C₆H₅.NH₂)Cl]Cl₂; cobaltic chloro-*p*-toluidinebisethylenediaminechloride, [Co en₂(C₇H₇.NH₂)Cl]Cl₂; and cobaltic chlorobenzylaminebisethylenediaminechloride, [Co en₂(C₇H₇.NH₂)Cl]Cl₂.

A. Werner⁷ obtained cobaltic *cis*-chloroaquotetramminochloride, [Co(NH₃)₄(H₂O)Cl]Cl₂, by keeping the diaquotetramminochloride for a long time, and by the hydration of trans-dichlorotetramminochloride; W. Schramm, by the action of malonic acid on the diaquotetramminochloride, or on hydroxyaquotetramminochloride; S. M. Jörgensen, and G. Vortmann and co-workers, by treating the carbonatotetramminochloride with cold, 1:1-hydrochloric acid, and then with the conc. acid; and S. M. Jörgensen, by the action of ice-cold hydrochloric acid on chloroaquotetramminosulphate. The violet powder was found by F. M. Jäger to have rhombic bipyramidal crystals with axial ratios $a:b:c=0.908:1:0.925$, and sp. gr. 1.847 at 20°; the mol. vol., 136.05; and topic axial ratios $\chi:\psi:\omega=4.4067:4.4852:6.8834$. J. D. Dana gave 1.802 for the sp. gr.; E. Birk, and W. Biltz, 1.825 at 25°/4°, and mol. vol. 137.8. H. Skraup and co-workers studied the capillary rise of the aq. soln.; J. Petersen, the lowering of the f.p. of aq. soln.; J. Angerstein, A. Gordienko, Y. Shibata, A. N. Nikolopulos, R. Luther and A. N. Nikolopulos, and K. Matsuno, the absorption spectrum; and J. Petersen, the electrical conductivity of aq. soln. A. Werner and A. Miolati found the mol. conductivity, μ , of soln. with a mol of the salt in v litres, at 25°, to be:

v		128	256	512	1024
μ {	at the start	221.3	253.7	293.7	318.9
	in 5 hrs.	321.3	342.5	363.2	380.6

The maximum attained in 5 hrs. shows that the transformation to the diaquotetramminochloride is complete. J. N. Brönsted studied the rate of the transformation: [Co(NH₃)₄(H₂O)Cl]⁺⁺ + H₂O = [Co(NH₃)₄(H₂O)₂]⁺⁺⁺ + Cl⁻, which is a reaction of the first order at 20°. S. M. Jörgensen observed that at ordinary temp. a gram of the chloroaquotetramminochloride dissolves in about 40 grms. of water; and J. N. Brönsted and A. Petersen, that a sat. soln. at 0° contains 0.057 mol per litre, and at 20°, 0.11 mol. A. Benrath and K. Andreas observed no change in the nature of the solid phase when hydrochloric acid is added to the aq. soln. at 25°, but the solubility of the salt drops from about 1 per cent. of Co in soln. to 0.01 per cent. Co when 28.93 per cent. HCl is present. S. M. Jörgensen observed that the cold, sat. soln. when freshly prepared, gives crystalline precipitates with conc. hydrochloric, dil. nitric or hydrofluosilicic acid, with ammonium sulphate or oxalate, with sodium hydrophosphate, with potassium chromate, hydrochloroplatinic acid, and mercuric chloride, but not with sodium dithionate, or potassium chloroplatinite. W. Schramm observed that oxalic acid forms [Co(NH₃)₄(C₂O₄)]Cl, but malonic acid has very little action. P. Job, and S. M. Jörgensen observed that with freshly-prepared soln., silver nitrate precipitates only two-thirds of the contained chlorine, but all is precipitated with aged soln. where the chloraquotetrammine has passed into diaquotetrammine. Sodium nitrite converts the chloroaquotetrammine into the *cis*-nitro-salt. K. Matsuno studied the flocculation of the hydrosol of arsenic sulphide by this salt. G. Vortmann and co-workers prepared cobaltic chloroaquotetramminooctochloride, [Co(NH₃)₄(H₂O)Cl]Cl₂.3HgCl₂, in small, violet prisms, sparingly soluble in cold water, freely soluble in hot water.

A. Werner prepared cobaltic chloroaquobisethylenediaminechloride, [Co en₂(H₂O)Cl]Cl₂, by hydrating dichlorobisethylenediaminechloride, or, according to W. Schramm, by the

action of malonic acid on that salt; and it is also produced by the action of conc. hydrochloric acid on the corresponding sulphate. The salt was found by A. Werner to be fairly stable in cold, aq. soln., but when heated it produces a complicated mixture of products studied by A. Uspensky and K. Tschibisoff. The absorption spectrum was investigated by C. Schleicher, and A. Uspensky and K. Tschibisoff. J. Meisenheimer and E. Kiderlen studied the reaction with aniline; and F. M. Jäger and P. Koets, the reaction with triaminotriethylamine. H. Fischlin separated the *dextro*-salt and the *laevo*-salt by treating the optically-active bromide of the series with hydrochloric acid. The reddish-black, cubic crystals are freely soluble in water. The sp. rotation of a 0.1 per cent. aq. soln. is 252° for Na-light.

A. Werner prepared **cobaltic chlorodiaquotriamminochloride**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_2\text{Cl}]\text{Cl}_2$, by the action of conc. hydrochloric acid on the violet sulphate. E. Birk found the sp. gr. of the dark violet, crystalline powder to be 1.872 at $25^\circ/4^\circ$, and the mol. vol. 134.9. W. Biltz also studied the contraction which occurs during the formation of the salt.

Basic cobaltic pentammines were studied by O. W. Gibbs and F. A. Genth.⁸ H. Schiff, S. M. Jörgensen, and A. Werner. H. Schiff, and C. D. Braun obtained **cobaltic hydroxypentamminochloride**, $[\text{Co}(\text{NH}_3)_5(\text{OH})]\text{Cl}_2 \cdot \text{H}_2\text{O}$, by treating either the hydroxypentamminosulphate, or aquopentamminochloride, with barium chloride in a feebly ammoniacal soln. P. Job studied its formation from the aquopentammine. A. Werner obtained it by the action of ammonia on the aquopentamminochloride; and G. T. Morgan and J. D. M. Smith, by mixing an ice-cold soln. of 23.8 grms. of hexahydrated cobalt chloride in 15 c.c. of water with 8.5 c.c. of $12\text{N-H}_2\text{O}_2$, and then with 57 c.c. $18\text{N-NH}_4\text{OH}$, added slowly. The evaporation of the liquor furnishes the chloride in purple-red needles; A. Werner obtained the salt in violet-red scales. M. Chatelet-Lavollay, and Y. Shibata and G. Urbain studied the absorption spectrum; and N. R. Dhar and G. Urbain, the polarization tension—*vide supra*, the hexammine. According to A. Werner, the salt forms a bluish-red solution in water; it liberates ammonia from ammonium salts; and according to H. Schiff, warm hydrochloric acid converts it into chloropentamminochloride. J. N. Brönsted studied the catalysis of acids and bases by the salt; and J. N. Brönsted and E. A. Guggenheim, the effect on the mutarotation of glucose.

A. Werner prepared **cobaltic hydroxyaquotetramminochloride**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{OH})]\text{Cl}_2$, by the action of cold, conc., aq. ammonia on the diaquotetramminochloride; and J. V. Dubsy, what he regarded as a *monohydrate*, by the action of aq. ammonia on octamminodiolchloride. The violet-red salt liberates ammonia from ammonium salts; it does not form silver oxide with silver nitrate, showing that the OH-group is part of the inner complex. The compound is not acetylated by the action of acetic anhydride, but it is converted into octamminodiolchloride, and the same transformation occurs when the salt is heated to 100° . The salt is unstable in aq. soln. W. Schramm found that oxalic acid converts it into the oxalatotetrammine, and malonic acid forms the chloroaquo-salt.

M. Rosner prepared **cobaltic hydroxydipyridinetriamminochloride**, $[\text{Co}(\text{NH}_3)_3\text{py}_2(\text{OH})]\text{Cl}_2 \cdot 5\text{H}_2\text{O}$; and A. Werner obtained **cobaltic cis-hydroxyaquobisethylenediaminechloride**, $[\text{Co}(\text{en})_2(\text{H}_2\text{O})(\text{OH})]\text{Cl}_2 \cdot \text{H}_2\text{O}$, by the action of a soln. of pyridine on cis-diaquobisethylenediaminechloride; and J. Meisenheimer and E. Kiderlen, and A. Werner, **cobaltic trans-hydroxyaquobisethylenediaminechloride**, by the action of an aq. soln. of an organic base on trans-diaquobisethylenediaminechloride. A. Werner also obtained it by warming cis-dichlorobisethylenediaminechloride with conc. aq. ammonia. A. Werner prepared **cobaltic hydroxyaquodipyridinediamminochloride**, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{H}_2\text{O})(\text{OH})]\text{Cl}_2$, by treating dichloroaquodipyridinediamminochloride with pyridine and potassium chloride in cold, aq. soln. The salt was also studied by J. Meyer and co-workers. Y. Nakasuka and H. Inuma studied the **cobaltic bisdimethylglyoximediamines**.

The CoA₄ or Tetrammine Family.

E. Böhm⁹ obtained **cobaltic difluotetramminochloride**, $[\text{Co}(\text{NH}_3)_4\text{F}_2]\text{Cl}$, by treating a soln. of carbonatotetramminochloride, in as little water as possible,

with conc. hydrofluoric acid, until the evolution of carbon dioxide had ceased. On standing for some days at room temp., the soln. deposits dark red crystals, fairly stable in air, freely soluble in water. H. Siebt also prepared **cobaltic trans-difluorobisethylenediaminechloride**, $[\text{Co en}_2\text{F}_2]\text{Cl}$, in pale green needles, by treating an ice-cold soln. of the fluoride of the series with ammonium chloride.

A series of cobaltic dichlorotetrammines has been prepared by O. W. Gibbs and F. A. Genth,¹⁰ F. Rose, G. Vortmann, R. Pers, S. M. Jörgensen, and A. Werner and co-workers. A. Werner and A. Klein prepared **cobaltic trans-dichlorotetramminofluoride**, presumably $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{F}$, by treating a conc. soln. of the corresponding sulphate with ammonium or potassium fluoride. Dichroic crystals are precipitated, and they are freely soluble in water.

A. Werner obtained **cobaltic dichlorotetramminochloride**, $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl} \cdot \frac{1}{2}\text{H}_2\text{O}$, by shaking carbonatotetramminochloride at ordinary temp. with twice as much absolute alcohol saturated with hydrogen chloride at 0° , until the evolution of carbon dioxide ceases. The product is washed with absolute alcohol until free from acid; it is also obtained by triturating octamminodiolchloride with saturated hydrochloric acid, and then washing the product with alcohol. W. Schramm prepared the salt, and A. Werner made a product of a high degree of purity as follows:

Two grams of the dithionate of the series were triturated with 4 grms. of ammonium chloride and 4 c.c. of water; the dark blue product was then rubbed up with an excess of ammonium chloride and a little water, dissolved in as little cold water as possible, and ammonium chloride added to the soln. for precipitation. The product was washed with water, and then with alcohol and ether.

The violet prisms and needles lose their water at 60° . The salt is freely soluble in water, forming a blue soln. which rapidly becomes violet or reddish-violet as the dichlorotetrammine passes into the aquo-salt. A. N. Nikolopulos, and R. Luther and A. N. Nikolopulos studied the absorption spectrum of the soln. K. Andréas studied the systems: $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}-\text{HCl}-\text{H}_2\text{O}$, at 25° , and also $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}-\text{NH}_3-\text{H}_2\text{O}$, at 25° . A. Werner noted that a freshly-prepared aq. soln. precipitates the corresponding salt of the series when treated with dil. sulphuric acid, conc. nitric acid, ammonium bromide, sulphate, nitrate, or thiocyanate, or sodium dithionate; potassium chloroplatinite gives a bluish-violet precipitate, that with hydrochloroplatinic acid is greyish-green, and that with potassium dichromate, bronze, and potassium chromate, greyish-brown. No precipitation occurs with sodium nitrite, potassium chlorate or cyanide, or with ammonium oxalate.

O. W. Gibbs and F. A. Genth, F. Rose, and G. Vortmann obtained the corresponding **cobaltic trans-dichlorotetramminochloride**, $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl} \cdot \text{H}_2\text{O}$; and S. M. Jörgensen recommended preparing it by mixing 10 grms. of powdered chloro-aquotetramminochloride (or diaquotetramminosulphate) with 50 c.c. of conc. sulphuric acid, and after some hours, adding to the ice-cold liquid, 50 c.c. of conc. hydrochloric acid. After the mixture has stood some hours, it begins to crystallize. In two days, the crystals are washed with dil. sulphuric acid, then with dil. hydrochloric acid until free from sulphuric acid, and then with alcohol until free from acid. A. Uspensky and K. Tschibisoff studied the stereoisomerides of the tetrammines. The green crystals of the monohydrate were found by F. Ephraim and O. Schütz to have a sp. gr. of 1.844 at 25° , and a mol. vol. of 136.5, and the anhydrous salt a sp. gr. of 1.799 at 25° , and a mol. vol. of 129.8. E. Birk gave 1.860 for the sp. gr. of the anhydrous salt, and 125.5 for the mol. vol. H. Skraup and co-workers measured the capillary rise of the aq. soln. E. Petersen measured the lowering of the f.p. of aq. soln. A. N. Nikolopulos, and R. Luther and A. N. Nikolopulos, the absorption spectrum; and O. Stelling, and S. Aoyama and co-workers, the X-ray spectrum. E. Petersen found the mol. conductivity, μ , of a soln. with a mol of the salt in v litres, to be:

v	25	50	100	200	1600	3200
$\mu \left\{ \begin{array}{l} 0^\circ \\ 25^\circ \end{array} \right.$	94.0	106.0	115.1	128.1	143.2	156.1
	—	193.1	245.7	287.4	376.8	391.8

The values increase with time, owing to the hydrolysis of the salt. The data were discussed by A. Werner and C. Herty, and W. D. Harkins and co-workers. The aquation of the salt in aq. soln.: $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl} \rightarrow [\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Cl}]\text{Cl}_2 \rightarrow [\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]\text{Cl}_3$, was found by K. Matsuno to be a unimolecular reaction. The first reaction occupies 30 minutes under conditions where the second one occupies 24 hrs. R. Schwarz and K. Tede studied the photolysis of the soln. in ultra-violet light. N. R. Dhar and G. Urbain studied the polarization tension. E. Rosenbohm gave -2.24×10^{-6} mass unit for the magnetic susceptibility of the salt; and the magnetic properties were studied by E. Feytis, W. Biltz, and L. C. Jackson. J. N. Brönsted and A. Petersen found that the sat. aq. soln. at 0° contains 0.0141 mol per litre; and A. Werner and P. Larisch, 0.366 gm. per 100 grms. of water at 0° . The solid phase in hydrochloric acid is not stable at 25° , but forms the chloroaquatetramminochloride; the solubility of the salt falls from 0.98 per cent. Co to 0.01 per cent. Co in the presence of 29.07 per cent. HCl. Silver nitrate was found by A. Werner to give a precipitate with the aq. soln., probably a double salt. A. Werner and A. Klein found that with auric chloride, green crystals of **gold cobaltic dichlorotetramminotetrachloride**, $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{AuCl}_4$, are formed; and with a mercuric chloride, a green crystalline precipitate of **mercuric cobaltic dichlorotetramminotetrachloride**, $2[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}.\text{HgCl}_2$, was prepared by A. Werner and A. Klein, and G. Vortmann. The latter also obtained **mercuric cobaltic dichlorotetramminotrichloride**, $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}.\text{HgCl}_2$. E. Böhm prepared **cobaltic difluorotetramminochloride**, $[\text{Co}(\text{NH}_3)_4\text{F}_2]\text{Cl}$, by dissolving carbonatotetramminochloride in the smallest possible quantity of water, and treating the soln. with hydrofluoric acid until the evolution of carbon dioxide ceases. Dark red crystals separate from the liquid in a few days when kept at room temp. The crystals are fairly stable in air, and freely soluble in water. H. Seibt also prepared **cobaltic trans-difluorobisethylene-diaminochloride**, $[\text{Co en}_2\text{F}_2]\text{Cl}$, by the action of ammonium chloride on a cold soln. of the fluoride.

A. Werner and R. Feenstra,¹¹ and T. S. Price prepared **cobaltic trans-dichlorotetrapyridinechloride**, $[\text{Co py}_4\text{Cl}_2]\text{Cl}.\text{H}_2\text{O}$, in green plates found by R. Lorenz and I. Posen, and I. Posen to have a sp. gr. of 1.3990; the salt dehydrated at 61° has a sp. gr. 1.461. The eq. conductivity, and the transport number of the anion were measured by R. Lorenz and I. Posen, and the chemical properties were studied by A. Werner and R. Feenstra, and T. S. Price. A. Werner and R. Feenstra reported **gold cobaltic dichlorotetrapyridinetetrachloride**, $[\text{Co py}_4\text{Cl}_2](\text{AuCl}_4)$; and T. S. Price, **mercuric cobaltic dichlorotetrapyridinedodecachloride**, $2[\text{Co py}_4\text{Cl}_2]\text{Cl}.\text{3HgCl}_2$.

A. Werner, R. Plischke, R. Vogel, A. Uspensky and K. Tschibisoff, and S. M. Jörgensen obtained **cobaltic cis-dichlorobisethylenediaminechloride**, $[\text{Co en}_2\text{Cl}_2]\text{Cl}.\text{H}_2\text{O}$, in dark violet crystals requiring about 25 grms. of water to dissolve a gram of salt. The constitution of the salts of this series was discussed by A. Werner, S. M. Jörgensen, J. A. N. Friend, and E. E. Turner. K. Andreas studied the action of hydrochloric acid, and of aq. ammonia on the salt. J. Petersen studied the lowering of the f.p. of water; A. Uspensky and co-workers, J. Lifschitz and E. Rosenbohm, R. Samuel, M. L. Ernsberger and W. R. Brode, W. Kuhn and K. Bein, and C. Schleicher, the absorption spectrum; O. Stelling, the X-ray spectrum; A. Werner and C. Herty, L. Tschugaeff, W. D. Harkins and co-workers, and J. Petersen, the electrical conductivity; E. Rosenbohm, L. C. Jackson, and W. Biltz, the mechanical properties; and S. M. Jörgensen, A. Werner and co-workers, T. S. Price and S. A. Brazier, A. Uspensky and K. Tschibisoff, K. Matsuno, and J. Meisenheimer and K. Kiderlen, the chemical properties. A. Werner and co-workers prepared optically-active forms, where the sp. rotation of a 0.25 per cent. aq. soln. of the *dextro*-salt was 184° , and of the *levo*-salt, -200° . S. M. Jörgensen prepared violet scales of **mercuric cobaltic dichlorobisethylenediaminetrichloride**, $[\text{Co en}_2\text{Cl}_2]\text{Cl}.\text{HgCl}_2$. S. M. Jörgensen, H. Schwarz, H. Siebt, E. Schmidt, K. R. Lange, W. A. Redeker, and A. Werner prepared **cobaltic trans-dichlorobisethylenediaminechloride**, $[\text{Co en}_2\text{Cl}_2]\text{Cl}$, in emerald green, prismatic crystals. A. Werner and C. Herty, and J. Petersen measured the lowering of the f.p. in aq. soln.: C. Schleicher, A. Gordienko, Y. Shibata, Y. Shibata and G. Urbain, A. Uspensky and K. Tschibisoff, M. L. Ernsberger and W. R. Brode, and J. Lifschitz and E. Rosenbohm, the absorption spectrum; A. Werner and C. Herty, and L. Tschugaeff, the electrical conductivity; and S. Berkman and H. Zocher, the magnetic susceptibility. The aquation of the salt in aq. soln.: $[\text{Co en}_2\text{Cl}_2]\text{Cl} \rightarrow [\text{Co en}_2(\text{H}_2\text{O})\text{Cl}]\text{Cl}_2 \rightarrow [\text{Co en}_2(\text{H}_2\text{O})_2]\text{Cl}_3$, was studied by A. Uspensky and K. Tschibisoff.

bisoff, Y. Shibata, A. Werner, S. M. Jörgensen, K. Matsuno, and A. Benrath and K. Andreas. The chemical properties were studied by A. Werner and co-workers, S. M. Jörgensen, J. Meisenheimer and E. Kiderlen, and W. Schramm. T. S. Price and S. A. Brazier noted the formation of addition products with lactic acid, and malonic acid. S. M. Jörgensen, A. Werner and co-workers, P. Pfeiffer and co-workers prepared **cobaltic trans-dichlorobisethylenediaminehydrochloride**, $[\text{Co en}_2\text{Cl}_2]\text{Cl} \cdot \text{HCl} \cdot 2\text{H}_2\text{O}$, and the properties of the compound were studied by A. Werner, S. M. Jörgensen, T. S. Price and S. A. Brazier, S. Berkman and H. Zocher, and A. Uspensky and K. Tschibisoff. P. Pfeiffer and M. Tapuach prepared **antimony cobaltic dichlorobisethylenediaminehexachloride**, $[\text{Co en}_2\text{Cl}_2]\text{SbCl}_6$; and S. M. Jörgensen, mercuric cobaltic trans-dichlorobisethylenediamine-trichloride, $[\text{Co en}_2\text{Cl}_2]\text{Cl} \cdot \text{HgCl}_2$. G. and P. Spacu prepared copper cobaltic dichlorobisethylenediaminechloride, $[\text{Co en}_2\text{Cl}_2]_2\text{CuCl}_4$; cadmium cobaltic dichlorobisethylenediaminechloride, $[\text{Co en}_2\text{Cl}_2]_2\text{CdCl}_4$; stannous cobaltic dichlorobisethylenediaminechloride, $[\text{Co en}_2\text{Cl}_2]_2\text{SnCl}_3$; stannic cobaltic dichlorobisethylenediaminechloride, $[\text{Co en}_2\text{Cl}_2]_2\text{SnCl}_6$; bismuth cobaltic dichlorobisethylenediaminechloride, $[\text{Co en}_2\text{Cl}_2]_2\text{BiCl}_6$.

H. E. Watts, and A. Werner and A. Fröhlich obtained **cobaltic cis-dichlorobispropylenediaminechloride**, $[\text{Co pn}_2\text{Cl}_2]\text{Cl}$, in violet crystals, and **cobaltic trans-dichlorobispropylenediaminechloride**, $[\text{Co pn}_2\text{Cl}_2]\text{Cl}$, in pale green plates, and the salt was also examined by A. Werner, and W. Schramm. A. Werner and A. Fröhlich obtained **cobaltic dichlorobispropylenediaminehydrochloride**, $[\text{Co pn}_2\text{Cl}_2]\text{Cl} \cdot \text{HCl} \cdot 2\text{H}_2\text{O}$; and they also prepared **gold cobaltic dichlorobispropylenediaminetetrachloride**, $[\text{Co pn}_2\text{Cl}_2]\text{AuCl}_4$; and mercuric cobaltic dichlorobispropylenediamineheptachloride, $3[\text{Co pn}_2\text{Cl}_2]\text{Cl} \cdot 2\text{HgCl}_2$. A. Werner and G. Lindenberg prepared **cobaltic trans-dichlorotrimethylenediaminechloride**, $[\text{Co}(\text{C}_3\text{H}_{10}\text{N}_2)_2\text{Cl}_2]\text{Cl}$, in green, prismatic crystals; F. M. Jäger and H. B. Blumendal **cobaltic cis-dichlorobiscyclopentanediaminechloride**, $[\text{Co}(\text{C}_5\text{H}_{12}\text{N}_2)_2\text{Cl}_2]\text{Cl}$, and also **cobaltic trans-dichlorobiscyclopentanediaminechloride**; A. Werner prepared **cobaltic dichlorobispyridinediaminediaminochloride**, $[\text{Co}(\text{NH}_3)_2\text{py}_2\text{Cl}_2]\text{Cl}$, as a green, crystalline powder; A. Werner and F. Chaussey, and C. Rix, **cobaltic trans-dichloroethylenediaminediaminochloride**, $[\text{Co}(\text{NH}_3)_2\text{enCl}_2]\text{Cl}$, in green crystals; and C. J. Dippel and F. M. Jäger, **cobaltic dichlorobisdiaminopentanochloride**, $[\text{Co ptn}_2\text{Cl}_2]\text{Cl}$, with $\alpha\beta\delta$ - and $\beta\beta\delta$ -aminopentane; and E. N. Gapon, **cobaltic dichlorobisphenylethylenediaminochloride**, $[\text{Co}(\text{CH}_2 \cdot \text{NH}_2 \cdot \text{C}_6\text{H}_5)_2\text{Cl}_2]\text{Cl}$ —cis- and trans-forms.

P. Job observed that when alkali hydroxide is added gradually to a soln. of cobaltic diaquotetramminochloride (or sulphate), the measurements of the e.m.f. show that no hydroxyl ions are present until more than 2 eq. of alkali have been added. The soln. contains **cobaltic dihydroxytetramminochloride**: $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]\text{Cl}_3 + 2\text{KOH} = [\text{Co}(\text{NH}_3)_4(\text{OH})_2]\text{Cl} + 2\text{KCl} + 2\text{H}_2\text{O}$. H. J. S. King found that the electrical conductivity, λ , at 0° , of soln. with a mol of the dihydroxytetrammine, in v litres, is:

v	.	.	33.98	67.96	79.94	159.9	261.4	524.4	1036
λ	.	.	52.25	55.08	55.71	57.72	59.32	61.16	69.60

The mobility of the ion is 23.0, and $n=1.50$.

In 1871, F. Rose¹² reported greyish-green **cobaltic dichloroaquotriamminochloride**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{Cl}_2]\text{Cl}$, to be formed when an ammoniacal soln. of cobaltous chloride is oxidized until cobaltic hydroxide begins to separate, and then mixed with an excess of hydrochloric acid and allowed to crystallize. S. M. Jörgensen observed that the same salt is produced when the acid sulphate of the series is treated with 1:1 hydrochloric acid; and when a soln. of cobaltic trinitratotriammine is treated with dil. hydrochloric acid, allowed to stand 24 hrs., and then treated with conc. acid. J. Meyer and co-workers employed a somewhat similar process for the greyish-green salt. S. M. Jörgensen, and J. N. Brönsted and K. Volquartz said that the compound appears in two forms: (1) By precipitation from the soln. by the addition of some drops of hydrochloric acid to a soln. of the chloride in conc. hydrochloric acid, the salt is obtained in black, stable crystals which are dichroic—pale red and dark green. (2) By adding 2 vols. of conc. hydrochloric acid to 1 vol. of an aq. soln. of the chloride, thin, hexagonal plates are produced, and they are unstable, and not dichroic. A. Werner prepared a grey form of the salt by rubbing up chlorodiaquotriamminosulphate with conc. hydrochloric acid, pressing the product between porous tiles, and washing with alcohol until free from acid. A. Werner said that the two products are not the same; and K. Matsuno guessed that the greyish-green form is the *trans-salt*, and the grey form, the *cis-salt*.

E. Birk gave 1.908 for the sp. gr. of the greyish-green crystals at $25^{\circ}/4^{\circ}$, and 122.9 for the mol. vol. S. M. Jörgensen found that the dry salt is slowly decomposed when it is heated. The absorption spectrum was studied by K. Matsuno; and the X-ray spectrum, by O. Stelling. K. Matsuno showed that the salt is partly hydrolyzed in aq. soln.; and A. Werner and co-workers found that the electrical conductivity in aq. soln. rapidly increases. The conductivity of a mol of the salt in 100 litres at 0° , changed in 250 seconds from 81.32 to 148.51. S. M. Jörgensen also found that the salt is very unstable in aq. soln., and silver nitrate precipitates all the chlorine from the freshly-prepared soln. Conc. sulphuric acid acts on the solid with the evolution of hydrogen chloride. A soln. of sodium chloroplatinate precipitates $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_3]_2(\text{PtCl}_6)_3 \cdot 4\text{H}_2\text{O}$. Phosphoric acid precipitates cobaltous phosphate. R. Klement studied this subject. S. M. Jörgensen observed that oxalic acid precipitates indigo-blue chloro-oxalatotriammine. H. Kaneko studied the effect of the salt on the viscosity of aq. soln. of albumin.

A. Werner and A. Grün, W. Tupizina, and A. Werner and F. Chaussy prepared **cobaltic trans-dichloroquoethylenediammineamminochloride**, $[\text{Co}(\text{NH}_3)_n(\text{H}_2\text{O})\text{Cl}_2]\text{Cl}$, by rubbing up trinitratoethylenediammine with conc. hydrochloric acid whilst the mixture is being heated on a water-bath; dissolving the product in the smallest amount of water possible, and adding hydrochloric acid. The small, greenish-black needles so obtained are feebly dichroic.

A. Werner prepared blue **cobaltic dichlorodiaquodiamminochloride**, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_2\text{Cl}_2]\text{Cl}$, by triturating chlorotriaquodiamminosulphate with conc. hydrochloric acid, and pressing the product between porous tiles. The green powder is freely soluble in water, forming a blue soln. What is apparently an isomeric form appears in pale green, dichroic needles, which furnish an emerald-green, aq. soln. which in a few seconds becomes indigo-blue, then violet, and finally red. This variety was obtained by A. Werner, A. Werner and R. Feenstra, S. M. Jörgensen, and E. H. Riesenfeld and R. Klement, by treating potassium tetranitrodiamminocobaltate with conc. sulphuric acid, and slowly adding hydrochloric acid; or by treating the ammonium salt with hydrochloric acid and passing hydrogen chloride through the ice-cold liquid. A. Werner obtained it by adding ice-cold, conc. hydrochloric acid slowly to the sulphate of the series. The acidic soln. furnishes the moss-green crystals, and neutral soln., pale green crystals. The aq. soln. is emerald green. The conductivity measurements of A. Werner and A. Miolati show that the salt in soln. passes into the tetraquo-salt. N. R. Dhar and G. Urbain measured the polarization tension—*vide supra*, the hexammine. The salt is decomposed by phosphoric acid, and R. Klement studied the action of phosphates on the salt.

J. Meisenheimer and E. Kiderlen ¹³ prepared **cobaltic chlorohydroxybisethylenediamminechloride**, $[\text{Co en}_2(\text{OH})\text{Cl}_2]\text{Cl} \cdot \text{H}_2\text{O}$, by rubbing up trans-dichlorobisethylenediamminechloride with a soln. of diethylamine in iced-water so that only partial solution occurs. The crystalline mush is drained by suction, washed with 70 per cent. alcohol, and finally with ordinary alcohol and ether. The compound is also obtained by shaking an aq. soln. of the praseo-chloride with methylbenzylamine. The dove-grey crystals are freely soluble in water, forming a carmine-red soln., and in dil. hydrochloric acid, forming a green soln. The water is lost at 80° in vacuo, and a structural change simultaneously occurs. When the aq. soln. is warmed, it forms the hydroxyaquochloride, which is precipitated by alcohol; and the dissolution of the salt in 15 per cent. hydrochloric acid, and precipitation with alcohol and ether furnishes the greyish-green chloro-aquochloride. The salt was studied by J. C. Bailar and R. W. Auten.

T. S. Price and S. A. Brazier obtained **cobaltic sulphodiacetabisethylenediamminechloride**, $[\text{Co en}_2(\text{C}_2\text{H}_4\text{O}_2\text{S})]\text{Cl} \cdot \text{H}_2\text{O}$, in small, rose-red plates; freely soluble in water; and decomposed at 115° ; a sienna-brown gold **cobaltic sulphodiacetabisethylenediamminechloride**, $[\text{Co en}_2(\text{C}_2\text{H}_4\text{O}_2\text{S})]\text{AuCl}_4$.

The CoA_3 or Triammine Family.

A. Werner and E. Bindschedler ¹⁴ prepared **cobaltic trichlorotriammine**, $[\text{Co}(\text{NH}_3)_3\text{Cl}_3]$, by rubbing up 10 grms. of hexamminetriolchloride with 30 c.c. of cold, conc. hydrochloric acid, and extracting the violet crystalline mush with cold

water until a bluish-green residue is formed. This was washed with alcohol and ether, and dried over sulphuric acid. E. Birk said that the yield is increased by working, at as low a temp. as possible, with saturated hydrochloric acid. The sp. gr. is 1.932 at 25°/4°, and the mol. vol. is 112.0. O. Stelling studied the X-ray spectrum. A. Werner and E. Bindschedler observed that the salt is sparingly soluble in cold water. The aq. soln. is aquated when allowed to stand a long time, or when heated. Conc. hydrochloric acid forms dichloroaquotriamminochloride; but conc. nitric acid has no action. The constitution was discussed by E. Gapon, J. A. N. Friend, and E. E. Turner.

The Peroxo-Salts.

F. Rose¹⁵ said that a *schwarze Salz* is produced along with other chlorides when ammoniacal soln. of cobalt salts are oxidized by air for not too long a time, and in the cold, and it is very sparingly soluble in dil. hydrochloric acid. Translating his equivalent formula, his analysis gave him $\text{Co}_9\text{Cl}_{22}\text{ON}_{32}\text{H}_{90}$ to 92. O. W. Gibbs represented F. Rose's data by the simpler formula: $\text{Co}_2(\text{NH}_3)_6\text{OCl}_4\cdot\text{NH}_4\text{Cl}$, but the idea that the product is a complex salt is not in accord with its behaviour. The salt had been previously observed by E. Frémy. G. Vortmann suggested the formula: $\text{Co}_2(\text{NH}_3)_6\cdot\text{Cl}_4\text{NH}_4\text{Cl}$, and designated the product **cobaltic melanochloride**, —μέλας, black. The products so far prepared were shown by A. Werner to be mixtures of a sparingly soluble, dark grey salt, **cobaltic dichloro-μ-amino-peroxo-hexamminochloride** :

and the sparingly soluble melanochloride which he considered to be **cobaltic trichloroaquo-μ-amino-hexamminochloride** :

When an amine or NH_2 -group in a salt is associated with two metal atoms, A. Werner called it a *μ-amino-salt*; when in the salt an imine or NH -group is similarly associated, a *μ-imino-salt*; when in the salt an OH -group is similarly associated, an *ol-salt*; and when in the salt an O_2 -group is similarly associated, a *peroxo-salt*—if the O_2 -group is not so bridged, it is called an *ozo-salt*, just as an unbridged OH -group is called a *hydroxy-salt*. A. Werner recommended preparing cobaltic melanochloride as follows :

A mixture of 650 grms. of cobalt chloride with 400 c.c. of water and 2 litres of 25 per cent. ammonia is heated to boiling, filtered from the precipitated cobalt oxide, and exposed to the air for 48 hours. The resulting brownish-red solution is filtered from the crystals which have deposited, and mixed with 3 litres of concentrated hydrochloric acid. The resulting brownish-red precipitate is quickly collected and extracted with cold water until it becomes pure grey in colour and the wash water is coloured a brownish-violet. One gram of cobalt chloride gives about 60 grms. of melanochloride.

When the grey mixture is treated with a hot soln. of silver nitrate, containing nitric acid, the filtrate, on cooling, deposits dark red crystals of the melanonitrate, and the mother-liquor gives a dark green nitrate which crystallizes out in large leaflets. If in preparing the melanochloride the temp. is kept below 5°, other products are formed in addition to those just indicated—*vide infra*.

The first products of the oxidation of ammoniacal soln. of cobaltous salts by air, described by E. Frémy, and O. W. Gibbs as *oxycobaltiac salts*, were studied by G. Vortmann, A. Mylius, and by A. Werner and co-workers. According to E. Frémy, if the ammoniacal soln. be saturated with ammonium chloride, or,

according to G. Vortmann, if it be treated with alcohol, a brownish-black precipitate is obtained consisting of greenish-brown iridescent plates of **cobaltic peroxo-decamminotetrachloride**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5]\text{Cl}_4$. G. Vortmann noted that the dry salt or the aq. soln. is very unstable, and E. Frémy, that the crystals in contact with water give off oxygen. In this compound both the cobalt atoms are tervalent. If this salt be treated with hydrochloric acid, there is formed **cobaltic peroxo-decamminopentachloride**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_2]\text{Cl}_5$, in which one of the cobalt atoms is quadrivalent, and the other one, tervalent. The exact nature of the salts with the O_2 -linkage is yet unknown, since, amongst the possibilities, are the groups $\text{Co}.\text{O}.\text{O}.\text{Co}$, or:

The green, needle-like crystals are stable in air, but decompose at 110° . The salt was first obtained by L. Maquenne—*vide infra*, for the sulphate. G. Vortmann, and A. Werner and A. Mylius also prepared the salt. The aq. soln. of the salt is unstable. Boiling hydrochloric acid, and a reducing agent, converts it into the chloropentammine and a cobaltous salt; and ammonia convert it into chloropentammine and the hexammine. G. Vortmann obtained **mercuric cobaltic- μ -peroxo-decamminohenachloride**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5]\text{Cl}_5.3\text{HgCl}_2$. According to A. Werner, if a soln. of the aquohydroxy-peroxo-ol-hexamminonitrate, or the corresponding sulphate, in water acidulated with acetic acid, be treated with a little conc. hydrochloric acid, small, greyish-black crystals of **cobaltic trichlorohydroxy-peroxo-hexamminochloride**, $[\text{Cl}_2(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5(\text{OH})\text{Cl}]\text{Cl}$, are formed. They are almost insoluble in water, and the salt is broken down when treated with liquid ammonia.

A. Werner and co-workers prepared what they called **cobaltic diozo-tri-imidodecammino-chloride**, $(\text{O}_2)_2(\text{NH}_3)_3\text{Co}_4(\text{NH}_3)_{10}\text{Cl}_8.2\text{H}_2\text{O}$, by dissolving oxycobaltamine nitrate (300 grms.) in water (2 litres) at 50° , and, after filtration, diluting with an equal bulk of water, adding 4 litres of conc. hydrochloric acid, and then passing a current of air through the soln. for some hours. The black, crystalline precipitate of the crude chloride mixed with imido-hexammine chloride, after washing with alcohol and ether, is converted into the nitrate and re-converted into the chloride. It is a black, crystalline powder, sparingly soluble in cold water, more easily in warm water, is partially decomposed when heated with water at 60° to 70° , completely so when boiled, and gives brown, flocculent precipitates with platinic chloride and mercuric chloride. It is not decomposed by dil. acids or by conc. hydrochloric acid. The constitution of the diozo-salts is unknown. A. Werner and co-workers said that they probably have a constitution similar to that of the peroxo-salts. A comparison of their composition shows that they are formed by the combination of 2 mols. of the ozo-salt with elimination of 1 mol. of ammonia and the addition of 1 mol. of water. In the diozo-series, three imido-groups are present, and, considering the decomposition products obtained from the diozo-salts by the action of sulphurous, nitric, and nitrous acids, it is most probable that their constitution is expressed by a formula indicating the linking of 2 mols. of a peroxo-salt by an imido-group; thus, in the case of the nitrate:

The μ -Amino-Salts.

A. Werner,¹⁶ and P. Wüst treated an aq. soln. of cobaltic aminohexamminopentammine with ammonium chloride, and crystallized **cobaltic- μ -amino-decamminopentachloride**, $[(\text{NH}_3)_5\text{Co}-\text{NH}_2\cdots\text{Co}(\text{NH}_3)_5]\text{Cl}_5$, from the liquid feebly acidified with hydrochloric acid. The reddish-violet needles are soluble in water—at room temp. no part of the salt dissolves in about 80 parts of water. The salt

is stable at 85°, and is not decomposed by boiling water, but with hot, sulphuric or hydrochloric acids, it is resolved into the chloropentammine and the hexammine.

When an ammoniacal soln. of cobaltic nitrate is oxidized by a slow current of air, and then treated with an excess of sulphuric acid, an insoluble sulphate separates out. This has been called *Vortmann's fuscousulphate*, or *cobaltic fuscousulphate*—*fuscus*, dark—and it is one of a series of salts studied by E. Frémy, I. Fürstenberg, C. Schwenk, S. M. Jörgensen, M. Pieper, and G. Vortmann and O. Blasberg.

A. Werner showed that this product is not homogeneous, and by treatment with conc. hydrochloric acid, it furnishes a green, soluble salt, and a red salt which is sparingly soluble. The fuscousulphate can also be converted into nitrate, when the green salt is freely soluble in water, and the red salt is not so soluble. The fuscousulphate thus contains green **cobaltic- μ -amino-peroxo-octamminosulphate**, and red **cobaltic- μ -amino-ol-octamminosulphate** :

A. Werner and F. Salzer observed that if 10 grms. of this crude, red salt, covered with hydrochloric acid of sp. gr. 1.9, are kept at room temp., and the mixture is well-shaken at intervals, the salt passes into soln., the OH-bridge is destroyed, and brownish-violet, acicular crystals of **cobaltic chloroaquo- μ -amino-octamminochloride**, $[(\text{H}_2\text{O})(\text{NH}_3)_4\text{Co}-\text{NH}_2\cdots\text{Co}(\text{NH}_3)_4\text{Cl}]\text{Cl}_4 \cdot 4\text{H}_2\text{O}$, are formed. After 24 hrs., the crystals are collected, dissolved in cold water, and re-precipitated by hydrochloric acid. The salt is freely soluble in water; the soln. has an acidic reaction; and after standing some time, deposits the μ -amino-ol-octamminochloride. When the soln. is boiled with hydrochloric acid, it forms pentammine and tetrammine salts. The freshly-prepared soln. gives characteristic precipitates with hydrochloroplatinic acid, mercuric chloride, and potassium iodide. The salt was studied by C. Schwenk, and A. Baselli. Y. Shibata investigated the absorption spectrum; and K. Matsuno, the action on the hydrosol of arsenic sulphide.

The structure of a number of cobaltammines has not yet been elucidated. There is the *cobaltic fuscocl chloride*—the *dihydrated cobaltic dihydroxyoctamminotetrachloride*, $\text{Co}_2(\text{NH}_3)_8(\text{OH})_2\text{Cl}_4 \cdot 2\text{H}_2\text{O}$, of E. Frémy, C. D. Braun, and G. Vortmann; and the *fuscocl chloride*—*pentahydrated cobaltic trioxo-octamminodichloride*, $\text{Co}_2(\text{NH}_3)_8\text{O}_3\text{Cl}_2 \cdot 5\text{H}_2\text{O}$, of E. Frémy.

Cobaltic melanochloride was found by A. Werner, and A. Werner and F. Steinitzer, to furnish **cobaltic tetrachloro- μ -aminohexamminochloride**, $[\text{Cl}_2(\text{NH}_3)_3\text{Co}-\text{NH}_2\cdots\text{Co}(\text{NH}_3)_3\text{Cl}_2]\text{Cl}$, when dried at 60° to 65°; whereas if dried at the ordinary temp., it is **cobaltic trichloroaquo- μ -amino-hexamminodichloride**, $[\text{Cl}_2(\text{NH}_3)_3\text{Co}-\text{NH}_2\cdots\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{Cl}_2]\text{Cl}_2$. The crystals are violet-black, hexagonal plates; sparingly soluble in water, forming first a brown and then a red soln. The salt decomposes when heated with water; and silver nitrate converts it into diaquo- μ -amino-ol-hexamminonitrate :

According to A. Werner and F. Beddow, when a gram of Vortmann's salt is triturated with 6 to 8 c.c. of conc. hydrochloric acid, it forms a dark green mass which, dissolved in the smallest possible quantity of water, and filtered into conc. hydrochloric acid, yields **cobaltic μ -amino-peroxo-octamminochloride** :

According to A. Werner and F. Beddow, and A. Werner and A. Grün, the dark green prisms are easily soluble in water; the aq. soln. has a neutral reaction, and it soon becomes acidic. The change is not so rapid in acidified soln. The 1 per cent. aq. soln. gives precipitates with sodium sulphate and phosphate, with potassium dichromate, chloroplatinite, and ferrocyanide, and with hydrochloroplatinic acid, but not with potassium iodide, cyanide, ferriyanide, and chloroaurate. A. Werner, and P. Wüst found that the central μ -amino-peroxo-group is very stable, and when the nitrate is warmed with 10 per cent. ethylenediamine all the ammonia can be replaced by ethylenediamine. If the resulting solution is then neutralized with nitric acid at the ordinary temp., a green salt is obtained; when the neutralization is carried out at low temp., a red salt is obtained. These salts only differ in their molecular composition, in that the former is anhydrous, whereas the latter contains 2 mols. of water of crystallization. The aq. soln. of the former is neutral, whereas that of the latter is acid. On warming a nitric acid soln. of the red salt, it changes into the green salt. The green salt is cobaltic μ -amino-peroxo-quaterethylenediaminenitrate; during its preparation some decomposition occurs, and trisethylenediamine salts are formed. If the green salt is treated with potassium bromide, the corresponding bromide is produced, and if the bromide is treated with silver chloride, a soln. is produced which, when evaporated on the water-bath, furnishes dark green, cubic crystals of **cobaltic μ -amino-peroxo-quaterethylenediaminechloride**:

The salt is freely soluble in water, so that it cannot be separated from its aq. soln. by precipitation processes. The salt, over calcium chloride, decomposes with the loss of a mol. of water, and it loses all its water in the drying oven. If the groups ($\text{en}_2\text{Co}^{\text{III}}$) and ($\text{en}_2\text{Co}^{\text{IV}}$) be called A and B, it follows that four optically-active isomerides are theoretically possible—viz., $+A+B$, $-A-B$, and $-A+B$.

As first indicated, in connection with the preparation of cobaltic μ -amino-peroxo-quaterethylenediaminenitrate, A. Werner showed that when the red salt is neutralized with nitric acid at a low temp., a red salt is obtained, which can be converted into the bromide, and, presumably, also into **cobaltic μ -iminohydrochloro-peroxo-quaterethylenediaminechloride**:

When the red and green salts are digested with ammonia, the mol. of acid is given off in the complex, and if the nitrate is triturated with a mixture of ammonia and sodium iodide, an iodide is formed, and when the aq. soln. of the iodide is shaken with silver chloride, **cobaltic μ -imino-peroxo-quaterethylenediaminechloride** is formed:

Crystals of the chloride could not be obtained by evaporating the soln. The addition of potassium chloroplatinite to the aq. soln. gives a brownish-red precipitate of a double salt; and likewise with potassium chloraurate. The addition of hydrobromic acid and ammonium bromide produces the μ -ammonium-peroxo-quaterethylenediaminebromide. If hydrochloric acid be added to the soln. of the chloride, it becomes red, owing to the formation of the ammonium-peroxo-salt, and then green, owing to its conversion to the isomeric amino-peroxo-salt.

A. Werner and R. Feenstra prepared **cobaltic iminobispyridineoctamminotetrachloride**, $[(\text{NH}_3)_4\text{pyCo.NH.Co}(\text{NH}_3)_4\text{py}] \text{Cl}_4$, by warming cobaltic dichloro-aquotriamminochloride with water and pyridine. The yield is small. Conc. hydrobromic acid converts it into the bromide; it is easily soluble in water; and is precipitated from the soln. in golden-yellow needles by conc. hydrochloric acid. A. Werner is not satisfied with this formulation of the constitution.

According to A. Werner, when an aq. soln. of cobaltic μ -amino-ol-peroxo-hexamminochloride is warmed with conc. hydrochloric acid; or when a cold, conc. soln. of the corresponding nitrate is treated with conc. hydrochloric acid; or when an aq. soln. of μ -amino-peroxo-octammino-salt is treated with ammonium chloride, and then saturated with hydrogen chloride, black crystals of symmetrical **cobaltic dichloro- μ -amino-peroxo-hexamminochloride** are formed. When a soln. of μ -amino-peroxo-octamminonitrate is treated with an excess of ammonium carbonate instead of chloride, and hydrochloric acid is added to the cold liquid, dark olive-green crystals of an isomeric-form, namely, the asymmetrical salt, are found:

The asymmetrical salt is readily soluble in water, whereas the symmetrical salt is sparingly soluble. The action of liquid ammonia on the symmetrical form gives rise to μ -amino-peroxo-octammine, showing that both the μ -amino-peroxo-octammine, and the hexammine salts contain the same nucleus; whereas liquid ammonia with the asymmetrical salt yields μ -amino-peroxo-ol-octammine, showing that it differs from the symmetrical form in the position of NH_3 -groups.

The Ol-Salts.

J. G. Gentele,¹⁷ and S. M. Jörgensen prepared salts which A. Werner showed to be members of a series typified by **cobaltic diol-octamminochloride**:

which was prepared by treating the product obtained by dehydrating hydroxy-aquotetramminosulphate with ammonium chloride on a water-bath. The salt was also prepared by J. V. Dubsy, and H. Frank. It furnishes small, dark red crystals, which lose 4 mols. of water at 100° . Y. Shibata measured the absorption spectrum; H. R. Kruyt and P. C. van der Willigen, the streaming potential at a glass capillary; and E. Rosenbohm, and L. C. Jackson, the magnetic properties. According to A. Werner, the salt is readily dissolved by water, forming a neutral soln. H. Frank found that when the diol-octamminochloride is treated with acetic acid, it forms the anhydrous salt; and with conc. hydrochloric acid, the green dichlorotetrammine. A. Werner found that the treatment of the salt with fuming hydrochloric acid, saturated at -12° , yields the diaquotetrammine and dichlorotetrammine; J. V. Dubsy, that cold, conc. aq. ammonia, followed by the addition of alcohol, furnishes hydroxyaquotetramminochloride; and A. Werner, that ammonium oxalate, and potassium hydrophosphate give sparingly soluble, crystalline precipitates. K. Matsuno studied the flocculation of the hydrosol of arsenic sulphide by this salt.

A. Werner assumed that the two complex residues are combined together through the agency of the residual affinities of the oxygen atoms of the two OH-groups. The formula is in agreement with (i) the analyses; (ii) two mols.—*cis*-diaquotetrammine and *cis*-dichlorotetrammine—result from the decomposition of a mol. of the salt by hydrochloric acid; (iii) the acidic radicle is completely ionized in aq. soln. of the salt; and (iv) aq. soln. of the salt have a neutral reaction. The dihydrated cobaltic diol-octammine is a polymer of cobaltic hydroxyaquotetrammine. J. V. Dubsy regarded the salts formed by the loss of water from 2 mols. of hydroxyaquotetrammino-salts, say, $[\text{Co}(\text{NH}_3)_4(\text{OH})(\text{H}_2\text{O})]\text{Cl}_2$, to be the symmetrical diol-octammine; but the resolution of the diol-salts into *cis*-

diaquotetrammine and *cis*-dichlorotetrammine by mineral acids indicates an asymmetrical structure :

J. V. Dubsy, and H. Frank observed that when cobaltic hydroxyaquobisethylene-diaminedithionate is treated with acetic anhydride, and the product treated with ammonium chloride, **cobaltic diol-quaterethylenediaminechloride**, $[\text{en}_2\text{Co} \llcorner (\text{OH})_2 \gg \text{Co en}_2]$, is produced.

According to A. Werner, when cobaltic melanochloride is prepared at 5°, by exposing an ammoniacal soln. of cobaltous chloride to atmosphere air, there is formed, in addition to the products indicated above, cobaltic trichlorohydroxy-peroxo-hexamminochloride, $[(\text{NH}_3)_3\text{Cl}(\text{OH})\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_3\text{Cl}_2]\text{Cl}$; and when this product is treated with silver nitrate, it yields black nitrate in addition to the salts of μ -amino-peroxo-ol-hexammine. The nitrate is converted into sulphate, and when the sulphate is treated with an excess of ammonium chloride and dil. acetic acid, it finally yields brown, soluble, acicular crystals of **cobaltic hydroxyaquo-peroxo-ol-hexamminochloride** :

In favour of this formula, A. Werner showed (i) Conc. nitric acid splits the salt into trinitratotriammine; conc. hydrochloric acid converts it into dichloroaquo-triammine; and a soln. of sodium iodide in acetic acid forms diol- μ -acetato-hexammine, all in agreement with the assumption that the 6 NH_3 -groups are equally shared by the 2 cobalt atoms; (ii) Liquid ammonia forms hexammine- and pentammine salts, indicating that no NH_2 -bridge is present; (iii) Conc. sulphuric acid forms cobaltous sulphate, and a mixture of nitrogen and oxygen is evolved— $2\frac{1}{2}$ gram-atoms of oxygen for 2 gram-atoms of cobalt—and this agrees with the assumption that there is an O_2 -bridge between trivalent and quadrivalent cobalt atoms; and (iv) The aq. soln. of the salt has an alkaline reaction, indicating that an OH-group is present. The second OH-group is assumed to be bridged, because it is indifferent to dil. mineral acids, and with conc. hydrochloric acid, it is replaced by chlorine to form trichlorohydroxy-peroxo-hexammine.

A. Werner, and A. Werner and A. Baselli prepared **cobaltic μ -amino-ol-octamminochloride** :

by heating the chloride, obtained from Vortmann's fuscousulphate, with hydrochloric acid on a water-bath, and adding alcohol to precipitate the small, blood-red, lustrous prisms; and also by rubbing the fuscousulphate with fuming hydrochloric acid, and precipitating the clear liquid with alcohol. A. Werner and F. Beddow also obtained it as follows :

Green cobaltic μ -amino-peroxo-octammine nitrate, derived from the fuscousulphate, as indicated above, is warmed with a conc. aq. soln. of sulphurous acid until it becomes red, the cold mixture is treated with a few drops of nitric acid, and the violet precipitate which is obtained is triturated with conc. hydrochloric acid; the product is then dissolved in water, the hot, filtered soln. mixed with conc. hydrochloric acid, warmed on the water-bath for a short time, cooled, and mixed with an equal bulk of 90 per cent. alcohol. After being allowed to remain for 18 hrs., the μ -amino-ol-octamminochloride separates as a dark red precipitate.

This compound was at first regarded as an imido-salt, $[(\text{NH}_3)_4\text{Co}:\text{NH}.\text{Co}(\text{H}_2\text{O})(\text{NH}_3)_4]\text{Cl}_4$, but no imino-group could be detected; no salt formation took place either with acetic acid or dilute mineral acids; no acetylation took place by the action of acetic anhydride, and no nitroso-compound resulted from the action of nitrous acid. Further, the compounds in question were neutral in aq. soln. and not acid, as would be the case if the imino-formulation were correct. On the other hand, the amino-formulation accords well with the observed results. The cobalt atoms are all saturated with respect to co-ordination numbers. The complex radicle contains no water, and the salts do not, consequently, give an acid reaction when dissolved in water. The amino-group behaves like ammonia in metal ammonia compounds, being indifferent towards chemical reagents in the cold. The hydroxyl group, also, does not have the property of adding on hydrogen ions. The crystals of the salt were found by A. Werner to be slowly dissolved by cold water, to form a brownish-red soln.; warm water dissolves the salt more quickly. The aq. soln. decomposes with a protracted heating, but it is stable in soln. feebly acidified with acetic acid—36 parts of such a menstruum dissolves 1 part of salt at room temp. Hydrochloric acid converts it into chloropentamminochloride and dichlorotetramminochloride. The absorption spectrum was studied by Y. Shibata; and the flocculating action on the hydrosol of arsenic sulphide, by K. Matsuno.

According to A. Werner, and E. Birk, when cobaltic dichloroaquotriamminochloride is treated with a soln. of sodium hydroxide; or, according to A. Werner, when the cobaltic chlorodiaquotriamminosulphate is treated with soda-lye, and the product digested with barium chloride, there is formed **cobaltic triol-hexamminochloride** :

T. Das-Gupta and P. B. Sarkar obtained a better yield by using hexamethylenetetrammine instead of soda-lye. The pale red or brownish-red, acicular crystals suffer no loss at 80° , but are decomposed at 100° . When decomposed with halogen hydracids, the salts of this family group give quantitative yields of triamminecobalt salts, indicating that three ammonia residues are attached to each cobalt atom. The acid residues are readily ionized, as each salt can be transformed into the others by double decomposition. Their aq. soln. are quite neutral to litmus, and hence the salts cannot be aquo-salts. They are isomeric with the black, cobaltic hexol-dodecammines, say, $[\text{Co}(\text{OH})_6\{\text{Co}(\text{NH}_3)_4\}_3]\text{Cl}_6$. The constitution of these salts was discussed by T. M. Lowry. K. Matsuno studied the flocculating action on the hydrosol of arsenic sulphide.

In studying the oxidation of an alcoholic soln. of cobaltous chloride containing a little allylamine, A. Pieroni and A. Pinotti observed that red crystals of a compound which they first regarded as an octiesallyllamine, $\text{Co}(\text{C}_3\text{H}_5.\text{NH}_2)_8\text{Cl}_3$, are formed, but later A. Pieroni represented it by the formula : $[\text{Co}(\text{C}_3\text{H}_5.\text{NH}_2)_6(\text{O}_2)_2]\text{Cl}_3.\text{H}_2\text{O}_2$. W. R. Bucknall and W. Wardlaw showed that the analysis, mol. wt. determinations from f.p. and conductivity data, agree with the assumption that the compound is **cobaltic diol-peroxo-sexiesallyllaminechloride** :

The sexiesallyllamine-salt was obtained in purple-red, acicular crystals. Conc. hydrochloric acid yields a dark green, insoluble substance, which on warming dissolves to a bluish-green soln. of cobaltous chloride and allylamine hydrochloride. The addition of conc. hydrochloric acid to an aq. soln. of the complex chloride produces a green soln. which reverts to the blue colour of cobaltous chloride only on warming. Sulphuric acid decomposes the complex ion and forms cobaltous sulphate. With silver nitrate soln. the complex chloride gives an immediate precipitate of silver chloride; together with a red precipitate, in conc. soln. of the complex nitrate. Ammonium sulphide immediately precipitates the

cobalt as sulphide. The complex salt reacts, on warming, with potassium iodide soln., with the liberation of iodine; with potassium bromide, however, no oxidation could be detected.

Analogous products were obtained by E. G. V. Percival and W. Wardlaw with propylamine, and benzylamine in place of allylamine. Red crystals of **cobaltic diol-peroxo-sexiespropylaminechloride**, $[(C_3H_7.NH_2)_3Co \equiv (OH)_2O_2 \equiv Co(C_3H_7.NH_2)_3]Cl_3$, were prepared by oxidizing dry cobaltous chloride in the presence of dry alcohol and dry *n*-propylamine. The cryoscopic and conductivity determinations of the aq. soln. indicate that four ions are formed. The complex chloride is very soluble in water, giving a neutral soln., and the addition of nitric acid produces, as in the case of the allylamine complex, an insoluble nitrate, all the chlorine having been displaced. Heated to 70°, an aq. soln. of the salt yields brown cobalt hydroxide, and propylamine is liberated. Ammonium sulphide immediately precipitates cobalt as sulphide. Conc. hydrochloric acid gives a green soln. The complex salt liberates iodine from potassium iodide soln. on warming. When cobaltous chloride is similarly treated in the presence of dry alcohol in dry benzylamine, **cobaltic triol-sexiesbenzylaminechloride**, $[(C_6H_5.CH_2.NH_2)_3Co \equiv (OH)_3 \equiv Co(C_6H_5.CH_2.NH_2)_3]Cl_3$, is formed. The colour of the salt is purple-red, and it is insoluble in water and alcohol. A suspension in water decomposed on being heated to 70°, with formation of cobalt hydroxide and the liberation of benzylamine and benzaldehyde. Cold, conc. nitric acid did not form a nitrate. Iodine was not liberated from potassium iodide soln. by this salt (unlike the peroxo-compounds) on warming in the presence of acetic acid. There is evidence of the formation of an analogous product with ethylamine, but not with methylamine, diethylamine, and piperidine. Thus, E. G. V. Percival and W. Wardlaw concluded that the oxidation of cobaltous chloride in alcohol in the presence of amines does not always produce polynuclear complexes. Only the primary amines, containing the $CH_2.NH_2$ -group, have given successful results. Aniline, pyridine, and quinoline formed products which were not amenable to further oxidation by the method outlined above. Aniline, for example, gave an insoluble, blue compound of the composition $CoCl_2.3C_6H_5NH_2$, which on re-crystallization from alcohol yielded E. Lippmann and G. Vortmann's $CoCl_2(C_6H_5.NH_2)_2(C_2H_5.OH)_2$. This is taken to mean that there is probably formed a stable co-ordination compound, $[CoCl_2(C_6H_5.NH_2)_2(C_2H_5.OH)_2]$, which is not susceptible to atmospheric oxidation.

A. Werner prepared cobaltic diaquo- μ -amino-ol-hexamminonitrate, $[(NH_3)_3(H_2O)Co \equiv (NH_2)(OH) \equiv Co(H_2O)(NH_3)_3](NO_3)_4.4H_2O$, as follows:

Twenty grams of melanochloride are triturated with a slightly acidic soln. of 36 grams of silver nitrate in 60 c.c. of water, and the mixture heated to 50° for some time. The silver chloride is collected and heated, at 80°, with separate quantities of 60 c.c. of very weak nitric acid, until it is colourless. To the united red extracts is added alcohol until incipient crystallization; on cooling in a freezing mixture, red crystals of the nitrate separate. After solution in water and re-precipitation with conc. nitric acid, garnet-red, flat, quadratic prisms are obtained.

When a warm soln. of this salt is saturated with ammonium bromide, the product triturated with moist silver chloride, and the aq. soln. treated with absolute alcohol, bright red, acicular crystals of **cobaltic μ -amino-di-ol-hexamminochloride**:

are formed. The salt is freely soluble in water, and the soln. has a neutral reaction. When warmed with nitric acid, this salt forms the nitratoquo- μ -amino-ol-hexamminonitrate; which, with liquid ammonia, passes into μ -amino-ol-octamminonitrate, and then into μ -amino-decamminonitrate. All this is taken to establish the hypothesis that the amine-group in the compound is bridged between the two cobalt atoms.

A. Werner and co-workers treated the black chloride, obtained by the action of silver nitrate on melanochloride, with silver nitrate, and saturated the filtrate with ammonium bromide. The resulting bromide was treated with silver chloride, and ammonium chloride, or alcohol, was added to the filtrate to precipitate **cobaltic μ -amino-peroxo-ol-hexamminochloride** :

The salt can be re-crystallized from a conc. aq. soln. The water can be driven off by heat. The aq. soln. has a neutral reaction, and therefore it is not an aquo-salt, nor a hydroxy-salt. Fuming nitric acid furnishes trinitratotriamine, meaning that the six NH_3 -groups are shared equally between the two cobalt atoms. Hydrochloric acid added to the conc. aq. soln. yields the dichloro- μ -amino-peroxo-hexamminochloride. The μ -amino-peroxo-ol-hexammines are produced by the degradation of the μ -amino-peroxo-octammines, and when an aq. soln. of this product is heated with ammonium chloride, and the liquid saturated with hydrogen chloride, cobaltic hexamminochloride separates out; and when reduced with potassium iodide and acetic acid, the μ -amino-diol-hexammino-salt is formed, showing that the cobalt atoms are joined by an amine-group.

A. Werner and G. Jantsch found that the oxidation of aq. soln. of cobaltous salts containing some ethylenediamine, furnishes a series of quaterethylenediamine-salts. If cobaltous chloride is employed, and the oxidized liquor is treated with sodium chloride, **cobaltic-tetrol-quaterethylenediaminochloride** :

is formed along with cobaltic trisethylenediaminechloride. The latter is removed by washing the precipitate with water, and the tetrol-salt remains as a bright red powder with a faint blue tinge. When the tetrol-salt is treated with cold hydrochloric acid, no halogen is evolved, but a mol. of the salt yields a mol. of cobaltous chloride, and 2 mols. of *cis*-diaquobisethylenediaminechloride. The aquo-mols. in the 2 mols. of the diaquo-salt are not present in the parent salts, since these compounds do not react like diaquo-salts, but the complex of the parent salt contains 4 atoms of oxygen which must be employed in building up the molecule. The effect of hydrochloric acid shows that these compounds are formed by the union of a mol. of a cobaltous salt, with 2 mols. of a cobaltic dihydroxybisethylenediamine-salt. The aq. soln. has a neutral reaction, so that the OH-groups are bridged. They also contain 2 mols. of water retained by them in the dried state. The whole of the acid radicle is ionized in aq. soln. All this is in agreement with the formula assigned to the salt.

According to A. Werner, in preparing cobaltic triol-hexammino-sulphate by leaving cobaltic chlorodiaquotriamminosulphate in a soln. of ammonium bromide for several days, the reddish-brown mother-liquor, when strongly cooled, and mixed with conc. hydrochloric acid, gives a green precipitate. A soln. of this precipitate in water, acidulated with acetic acid, deposits an impure sulphate when treated with sulphuric acid. When this sulphate is treated with ammonium chloride, it furnishes dark green crystals of **cobaltic hexol-hexamminochloride** :

When this salt is decomposed by hydrochloric acid, dichloro-aquotriamminochloride, cobaltous chloride, and chlorine are formed, indicating that the six NH_3 -groups

are shared equally by 2 cobalt atoms, and chlorine is liberated as the third cobalt atom passes from the tervalent to the bivalent form. There is no evidence of any amino-linkages. All three acid-radicles are ionogenic. The salt forms with water a yellowish-brown soln. When soln. of this salt are treated with hydrochloric acid, in the cold, one of the ol-linkages is destroyed, and there are formed green crystals of **cobaltic diaquo-pentol-hexamminochloride**,

S. M. Jörgensen prepared a series of salts which he called *anhydrobasische Tetrammin-Diaquodiamminkobaltsalze*; and A. Werner, *Dodekammine-hexol-tetrakobalt (111)-salze*. S. M. Jörgensen prepared the chloride—**cobaltic hexol-dodecamminochloride** :

by dissolving chloroaquotetramminochloride in dil. aq. ammonia, and after allowing the mixture to stand in a closed flask for 24 hrs., adding 90 per cent. alcohol. The salt is precipitated in small, hexagonal tablets, which are dark violet, almost black in colour. A. Werner obtained the salt in this way, and also by warming the sulphate of the series with a soln. of barium chloride, and treating the filtered, dark brown liquid with alcohol. E. Birk prepared the salt by dissolving 10 grms. of cobaltic triaquotriamminochloride in 10 c.c. of water, adding slowly 3.1 c.c. of a 10 per cent. aq. soln. of potassium hydroxide, and then 30 to 50 c.c. of alcohol. Y. Shibata measured the absorption spectrum. S. Berkman and H. Zocher found the magnetic susceptibility to be -0.22×10^{-6} mass unit. According to S. M. Jörgensen, the salt is freely soluble in water, but after a time the aq. soln. decomposes, and deposits a dark grey, amorphous mass. Y. Shibata also noted the hydrolysis of the salt in aq. soln. S. M. Jörgensen observed that the salt is decomposed when gently warmed with 1 : 1-hydrochloric acid, to furnish cobaltic chloroaquotetramminochloride, cobaltous chloride, chlorine, ammonium chloride, and water; and when heated with the 1 : 2-acid, it is almost completely converted into dichlorotetramminochloride. A freshly-prepared, 1 per cent. aq. soln. gives characteristic precipitates with many metal salts, and acids—e.g., brown crystalline precipitates with dil. nitric acid, hydrofluosilicic acid, ammonium sulphate, and sodium dithionate; grey or yellow precipitates with mercuric chloride, with potassium chromate or chloroplatinite, and with sodium chloroaurate, or chloroplatinate; sodium pyrophosphate gives a brown turbidity; and sodium hydrophosphate gives no precipitate. K. Matsuno studied the flocculating action on the hydrosol of arsenic sulphide.

In addition to the ammonia-series of hexol-dodecammines, prepared by S. M. Jörgensen, there is a similar ethylenediamine-series, prepared by A. Werner. Brown, soluble, acicular crystals of **cobaltic hexol-sexiesethylenediaminechloride** :

were obtained by exposing a soln. of cobalt chloride and ethylenediamine to atmospheric oxidation. When dissolved in conc. hydrochloric acid, *cis*-diaquobis-ethylenediaminechloride is formed, and similarly with hydrobromic acid; when evaporated with dil. hydrochloric acid, *trans*-dichlorobisethylenediaminechloride is produced; and when treated with a soln. of potassium hydroxide, *cis*-hydroxy-aquobisethylenediaminechloride.

S. M. Jörgensen represented the ammonia-series of these salts by formulæ of

the type: $(\text{HO})(\text{H}_2\text{O})_2(\text{NH}_3)_2\text{Co.O.Co}(\text{NH}_3)_4\text{Cl}_2$, but A. Werner's objections were as follow:

(i) The salts cannot contain HO directly attached to cobalt, since they do not yield aquo-salts by treatment with mineral acid; (ii) in the chloride, the presence of chlorine directly attached to cobalt is contrary to the fact that this salt is converted into a halogen-free sulphate by the action of soluble sulphates; (iii) the estimation of the products of decomposition of these salts by hydrochloric or hydrobromic acid leads to results contrary to those anticipated by S. M. Jörgensen's formula. Thus, the sulphate of the ammonia series yields 81.1 per cent. of diaquotetramminecobalt chloride, and the nitrate of the ethylenediamine series, 80.71 per cent. of 1:6-dichlorodiethylenediaminecobalt nitrate, whereas the amounts calculated from S. M. Jörgensen's formula are 68.1 per cent. and 54.6 per cent. respectively. If the mol. formulæ of these complex salts are doubled and A. Werner's constitutional formula is adopted, the observed percentages in the preceding decompositions agree well with the calculated values; (iv) the estimation of the chlorine evolved by the action of cold conc. hydrochloric acid on salts of either series agrees well with the theory that in the molecule of these salts, 4 cobalt atoms are present, one of which passes from the trivalent to the bivalent state during the decomposition. According to S. M. Jörgensen's formula, the products of decomposition must contain one cobalt atom in the form of a tetrammine salt, and one cobalt atom as a diammine salt; the latter, in spite of numerous attempts, cannot be detected; (v) the sulphate of the ammonia series is decomposed by dil. sulphuric acid, yielding oxygen, and by conc. sulphuric acid, evolving oxygen and nitrogen in quantities which agree with those calculated from A. Werner's formula.

A. Classen and B. Zahorsky¹⁸ described a **cobaltosic pyridine**, $\text{CoCl}_2 \cdot \text{CoCl}_3 \cdot 5\text{C}_5\text{H}_5\text{N}$.

§ 17. The Cobaltic Ammines

Es giebt wohl kaum eine andere Körperklasse, über die es viel geschrieben worden ist, wie über diese metallhaltigen Ammoniake.—C. W. BLOMSTRAND (1869).

In 1798, B. M. Tassaert,¹ in his paper, *Analyse du cobalt de Tunaberg*, mentioned the formation of compounds of ammonia with the salts of cobalt, and some isolated observations on the subject were made during the first half of the nineteenth century by W. Beetz, E. H. Dingler, L. Gmelin, H. Hess, C. H. Pfaff, J. L. Proust, C. F. Rammelsberg, and G. C. Winkelblech. The subject began to attract attention about the middle of the nineteenth century, and memoirs on the cobalt-ammonia compounds were subsequently published by C. H. D. Bödeker, C. D. Braun, E. Carstanjen, F. Claudet, C. E. Claus, E. Frémy, J. G. Gentile, F. A. Genth, O. W. Gibbs and F. A. Genth, W. Gregory, J. M. Krok, C. Künzel, E. J. Mills, J. B. Rogojsky, F. Rose, H. Schiff, A. Terreil, and C. Weltzien.

Meanwhile, analogous compounds of chromium, and some of the platinum metals had been investigated, and it was recognized that the **metal-ammonia bases**, as they were called, formed a special department in chemistry. Attempts were made by C. H. D. Bödeker, O. W. Gibbs and F. A. Genth, H. Schiff, C. Weltzien, etc., to bring order into the chaotic accumulation of facts. It was recognized that certain groups of atoms acted as bases, and each of these bases in turn formed, with various acidic radicles, a series of salts. E. Frémy named the different bases he had studied after the dominant colour of some of the leading members of the series. Although this method of naming the compounds had ultimately to give way to a more systematic nomenclature, yet it is often employed in order to evade using the more ponderous systematic names. Thus, the members of a family of salts with six NH_3 -groups per atom of cobalt were called *luteo-salts*—from *luteus*, yellow—in allusion to the yellow colour of the chloride, sulphate, and nitrate; the members of one of the families with five NH_3 -groups per atom of cobalt were called *purpureo-salts*—from *purpura*, purple—in allusion to the purple tint of the chloride, sulphate, and nitrate; and the members of one of the families, with four NH_3 -groups per atom of cobalt were called *praseo-salts*—from *πρασῖος*, leek-green—in allusion to the dominant colour of the salts.

In 1869, C. W. Blomstrand² suggested a system of chain formulæ to represent the structure of these compounds; it was based on the electrochemical or dualistic theory of J. J. Berzelius—1. 8, 16—and on the recognized valencies of the contained elements. At that time, cobaltic chloride was represented by the formula Co_2Cl_3 ,

and, accordingly, a pair of cobalt atoms was considered to be a kind of sexivalent radicle. Instead of using the symmetrical formula $(\text{Cl}-\text{NH}_3-\text{NH}_3)_3 \equiv \text{Co}_2 \equiv (\text{NH}_3-\text{NH}_3-\text{Cl})_3$, where Cl is employed to represent the univalent radicle as well as an atom of chlorine, he suggested for the dodeca-ammonia and deca-ammonia bases, respectively :

Luteo-salt

Purpureo-salt

in order to explain why, in passing from the luteo-salt to the purpureo-salt, two of the six acidic Cl-radicles of the purpureo-salts are no longer susceptible to, say, silver nitrate, which immediately attacks all the six acidic radicles of the luteo-salts. It was assumed that two of the Cl-radicles in close contact with the cobalt atoms were not so susceptible to attack as were those with intervening NH_3 -groups. The removal of two more NH_3 -groups to furnish the praseo-salts resulted in the removal of two more acidic radicles from the zone of attack. S. M. Jörgensen therefore modified C. W. Blomstrand's formulæ to :

Luteo-salt

Purpureo-salt

Praseo-salt

Molecular weight determinations by L. F. Nilson and O. Pettersson, and J. Petersen on the analogous chromic-ammonia salts, and of A. Werner and C. Herty, and A. Werner and A. Miolati on the cobaltic-ammonia salts, showed that the doubled formulæ must give way to the simpler chain formulæ :

Luteo-salt— $\text{Co}(\text{NH}_3)_5\text{Cl}_2$ Purpureo-salt— $\text{ClCo}(\text{NH}_3)_5\text{Cl}_2$ Praseo-salt— $\text{Cl}_2\text{Co}(\text{NH}_3)_4\text{Cl}$

These formulæ explain how it is that in metathetical reactions, one chlorine atom remains associated with the cobalt and NH_3 -groups in the penta-ammonia compounds, and two chlorine atoms, in its tetra-ammonia compounds ; how conc. sulphuric acid will remove only two of the three Cl-atoms in the penta-ammonia salts, and only one of the three Cl-atoms in the tetra-ammonia salts ; and why, if a bromine be substituted for chlorine in different ways, say, in the penta-ammonia salts, the mol. vol. of the compounds are different. Thus :

277.7

281.6

319.9

S. M. Jörgensen also found that the NH_3 -groups may be replaced by aqua- or H_2O -groups, as well as by pyridine, and other groups. He then inquired if the chains of ammonia radicles are straight or branched. If there are two branches, the one labile hydrogen must behave differently, since the chain in the one case is, say, $\text{Co}-\text{NH}_3-\text{NH}_3-\text{NH}_3-\text{Cl}$, and in the other case, say,

He found that since with pyridine no labile hydrogen atoms and no forked chains are possible when pyridine groups are substituted for NH_3 -groups in the compounds, the resulting metal-pyridine salts behave just like the metal-ammonia salts, and this makes it highly probable that the metal ammonias do not contain the NH_4 -group, and that the NH_3 -chains are not branched.

The conductivity determinations showed that these different families of salts contain cobalt as part of a series of complex cations which are respectively ter-, bi-, and uni-valent, according as the complex cation has none, one, or two NH_3 -groups replaced by acidic radicles, which then become part of the complex cation. If another substitution of the NH_3 -groups be made, as in the trinitrite, $(\text{NH}_3)_3\text{Co}(\text{NO}_2)_3$, the complex is null-valent. If still another NH_3 -group be displaced by the acidic radicle, the complex is no longer cationic, or basic, but rather is anionic or acidic, since it is univalent and forms salts with the bases. The replacement of four NH_3 -groups thus furnishes a univalent anion; and in an analogous manner, the replacement of a fifth NH_3 -group, yields a bivalent anion.

The term **metal-ammines**, or simply **ammines**, came to be employed for the metal-ammonias. Ammine is the name applied specifically to an NH_3 -group; and generally to NH_3 - or equivalent groups. Then followed A. Werner's co-ordination theory—8, 49, 19—in which no very definite hypothesis was made respecting the grouping of the complex anions or cations within the complex. This hypothesis enabled nearly all the known complex metal-ammonia compounds to be classified in a consistent manner. In A. Werner's classification, the cobalt ammines are arranged in two groups, according as the nucleus has one or more cobalt atoms. If A be employed to represent an NH_3 - or an equivalent group, and X a univalent acidic radicle, and M a univalent base, there are five families in the group with one cobalt atom in the nucleus to be considered:

In contrast with the **Blomstrand and Jörgensen's chain theory**, A. Werner's system of classification has been called **Werner's nucleus theory**, or, for reasons indicated 8, 49, 19, **Werner's co-ordination theory**. Speculations as to (i) the disposition of the groups of radicles about the central cobalt atom, and (ii) the nature of the different kinds of valency bonds, came later—*vide* the platinum ammines. The constitution was discussed in a number of books:

O. Angern, *Die Ammine des Kobalts*, in *Gmelin's Handbuch der anorganischen Chemie*, Berlin, 58, 1930; A. E. van Arkel and J. H. de Boer, *Chemische Bindung als elektrostatische Erscheinung*, Leipzig, 1931; W. A. Noyes, *Journ. Amer. Chem. Soc.* 55, 4889, 1933; P. Sénéchal, *Introduction à la chimie des complexes*, Paris, 1913; R. Weinland, *Einführung in die Chemie der Komplex-Verbindungen*, Stuttgart, 1919; A. Werner, *Neuere Anschauungen auf dem Gebiete der anorganischen Chemie*, Braunschweig, 1923; G. Wittig, *Stereochemie*, Leipzig, 1930.

The following is an outline sketch of the cobaltic ammines in accord with the plan adopted with the chromic ammines—11, 60, 24.

A.—Compounds with one Cobalt atom in the nucleus.

I.—**The hexammine family**, or compounds of the tervalent basic group: $[\text{CoA}_6]^{+++}$.

(i) **Hexammines**, $[\text{Co}(\text{NH}_3)_6]\text{X}_3$. These salts are the so-called **cobaltic luteo-salts**—*leuteus*, yellow. They include (1) Hydroxide; (2)

Fluoride, and its double salts with boron, titanium, and vanadium fluorides; (3) Hydrofluoride; (4) Chloride and its ammonia addition compounds, and double salts with the copper, zinc, cadmium, mercuric, tin, lead, antimony, bismuth, gold, platinum, iridium, ruthenium, and rhodium chlorides; (5) Chlorofluoride; (6) Chlorite; (7) Chlorate; (8) Perchlorate; (9) Chloroperchlorate; (10) Bromide and its ammonia addition compounds, and double salts with cadmium, mercury, lead, bismuth, gold, and iridium bromides; (11) Hydrobromate; (12) Iodide and its ammonia addition compounds, and double salts with mercury and bismuth iodides; (13) Polyiodides; (14) Chlorohydroiodate; (15) Sulphite; (16) Chlorosulphite; (17) Sulphate, and double salts with ammonium thallium, cerium, and lanthanum sulphates; (18) Hydrosulphates; (19) Chlorosulphate, and double salts with ammonium, and mercury sulphates; (20) Chloratosulphate; (21) Perchloratosulphate; (22) Bromosulphate, the double salt with gold; (23) Iodosulphate; (24) Sulphatopersulphate; (25) Chlorothiosulphate; (26) Selenate, and the double salt with ammonium; (27) Hydroselenate; (28) Chloroselenate; (29) Bromoselenate; (30) Iodoselenate; (31) Selenatopersulphate; (32) Nitrite; (33) Nitrate; (34) Hydronitrate; (35) Fluonitrate; (36) Iodonitrate; (37) Sulphatonitrate; (38) Amidosulphonate; (39) Imidosulphate; (40) Nitrilosulphonate; (41) Hydroxylaminosulphate; (42) Carbonate; (43) Hydrocarbonate; (44) Chlorocarbonate; (45) Fluosilicate; (46) Hypophosphate; (47) Orthophosphate; (48) Hydrophosphate; (49) Pyrophosphate, and double salts with sodium pyrophosphate; (50) Hypopyrophosphate; (51) Chlorometaphosphate; (52) Chromate; (53) Dichromate; (54) Chlorochromate; (55) Bromochromate; (56) Iodochromate; (57) Molybdates; (58) Iodomolybdate; (59) Tungstates; (60) Permanganate; (61) Chloropermanganate; (62) Bromopermanganate; (63) Acetate; (64) Oxalate, and double salt with cadmium and cobalt oxalates; (65) Hydroxalate; (66) Chloroxalate; (67) Oxalatochromate; (68) Picrate; (69) Dipicrylamine; (70) Nitroso- β -naphtholoxide; (71) 2:4-Dinitro- α -naphtholsulphonate; (72) *m*-Nitrobenzeneazosalicylate; (73) 2:4-Dinitro- α -naphtholsulphonates; (74) Naphthalene- β -sulphonate; (75) Hexacyanoferrite; (76) Hexacyanoferrate; (77) Thiocyanate, and double salts with silver, mercury, and platinum thiocyanates; (78) Trisulphitocobaltate; (79) Hexanitrocobaltate; (80) Tetranitrodiamminocobaltate; (81) Trioxalatocobaltate; (82) Dinitro-oxalatodiamminocobaltate; and (83) Potassium and ammonium octoborates.

- (ii) *Hexahydroxylamines*, $[\text{Co}(\text{NH}_2\text{OH})_6]\text{X}_3$, include (1) Chloride; (2) Bromide; (3) Sulphate; (4) Nitrate; and (5) Oxalate.
- (iii) *Hydroxylaminebisethylenediamineammines*, $[\text{Co}(\text{NH}_3)(\text{NH}_2\text{OH})\text{en}_2]\text{X}_3$, represented by the dextro- and laevo-forms of (1) Hydroxide; (2) Chloride; (3) Perchlorate; (4) Bromide; (5) Iodide; (6) Dithionate; and (7) Nitrate.
- (iv) *Trisethylenediamines*, $[\text{Co en}_3]\text{X}_3$, include (1) Hydroxide; (2) Fluoride; (3) Chloride, and double salts with sodium, copper, mercury, cobalt, bismuth, nickel, iridium, and platinum chlorides; (4) Perchlorate; (5) Bromide, and a double salt with mercury bromide; (6) Iodide, and a double salt with silver iodide; (7) Polyiodide; (8) Sulphate; (9) Hydrosulphate; (10) Chlorosulphate; (11) Thiosulphate; (12) Selenate; (13) Hydroselenate; (14) Nitrite; (15) Nitrate; (16) Tartrate; (17) Chlorotartrate; (18) Bromotartrate; (19) Trioxalatochromate; (20) Trioxalatocobaltate; (21) Bromodimethyl-

- succinate; (22) Thiocyanate; (23) Trithiocyanatomercurate (24) Hexacyanochromate.
- (v) *Trispropylenediamines*, or *triscyclopentanediamines*, $[\text{Co pn}_3]\text{X}_3$, include (1) Hydroxide; (2) Chloride; (3) Chlorate; (4) Perchlorate; (5) Bromide; (6) Iodide; (7) Nitrate; (8) Thiocyanate; (9) Hexacyanochromate; (10) Hexacyanoferrate; (11) Hexacyanocobaltate; (12) Trioxalatochromate; and (13) Chlorotartrate.
- (vi) *Trisbutylenediamines*, $[\text{Co bn}_3]\text{X}_3$, represented by (1) Bromide; (2) Iodide; and (3) Thiocyanate.
- (vii) *Trisphenylenediamines*, $[\text{Co(o-C}_6\text{H}_8\text{N}_2)_3]\text{X}_3$, are represented by the chloride.
- (viii) *Bistriaminopropanes*, $[\text{Co}(\alpha\beta\gamma\text{-C}_3\text{H}_{11}\text{N}_3)_2]\text{X}_3$, include (1) Chloride, and the double salt with platinum chloride; (2) Iodide; (3) Thiocyanate; and (4) Camphorate.
- (ix) *Bisethylenediaminediammines*, $[\text{Co}(\text{NH}_3)_2\text{en}_2]\text{X}_3$, include (1) Chloride, and double salts with mercury, cobaltous, gold, and platinum chlorides; (2) Bromide; (3) Iodide; (4) Polyiodide; (5) Dithionate; (6) Nitrate; (7) Chloroxalate; (8) Iodoxalate; and (9) Bromocamphorsulphonate.
- (x) *Bispropylenediaminediammines*, $[\text{Co}(\text{NH}_3)_2\text{pn}_2]\text{X}_3$, include (1) Chloride, and double salts with gold, mercury, tin and cobaltous chlorides; (2) Bromide; (3) Iodide; (4) Dithionate; (5) Nitrate; and (6) Dichromate.
- (xi) *Ethylenediaminedicyclopentanediamines*, $[\text{Co en}(\text{C}_5\text{H}_{12}\text{N}_2)_2]\text{X}_3$, represented by the (1) Chloride; (2) Bromide; and (3) Iodide.
- (xii) *Bisethylenediaminepropylenediamine*, $[\text{Co en}_2\text{pn}]\text{X}_3$, include (1) Hydroxide; (2) Bromide; (3) Iodide; (4) Thiocyanate; (5) Hexacyanochromate; (6) Hexacyanocobaltate; (7) Trioxalatochromate; and (8) Trioxalatocobaltate.
- (xiii) *Bisethylenediaminecyclopentaminediamines*, $[\text{Co en}_2(\text{C}_5\text{H}_{12}\text{N}_2)]\text{X}_3$, include (1) Chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Nitrate; and (6) Bromotartrate.
- (xiv) *Bisethylenediaminepyridinediammines*, $[\text{Co}(\text{NH}_3)\text{en}_2\text{py}]\text{X}_3$, represented by the bromide.
- (xv) *Bisethylenediamine- α -phenanthrolines*, $[\text{Co en}_2(\text{C}_{12}\text{H}_8\text{N}_2)]\text{X}_3$, include (1) Chlorate; (2) Bromide; (3) Iodide; (4) Sulphate; (5) Chlorosulphate; (6) Nitrate; (7) Tartrate; and (8) Bromocamphorsulphonate.
- (xvi) *Bistriaminotriethylaminesesexiesethylenediamines*, $[\text{Co en}_6(\text{C}_6\text{H}_{18}\text{N}_4)_2]\text{X}_3$, include (1) Chloride; (2) Chlorate; (3) Perchlorate; (4) Iodide; (5) Iodate; (6) Sulphate; (7) Chlorosulphate; (8) Dithionate; (9) Nitrate; and (10) Iodotartrate.
- (xvii) *Trisdiaminopentanes*, $[\text{Co ptn}_3]\text{X}_3$, represented by the $\alpha\beta\delta$ - and the $\beta\beta\delta$ -salts, (1) Chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Dithionate; (6) Nitrate; and (7) Bromo- α -tartrate.
- (xviii) *Bisethylenediaminodiaminopentane*, $[\text{Co en}_2\text{ptn}]\text{X}_3$, represented by the bromide.
- (xix) *Aquopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{X}_3$, are the **cobaltic roseo-salts**—from *rosa*, a rose—of E. Frémy, and were so called in allusion to the red colour of the chloride, sulphate, and nitrate. They include (1) Hydroxide; (2) Fluoride; (3) Hydrofluoride; (4) Chloride, and its ammonia addition compounds, and double salts with the chlorides of zinc, cadmium, mercury, gold, iridium, and platinum; (5) Chlorite; (6) Chlorate; (7) Perchlorate; (8) Bromide and ammonia addition compounds, as well as double salts with the chlorides of cadmium, mercury, gold, iridium, and platinum; (9) Iodide, and ammonia addi-

tion compounds, as well as a double salt with the iodide of mercury ; (10) Sulphite, and a double salt with sodium sulphite ; (11) Trisulphitocobaltate ; (12) Sulphate, and a double salt with sodium phosphate ; (13) Hydrosulphate ; (14) Chlorosulphate ; (15) Chloratosulphate ; (16) Perchloratosulphate ; (17) Bromosulphate ; (18) Iodosulphate ; (19) Selenate ; (20) Nitrate ; (21) Hydronitrate ; (22) Iodonitrate ; (23) Sulphatonitrate ; (24) Amidosulphonate ; (25) Imidosulphonate ; (26) Nitrilosulphonate ; (27) Hydroxylaminetrisulphonate ; (28) Carbonate ; (29) Orthophosphate ; (30) Hydrophosphate ; (31) Pyrophosphate ; (32) Hypopyrophosphate ; (33) Vanadate ; (34) Dichromate ; (35) Molybdates ; (36) Tungstates ; (37) Oxalate ; (38) Hydroxalate ; (39) Trioxalatocobaltate ; (40) 2 : 4 and 2 : 6-Dinitrophenol ; (41) Picrate ; (42) Dipicrylamine ; (43) 2 : 4-Dinitro- α -naphtholsulphonate ; (44) Naphthalene- β -sulphonate ; (45) Nitrato-tartrate ; (46) Nitratosuccinate ; (47) Nitroadipate ; (48) Nitrato-fumarate ; (49) Nitratomethionate ; (50) Hexacyanochromate ; (51) Tetra isothiocyanatodiamminochromate ; (52) Hexacyanoferrate ; (53) Hexacyanocobaltate ; (54) Potassium and ammonium octoborates ; (55) Ammonium cobaltic aquopentammineoctoborate.

- (xx) *Aquobisethylenediamineammines*, $[\text{Co}(\text{NH}_3)_n(\text{H}_2\text{O})]\text{X}_3$, include (1) Chloride as double salts with platinum ; (2) Bromide ; (3) Iodide ; and (4) Nitrate.
- (xxi) *Aquopyridinetetrammines*, $[\text{Co}(\text{NH}_3)_4\text{py}(\text{H}_2\text{O})]\text{X}_3$, represented by the nitrate.
- (xxii) *Aquodipyridinetriammines*, $[\text{Co}(\text{NH}_3)_3\text{py}_2(\text{H}_2\text{O})]\text{X}_3$, represented by the (1) Chloride ; and (2) Bromide.
- (xxiii) *Diaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})]\text{X}_3$. These salts have been called the **cobaltic roseotetrammine-salts**, in allusion to the colour of the chloride, etc. The cobaltic roseo-salts are the aquopentammines. They include (1) Hydroxide ; (2) Chloride ; (3) Bromide ; (4) Iodide ; (5) Sulphate, and a basic sulphate ; (6) Hydrosulphate ; (7) Perchloratosulphate ; (8) Chlorosulphate, represented by a double salt with platinum ; (9) Bromosulphate, and double salts with gold and iridium ; (10) Selenate ; (11) Nitrate ; (12) Amidosulphonate ; (13) Orthophosphate ; (14) Pyrophosphate ; (15) Molybdate ; (16) Acetate ; (17) Oxalate ; (18) Trioxalatocobaltate ; (19) Picrate ; (20) Naphthalene- β -sulphonate ; and (21) Hexacyanocobaltate.
- (xxiv) *Diaquobisethylenediamines*, $[\text{Co en}_2(\text{H}_2\text{O})_2]\text{X}_3$, include (1) Hydroxide ; (2) Chloride ; (3) Bromide ; (4) Iodide ; (5) Sulphate ; (6) Dithionate ; (7) Nitrate ; and (8) Thiocyanate.
- (xxv) *Diaquobis trimethylenediamines*, $[\text{Co tr}_2(\text{H}_2\text{O})_2]\text{X}$, represented by the Nitrate.
- (xxvi) *Diaquobispyridinediammines*, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{H}_2\text{O})_2]\text{X}_3$, include (1) Chloride ; (2) Bromide ; (3) Hydrosulphate ; (4) Dithionate ; () Hydroselenate ; and (6) Nitrate.
- (xxvii) *Triaquotriammines*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_3]\text{X}_3$, include (1) Chloride, and the double salt with platinum ; (2) Perchloratosulphate ; and (3) Nitrate.
- (xxviii) *Tetraquodiammines*, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_4]\text{X}_3$, include (1) Chloride ; and (2) Nitrate.

II.—The Pentammine family, or compounds of the bivalent basic group : $[\text{CoA}_2\text{X}]^+$.

(a) *Pentammines with Univalent Radicle in the Complex.*

- (i) *Hydroxypentammines*, $[\text{Co}(\text{NH}_3)_5(\text{OH})]\text{X}_2$, or the **cobaltic roseo-salts**, include (1) Hydroxide ; (2) Chloride ; (3) Bromide ; (4) Iodide ; (5) Sulphate ; (6) Persulphate ; (7) Dithionate ; (8) Nitrate ; and (9) Trioxalatocobaltate.

- (ii) *Hydroxybispyridinetriammines*, $[\text{Co}(\text{NH}_3)_3\text{py}_2(\text{HO})]\text{X}_2$, represented by (1) Chloride; (2) Bromide; (3) Iodide; (4) Dithionate; (5) Nitrate; and (6) Thiocyanate.
- (iii) *Hydroxypyridinetetrammines*, $[\text{Co}(\text{NH}_3)_4\text{py}(\text{HO})]\text{X}_2$, represented by the Nitrate.
- (iv) *Hydroxyaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{OH})]\text{X}_2$, include (1) Chloride; (2) Bromide, and the double salt with iridium bromide; (3) Sulphate; (4) Bromosulphate, represented by a double salt with iridium; (5) Dithionate; (6) Selenate; (7) Nitrate; (8) 2 : 4 Dinitro- α -naphthyl-7-sulphonate; (9) Picrate; and (10) Dipicrylamide.
- (v) *Hydroxyaquobisethylenediamines*, $[\text{Co en}_2(\text{H}_2\text{O})(\text{OH})]\text{X}_2$, include cis- and trans-salts: (1) Chloride, and the double salt with iridium chloride; (2) Bromide; (3) Iodide; (4) Dithionate; (5) Nitrate; (6) Hydrophosphate; and (7) Thiocyanate.
- (vi) *Hydroxyaquobispyridinediammines*, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{H}_2\text{O})(\text{OH})]\text{X}_2$, include (1) Chloride; (2) Bromide; (3) Dithionate; (4) Nitrate; and (5) Thiocyanate.
- (vii) *Fluopentammines*, $[\text{Co}(\text{NH}_3)_5\text{F}]\text{X}_2$, are represented by (1) Fluoride; (2) Chloride; (3) Nitrate; and (4) Chromate.
- (viii) *Fluobisethylenediamineammines*, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{F}]\text{X}_2$, include cis- and trans-salts: (1) Fluoride; (2) Perchlorate; (3) Bromide; (4) Dithionate; (5) Nitrate; and (6) Thiocyanate.
- (ix) *Chloropentammines*, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{X}_2$, are the **cobaltic chloropurpureo-salts**. They include (1) Hydroxide; (2) Chloride, and double salts with mercury, antimony, gold, iridium, and platinum chlorides; (3) Chlorite; (4) Chlorate; (5) Perchlorate; (6) Bromide, and double salts with the bromides of mercury, iridium, and platinum; (7) Iodide, the addition compounds with ammonia, and the double salts with mercury and bismuth iodides; (8) Polyiodide; (9) Sulphate; (10) Hydrosulphate; (11) Bromosulphate; (12) Iodosulphate; (13) Thiosulphate; (14) Dithionate; (15) Selenate; (16) Nitrate; (17) Carbonate; (18) Fluosilicate; (19) Pyrophosphate; (20) Hydropyrophosphate; (21) Chromate; (22) Dichromate; (23) Molybdate; (24) Hydrophosphatomolybdate; (25) Tungstates; (26) Tetra-*isothiocyanatodiamminochromate*; (27) Oxalate; (28) Hydro-tartrate; (29) Picrate; (30) Dipicrylamine; (31) 2 : 4 Dinitro- α -naphtholsulphonate; (32) 2 : 4-Dinitro- α -naphtholsulphonate; (33) Naphthalene- α -sulphonate, and other substituted benzene and naphthalenesulphonates.
- (x) *Chlorobisethylenediamineammines*, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Cl}]\text{X}_2$, include cis- and trans-salts: (1) Chloride, and double salts with platinum; (2) Chloroperchlorate; (3) Bromide; (4) Chlorohydrosulphate; (5) Dithionate; (6) Nitrite; (7) Nitrate; (8) Dichromate; and (9) Bromocamphorsulphonate.
- (xi) *Chlorobisethylenediaminehydroxylamines*, $[\text{Co}(\text{NH}_2\text{OH})\text{en}_2\text{Cl}]\text{X}_2$, represented by (1) Chloride, and its double salts with gold and platinum chlorides; (2) Bromide; (3) Nitrate; and (4) Dichromate.
- (xii) *Bromobisethylenediaminehydroxylamines*, $[\text{Co}(\text{NH}_2\text{OH})\text{en}_2\text{Br}]\text{X}_2$, represented by (1) Chloride; (2) Bromide, and its double salt with platinum chloride; (3) Iodide; and (4) Nitrate.
- (xiii) *Chloroethylaminebisethylenediamines*, $[\text{Co en}_2(\text{C}_2\text{H}_5.\text{NH}_2)\text{Cl}]\text{X}_2$, include the chloride and iodide.
- (xiv) *Chloroallylaminebisethylenediamines*, $[\text{Co en}_2(\text{C}_3\text{H}_5.\text{NH}_2)\text{Cl}]\text{X}_2$, include cis- and trans-salts: (1) Chloride; (2) Bromide; (3) Iodide; (4) Dithionate; (5) Nitrate; and (6) Bromocamphorsulphonate.
- (xv) *Chloroanilinebisethylenediamines*, $[\text{Co en}_2(\text{C}_6\text{H}_5\text{NH}_2)\text{Cl}]\text{X}_2$, include (1)

- Chloride; (2) Bromide; (3) Iodide; (4) Chlorodithionate; (5) Nitrate; (6) Chloronitrate; (7) Bromocamphorsulphonate.
- (xvi) *Chloro-p-toluidinebisethylenediamines*, $[\text{Co en}_2(\text{C}_7\text{H}_7\text{NH}_2\text{Cl})\text{X}_2]$, include (1) Chloride; (2) Bromide; (3) Iodide; (4) Dithionate; and (5) Chloronitrate.
- (xvii) *Chlorobenzylaminebisethylenediamines*, $[\text{Co en}_2(\text{C}_7\text{H}_7\text{NH}_2)\text{Cl}]\text{X}_2$, include cis- and trans-salts: (1) Chloride; (2) Bromide; (3) Iodide; (4) Chlorodithionate; (5) Nitrate; and (6) Bromocamphorsulphonate.
- (xviii) *Chloropyridinebisethylenediamines*, $[\text{Co en}_2\text{pyCl}]\text{X}_2$, represented by (1) Chloride, and double salts with zinc, mercuric, stannous, and ferric chlorides; (2) Bromide; (3) Iodide; (4) Sulphate; (5) Nitrate; (6) Phosphate; and (7) Oxalate.
- (xix) *Chloroaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Cl}]\text{X}_2$, include cis-salts: (1) Chloride, and double salts with mercury and platinum chlorides; (2) Bromide; (3) Sulphate; (4) Selenate; (5) Chloroselenate; (6) Nitrate; (7) Fluosilicate; and (8) Chromate.
- (xx) *Chloroaquobisethylenediamines*, $[\text{Co en}_2(\text{H}_2\text{O})\text{Cl}]\text{X}_2$, include some dextro- and lævo-salts: (1) Chloride; (2) Bromide; (3) Sulphate; (4) Dithionate; (5) Selenate; (6) Nitrate; (7) Bromonitrate; (8) Oxalate; and (9) Bromocamphorsulphonate.
- (xxi) *Chlorodiaquotriammines*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_2\text{Cl}]\text{X}_2$, include (1) Chloride; (2) Bromide; (3) Sulphite—violet and grey; (4) Selenate; and (5) Nitrate.
- (xxii) *Chlorodiaquoethylenediamineammines*, $[\text{Co}(\text{NH}_3)\text{en}(\text{H}_2\text{O})_2\text{Cl}]\text{X}_2$, represented by the oxalate.
- (xxiii) *Chlorotriaquodiammines*, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_3\text{Cl}]\text{X}_2$, represented by the sulphate.
- (xxiv) *Bromopentammines*, $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{X}_2$, or the **cobaltic bromopurpureo-salts**, include (1) Hydroxide; (2) Chloride, and double salts with the chlorides of mercury, and platinum; (3) Chlorate; (4) Perchlorate; (5) Bromide, and double salts with mercury, and platinum; (6) Iodide; (7) Sulphate; (8) Hydrosulphate; (9) Bromosulphate; (10) Iodosulphate; (11) Thiosulphate; (12) Dithionate; (13) Nitrate; (14) Fluosilicate; (15) Chromate; (16) Molybdate; (17) Tungstate; (18) Oxalate; (19) Picrate; and (20) Naphthalene- β -sulphonate.
- (xxv) *Bromobisethylenediamineammines*, $[\text{Co}(\text{NH}_3)\text{en}_2\text{Br}]\text{X}_2$, include cis- and trans-salts, and some optically-active forms: (1) Chloride, and the double salt with platinum chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Dithionate; (6) Nitrate; and (7) Bromocamphorsulphonate.
- (xxvi) *Bromohydroxylaminebisethylenediamines*, $[\text{Co}(\text{NH}_2\text{OH})\text{en}_2\text{Br}]\text{X}_2$, represented by (1) Hydroxide; (2) Chloride; (3) Bromide; (4) Iodide; (5) Dithionate; and (6) Nitrate.
- (xxvii) *Bromobisethylenediaminepyridines*, $[\text{Co en}_2\text{pyBr}]\text{X}_2$, represented by the bromide.
- (xxviii) *Bromoquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Br}]\text{X}_2$, represented by the cis-salts: (1) Chloride; (2) Bromide; (3) Sulphate; (4) Bromosulphate; (5) Selenate; and (6) Nitrate.
- (xxix) *Bromoaquobisethylenediamines*, $[\text{Co en}_2(\text{H}_2\text{O})\text{Br}]\text{X}_2$, represented by the cis-salts: (1) Bromide; (2) Nitrite; and (3) Nitrate.
- (xxx) *Iodopentammines*, $[\text{Co}(\text{NH}_3)_5\text{I}]\text{X}_2$, include (1) Chloride; (2) Chlorate; (3) Bromide; (4) Iodide; (5) Sulphate; (6) Nitrate; (7) Picrate; and (8) Dichromate.
- (xxxi) *Nitrosopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{NO})]\text{X}_2$, include (1) Chloride; (2) Iodate; (3) Sulphate; and (4) Nitrate.

- (xxxii) *Dinitrosopentammines*, $[\text{Co}_2(\text{NH}_3)_{10}(\text{N}_2\text{O}_2)]\text{X}_4$, include (1) Chloride; (2) Hydroperchlorate; (3) Bromide; (4) Hydrobromide; (5) Iodide; (6) Hydrobromide; (7) Iodide; (8) Hydroiodate; (9) Sulphate; (10) Hydrosulphate; (11) Nitrate; (12) Hydronitrate; (13) Iodonitrate; (14) Oxalate; (15) Hydroxalate; and (16) Chromate.
- (xxxiii) *Nitropentammines*, $[\text{Co}(\text{NH}_3)_5(\text{NO}_2)]\text{X}_2$. These salts were designated **cobaltic xantho-salts**—from *ξανθός*, yellow—by O. W. Gibbs and F. A. Genth, in allusion to their colour. They include (1) Chloride, and double salts with gold, mercury, and platinum chlorides; (2) Chlorate; (3) Perchlorate; (4) Bromide; (5) Iodide; (6) Sulphate; (7) Hydrosulphate; (8) Iodosulphate; (9) Thiosulphate; (10) Selenate; (11) Nitrite; (12) Hexanitrocobaltate; (13) Tetranitrodiamminocobaltate; (14) Nitrate; (15) Chloronitrate; (16) Bromonitrate; (17) Sulphatonitrate; (18) Amidosulphonate; (19) Imidosulphonate; (20) Hydroxylaminedisulphonate; (21) Hydroxylamineiso-disulphonate; (22) Fluosilicate; (23) Chromate; (24) Dichromate; (25) Molybdate; (26) Tungstate; (27) Oxalate; (28) Picrate; (29) Hexacyanoferroate; and (30) Tetraisothiocyanatodiamminochromate.
- (xxxiv) *Nitritopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{ONO})]\text{X}_2$, the **cobaltic isoxantho-salts** of S. M. Jörgensen, and represented by the chloride.
- (xxxv) *Nitritobisethylenediamineammines*, $[\text{Co}(\text{NH}_3)_2\text{en}_2(\text{NO}_2)]\text{X}_2$, include cis- and trans-salts: (1) Chloride; (2) Bromide; (3) Iodide; (4) Sulphate; (5) Dithionate; (6) Nitrite; (7) Nitrate; (8) Bromonitrate; (9) Thiocyanate; and (10) Bromocamphorsulphonate.
- (xxxvi) *Hydroxyaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{OH})]\text{X}_2$, represented by the hydroxide, and by complexes with the picrate, 2:4-dinitro- α -naphthoxide-7-sulphonate, and picrylamide.
- (xxxvii) *Nitroaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO}_2)]\text{X}_2$, include (1) Hydroxide; (2) Chloride, and double salts with gold, iridium, and platinum chlorides; (3) Bromide and a double salt with iridium bromide; (4) Iodide; (5) Sulphate; (6) Hydrosulphate; (7) Selenate; (8) Hydroselenate; (9) Nitrate; (10) Tetranitrodiamminocobaltate; (11) Carbonate; (12) Oxalate; and (13) Tartrate.
- (xxxviii) *Nitropyridinetriammines*, $[\text{Co}(\text{NH}_3)_3\text{py}_2(\text{NO}_2)]\text{X}_2$, represented by (1) Bromide; (2) Dithionate; and (3) Nitrite.
- (xxxix) *Nitroaquobisethylenediamines*, $[\text{Co en}_2(\text{H}_2\text{O})(\text{NO}_2)]\text{X}_2$, include cis- and trans-salts: (1) Chloride; and (2) Sulphate.
- (xl) *Nitroaquobis trimethylenediamines*, $[\text{Co tr}_2(\text{H}_2\text{O})(\text{NO}_2)]\text{X}_2$, represented by the (1) Bromide; (2) Nitrate; and (3) Thiocyanate.
- (xli) *Dinitritodiaminopentanes*, $[\text{Co ptn}_2(\text{NO}_2)_2]\text{X}$, represented by the nitrate of the α - and β - $\beta\delta$ -diaminopentanes.
- (xlii) *Nitratopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{NO}_3)]\text{X}_2$, are the **cobaltic purpureo-salts**—from *purpura*, purple—of E. Frémy, and now also called **cobaltic nitratopurpureo-salts**. They include (1) Chloride, and the double salts with the chlorides of mercury and platinum; (2) Chlorate; (3) Perchlorate; (4) Bromide; (5) Iodide; (6) Sulphate; (7) Dithionate; (8) Selenate; (9) Nitrate; (10) Hexanitrocobaltate; (11) Tetranitrodiamminocobaltate; (12) Carbonate; (13) Fluosilicate; (14) Chromate; (15) Dichromate; (16) Molybdate; (17) Tungstate; (18) Oxalate; (19) Picrate; and (20) Naphthalene- β -sulphonate.
- (xliii) *Nitratobisethylenediaminammines*, $[\text{Co}(\text{NH}_3)_2\text{en}_2(\text{NO}_3)]\text{X}_2$, include cis- and trans-salts: (1) Bromide; (2) Dithionate; and (3) Nitrate.
- (xliv) *Nitroaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO}_3)]\text{X}_2$, are represented by the nitrate.

- (xlv) *Metaboratopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{BO}_2)]\text{X}_2$, represented by the chloride.
- (xlvi) *Hydrocarbonatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{HCO}_3)]\text{X}_2$, represented by (1) Bromide; (2) Polyiodide; (3) Dithionate; and (4) Nitrate.
- (xlvii) *Cyanoquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Cy}]\text{X}_2$, represented by the chloride.
- (xlviii) *Isothiocyanatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{SCy})]\text{X}_2$, represented by (1) Chloride, and double salts with platinum chlorides; (2) Bromide; (3) Iodide; (4) Sulphate; (5) Selenate; (6) Nitrite; (7) Nitrate; (8) Thiocyanate; (9) Chromate; (10) Molybdate; and (11) Tungstate.
- (xlix) *Isothiocyanatobisethylenediamineammines*, $[\text{Co}(\text{NH}_3)_2(\text{SCy})]\text{X}_2$, include cis- and trans-salts, and dextro- and lævo-salts: (1) Chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Dithionate; (6) Bromodithionate; (7) Nitrite; (8) Nitrate; (9) Thiocyanate; and (10) Chlorodithionate.
 - (l) *Isothiocyanatoaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SCy})]\text{X}_2$, include (1) Chloride; (2) Bromide; (3) Nitrite; and (4) Nitrate.
 - (li) *Isothiocyanatoaquobisethylenediamines*, $[\text{Co en}_2(\text{H}_2\text{O})(\text{SCy})]\text{X}_2$, include cis- and trans-salts: (1) Perchlorate; (2) Bromide; (3) Dithionate; (4) Nitrite; (5) Nitrate; and (6) Thiocyanate.
 - (lii) *Acetatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{C}_2\text{H}_3\text{O}_2)]\text{X}_2$, include (1) Chloride, represented by a double salt with platinous chloride; (2) Iodide; and (3) Nitrate.
 - (liii) *Propionatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{C}_3\text{H}_5\text{O}_2)]\text{X}_2$, represented by the nitrate.
 - (liv) *p-Nitrophenolatoaquobisethylenediamines*, $[\text{Co en}_2(\text{H}_2\text{O})(p\text{-C}_6\text{H}_4\text{O}_3\text{N})]\text{X}_2$, represented by the mono-, di-, and tri-hydrates of the *p*-nitrophenolates, and addition compounds with *p*-nitrophenol.
 - (lv) *Bis-p-Nitrophenolatobisethylenediamines*, $[\text{Co en}_2(p\text{-C}_6\text{H}_5\text{O}_3\text{N-acid})(p\text{-C}_6\text{H}_4\text{O}_3\text{N})]\text{X}_2$, represented by the *p*-nitrophenolate.
 - (lvi) *Bis-o-nitrophenolatobisethylenediamines*, $[\text{Co en}_2(o\text{-C}_6\text{H}_5\text{O}_3\text{N-acid})(o\text{-C}_6\text{H}_4\text{O}_3\text{N})]\text{X}_2$, represented by the *o*-nitrophenolate.
 - (lvii) *Dinitrophenolatoaquobisethylenediamines*, $[\text{Co en}_2(\text{C}_6\text{H}_3\text{O}_5\text{N}_2)]\text{X}_2$, represented by the 2: 4- and the 2: 6-dinitrophenolates, and a basic salt.
 - (lviii) *Picratopentammines*, $\text{Co}(\text{NH}_3)_5(\text{C}_2\text{H}_2\text{O}_7\text{N}_3)]\text{X}_2$, represented by the picrate, and a basic salt.
 - (lix) *Picratoaquobisethylenediamines*, $[\text{Co en}_2(\text{H}_2\text{O})(\text{C}_6\text{H}_2\text{O}_7\text{N}_3)]\text{X}_2$, represented by the picrate.
 - (lx) *Glycinebisethylenediamines*, $[\text{Co en}_2(\text{C}_2\text{H}_4\text{O}_2\text{N})]\text{X}_2$, in which the univalent radicle in the inner complex has a principal and a secondary valency, and represented by some optically-active salts: (1) Chloride, (2) Iodide; (3) Dithionate; and (4) Bromocamphorsulphonate.
 - (lxi) *Sarcosinebisethylenediamines*, $[\text{Co en}_2(\text{C}_3\text{H}_6\text{O}_2\text{N})]\text{X}_2$, represented by the (1) Chloride; (2) Iodide; (3) Dithionate; and (4) Bromocamphorsulphonate.
 - (lxii) *Acetylacetonatobisethylenediamines*, $[\text{Co en}_2(\text{C}_5\text{H}_7\text{O}_2)]\text{X}_2$, represented by some optically-active salts: (1) Chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Sulphate; (6) Persulphate; (7) Nitrate; and (8) Thiocyanate.
 - (lxiii) *Propionylacetonatobisethylenediamines*, $[\text{Co en}_2(\text{COH}_9\text{O}_2)]\text{X}_2$, represented by some optically-active salts: (1) Chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Sulphate; (6) Persulphate; (7) Nitrate; and (8) Thiocyanate.
 - (lxiv) *Pæonolobisethylenediamines*, $[\text{Co en}_2(\text{C}_9\text{H}_9\text{O}_3)]\text{X}_2$, represented by (1) Chlorate; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Dithionate; (6) *d*- and *l*-tartrate.

(lxv) *Benzhydroxamatobisethylenediamines*, $[\text{Co en}_2(\text{C}_7\text{H}_6\text{O}_2\text{N})]\text{X}_2$, represented by (1) Perchlorate; (2) Bromide; (3) Sulphate; (4) Dithionate; and (5) Thiocyanate.

(lxvi) *α -Benzilmonoximebisdiethylenediamine*, $[\text{Co en}_2(\text{C}_{14}\text{H}_{10}\text{O}_2\text{N})]\text{X}_2$, represented by (1) Bromide; and (2) Iodide.

(b) *Pentammines with a Bivalent Radicle in Complex.*

(lxvii) *Sulphitopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{SO}_3)]\text{X}$, represented by (1) Chloride; (2) Hydrochloride; (3) Bromide; (4) Sulphite, and double salts with sodium sulphite; (5) Thiosulphate; and (6) Nitrate.

(lxviii) *Sulphitoaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SO}_3)]\text{X}$, represented by (1) Hydroxide; (2) Sulphite; (3) Cyanide; and (4) Thiocyanate.

(lxix) *Sulphatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{SO}_4)]\text{X}$, or **cobaltic sulphato-pureo-salts**, include (1) Chloride, and the double salt with platinum chloride; (2) Chlorate; (3) Perchlorate; (4) Bromide, and the double salt with iridium bromide; (5) Iodide; (6) Sulphate; (7) Hydrosulphate; (8) Selenate; (9) Nitrate; (10) Carbonate; (11) Fluosilicate; (12) Chromate; (13) Dichromate; and (14) Picrate.

(lxx) *Sulphatoaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SO}_4)]\text{X}$, include (1) Chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Sulphate; (6) Hydro-sulphate; (7) Selenate; and (8) Nitrate.

(lxxi) *Sulphatodiaquotriammines*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_2(\text{SO}_4)]\text{X}$, represented by the sulphate.

(lxxii) *Thiosulphatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{S}_2\text{O}_3)]\text{X}$, include (1) Chloride; (2) Bromide; (3) Iodide; (4) Thiosulphate; (5) Dithionate; (6) Chromate; and (7) Nitrate.

(lxxiii) *Selenitopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{SeO}_3)]\text{X}$, include (1) Chloride; and (2) Selenite.

(lxxiv) *Selenatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{SeO}_4)]\text{X}$, include (1) Chloride, represented by the double salt with platinum chloride; (2) Bromide; (3) Sulphate; (4) Selenate; (5) Hydroselenate; and (6) Nitrate.

(lxxv) *Selenatoaquotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SeO}_4)]\text{X}$, represented by the (1) Chloride; and (2) Sulphate.

(lxxvi) *Carbonatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{CO}_3)]\text{X}$, include (1) Chloride; (2) Bromide; (3) Iodide; (4) Selenate; (5) Nitrate; (6) Oxalate; and (7) Tungstate.

(lxxvii) *Oxalatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{C}_2\text{O}_4)]\text{X}$, include (1) Chloride, represented by the double salt with platinum chloride; (2) Hydrochloride; (3) Bromide; (4) Hydrobromide; (5) Iodide; (6) Hydroiodide; (7) Sulphate; (8) Hydrosulphate; (9) Selenate; (10) Hydroselenate; (11) Nitrate; (12) Hydronitrate; (13) Oxalate; (14) Hydroxalate; and (15) Trioxalatocobaltate.

(lxxviii) *Sulphoacetatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{C}_2\text{H}_2\text{O}_5\text{S})]\text{X}$, represented by the nitrate.

(lxxix) *Mesotartratopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{C}_4\text{H}_4\text{O}_6)]\text{X}$, represented by the nitrate.

(lxxx) *Maleatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{C}_4\text{H}_2\text{O}_4)]\text{X}$, represented by the nitrate.

(lxxxi) *Phthalatopentammines*, $[(\text{Co}(\text{NH}_3)_5(\text{C}_8\text{H}_4\text{O}_4)]\text{X}$, represented by the nitrate.

(lxxxii) *Hydrophosphatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{HPO}_4)]\text{X}$, represented by the hydrophosphate.

(lxxxiii) *Chromatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{CrO}_4)]\text{X}$, include (1) Chloride; (2) Chromate; and (3) Nitrate.

(lxxxiv) *Carbonatobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{CO}_3)]\text{X}_4$, represented by the sulphate.

- (lxxxv) *Malonatobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{C}_3\text{H}_2\text{O}_4)]\text{X}_4$, represented by (1) Nitrate; and (2) Nitratomalonate.
- (lxxxvi) *Glutaratobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{C}_5\text{H}_6\text{O}_4)]\text{X}_4$, represented by (1) Nitrate; and (2) Nitratoglutarate.
- (lxxxvii) *Adipinatobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{C}_6\text{H}_8\text{O}_4)]\text{X}_4$, represented by the nitrate.
- (lxxxviii) *Malatobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{C}_4\text{H}_4\text{O}_5)]\text{X}_4$, represented by (1) Nitrate; and (2) Nitratomalate.
- (lxxxix) *Mesotartatobispentammines*, $[\text{Co}\{(\text{NH}_3)_5\}_2(\text{C}_4\text{H}_4\text{O}_6)]\text{X}_4$, represented by the nitratomesotartate.
- (xc) *Maleatobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{C}_3\text{H}_2\text{O}_4)]\text{X}_4$, represented by the nitrate.
- (xci) *Citraconatobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{C}_5\text{H}_4\text{O}_4)]\text{X}_4$, represented by (1) Nitrate, and (2) Nitratocitraconate.
- (xcii) *Itaconatobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{C}_5\text{H}_4\text{O}_4)]\text{X}_4$, represented by (1) Nitrate; and (2) Nitratocitaconate.
- (xciii) *Phthalatobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{C}_8\text{H}_4\text{O}_2)]\text{X}_4$, represented by the nitrate.
- (xciv) *Methionatobispentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_2(\text{CH}_2\text{O}_6\text{S}_2)]\text{X}_4$, represented by the nitratomethionate.
- (xcv) *Bisdimethylglyoximediamines* including (1) Chloride; (2) Bromide; (3) Iodide; (4) Sulphate; and (5) Thiocyanate.
- (c) *Pentammines with a Tervalent Radicle in Complex.*
- (xcvi) Represented by (1) *Phosphatopentammines*, $[\text{Co}(\text{NH}_3)_5(\text{PO}_4)]2\text{H}_2\text{O}$; (2) *Citratopentammine*, $[\text{Co}(\text{NH}_3)_5(\text{C}_6\text{H}_5\text{O}_7)]2\text{H}_2\text{O}$; and (3) *Hexacyanoferripentammine*, $[\text{Co}(\text{NH}_3)_5(\text{Fe}'''\text{Cy}_6)]$.
- (xcvii) *Hydrocitratotripentammines*, $[\{\text{Co}(\text{NH}_3)_5\}_3(\text{C}_6\text{H}_5\text{O}_7)'''](\text{C}_6\text{H}_7\text{O}_7)_6'$.
- (d) *Pentammines with a Polyvalent Acidic Radicle in Complex.*
- (xcviii) With a quadrivalent radicle represented by (1) *Pyrophosphatopentammines*, $\text{Na}[\text{Co}(\text{NH}_3)_5(\text{P}_2\text{O}_7)]$; and (2) *Hexacyanoferroropentammines*, $\text{K}[\text{Co}(\text{NH}_3)_5(\text{Fe}'''\text{Cy}_6)]$.
- (xcix) With quinequevalent radicle represented by *benzopentacarbonatopentammines*, $\text{Na}_2[\text{Co}(\text{NH}_3)_5\{\text{C}_6\text{H}(\text{CO}_2)_5\}]$.
- (c) With a sexivalent radicle represented by *benzolhexacarbonatopentammines*, $\text{Na}_3[\text{Co}(\text{NH}_3)_5\{\text{C}_6(\text{CO}_2)_6\}]$.

III.—The Tetrammine family, or compounds of the univalent group: $[\text{CoA}_4\text{X}_2]'$.

- (i) *Dihydroxytetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{OH})_2]\text{X}$, represented by the hydroxide and by complexes with the picrate, and picrylamide.
- (ii) *Diffuotetrammines*, $[\text{Co}(\text{NH}_3)_4\text{F}_2]\text{X}$, represented by the chloride.
- (iii) *Diffuobisethylenediamines*, $[\text{Co en}_2\text{F}_2]\text{X}$, represented by cis- and trans-salts: (1) Fluoride; (2) Chloride; (3) Perchlorate; (4) Bromide; (5) Iodide; (6) Dithionate; and (7) Thiocyanate.
- (iv) *Dichlorotetrammines*, $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{X}$, represented by the cis-salts, or **cobaltic violeo-salts**, named by A. Werner—from *viola*, a violet—in allusion to the colour; and trans-salts, or **cobaltic praseo-salts**, named by O. W. Gibbs and F. A. Genth—from *πρασῖος*, leek-green—in allusion to the colour. (1) Fluoride; (2) Chloride, and double salts with mercury, gold, platinum, and iridium chlorides; (3) Chlorate; (4) Bromide; (5) Iodide; (6) Sulphate; (7) Hydro-sulphate, and double salts with silver, and bismuth sulphates; (8) Dithionate; (9) Hydroselenate; (10) Nitrite; (11) Nitrate; (12) Dichromate; (13) Picrate; (14) Thiocyanate; (15) Hexacyanochromate; and (16) Hexacyanoferrate.

- (v) *Dichloroquaterpyridine*, $[\text{Co py}_4\text{Cl}_2]\text{X}$, represented by the trans-salts: (1) Chloride, and its double salts with the chlorides of mercury, gold, and platinum; (2) Bromide; (3) Hydrosulphate; (4) Dithionate; (5) Benzylthiosulphate; (6) Hydroselenate; (7) Nitrate; and (8) Tetranitrodiamminocobaltate.
- (vi) *Dichlorobisethylenediamines*, $[\text{Co en}_2\text{Cl}_2]\text{X}$, represented by cis- or **violet**-salts, and trans- or **praseo**-salts, as well as by optically-active forms: (1) Hydroxide; (2) Chloride, as well as ammonia addition compounds, and double salts with the chlorides of copper, cadmium, mercury, stannous and stannic tin, bismuth, antimony, iridium, and platinum; (3) Hydrochloride; (4) Bromide, and a double salt with cadmium bromide; (5) Iodide, and a double salt with cadmium, and mercury iodides; (6) Sulphate; (7) Hydrosulphate; (8) Dithionate; (9) Nitrite; (10) Nitrate; (11) Thiocyanate; (12) Monochloroacetate; (13) Dichloroacetate; (14) Dibromoacetate; (15) Oxalate; (16) Malonate; (17) Methylmalonate; (18) Ethylmalonate; (19) Chloromalonate; (20) Bromomalonate; (21) Succinate; (22) Dibromosuccinate; (23) Glutarate; (24) Adipate; (25) Tartrate; (26) Mesotartrate; (27) Malleate; (28) Fumarate; (29) Citraconate; (30) Mesaconate; (31) Itaconate; (32) Acetodicarbonate; (33) Phthalate; (34) Thiodiacetate; (35) Dithiodiacetate; (36) Dithiodilactate; (37) Thiodilactate; (38) Sulphonyldiacetate; (39) Sulphoacetate; (40) Sulphobenzoate; (41) Benzylsulphoacetate; and (42) Methionate.
- (vii) *Dichlorobispropylenediamines*, $[\text{Co pn}_2\text{Cl}_2]\text{X}$, include cis- and trans-salts: (1) Chloride, and double salts with mercury, gold, and platinum chlorides; (2) Hydrochloride; (3) Bromide; (4) Sulphate; (5) Hydrosulphate; (6) Dithionate; (7) Nitrate; (8) Permanganate; (9) Thiocyanate; and (10) Hexacyanoferrate.
- (viii) *Dichlorobis(trimethylenediamines)*, $[\text{Co}\{\text{NH}_2(\text{CH}_2)_3\text{NH}_2\}_2\text{Cl}_2]\text{X}$, is represented by the trans-chloride, and its double salt with platinum chloride.
- (ix) *Dichlorobiscyclopentanediamines*, $[\text{Co}(\text{C}_5\text{H}_{12}\text{N}_2)_2\text{Cl}_2]\text{X}$, are represented by the cis- and trans-chloride.
- (x) *Dichlorobispyridinediammines*, $[\text{Co}(\text{NH}_3)_2\text{py}_2\text{Cl}_2]\text{X}$, are represented by (1) Chloride; and (2) Nitrate.
- (xi) *Dichlorobisethylenediaminediammines*, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Cl}_2]\text{X}$, is represented by cis- and trans-salts: (1) Chloride; (2) Bromide; (3) Iodide; (4) Hydrosulphate; (5) Dithionate; (6) Nitrate; and (7) Thiocyanate.
- (xii) *Dichlorodiaminopentanes*, $[\text{Co ptn}_2\text{Cl}_2]\text{X}$, represented by the chloride of $\alpha\beta\delta$ - and $\beta\beta\delta$ -diaminopentanes.
- (xiii) *Dichloroaquotriammines*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{Cl}_2]\text{X}$, were called by F. Rose, **cobaltic dichro-salts**—from $\delta\acute{\iota}\chi\rho\omega\mu\omicron\varsigma$, two-coloured—in allusion to the dichroism of the salts. The series include (1) Chloride—grey, and greyish-green forms; (2) Sulphate; (3) Hydrosulphate; (4) Nitrate; and (5) Tetranitrodiamminocobaltate.
- (xiv) *Dichloroaquoethylenediamineammines*, $[\text{Co}(\text{NH}_3)\text{en}(\text{H}_2\text{O})\text{Cl}_2]\text{X}$, represented by the trans-salts: (1) Chloride; and (2) Nitrate.
- (xv) *Dichlorodiaquodiammines*, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_2\text{Cl}_2]\text{X}$, include (1) Chloride—green, and blue forms; (2) Hydrosulphate; (3) Hydroselenate; and (4) Nitrate.
- (xvi) *Dibromotetrammines*, $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{X}$, include the trans- or praseo-salts: (1) Chloride, and its double salt with platinum chloride; (2) Bromide, and its double salts with mercury and platinum bromides; (3) Hydrobromide; (4) Iodide; (5) Dithionate; (6) Nitrate; (7) Thiocyanate; and (8) Hydrothiodiacetate.

- (xvii) *Dibromobis(trimethylenediamines)*, $[\text{Co tr}_2\text{Br}_2]\text{X}$, represented by the bromide.
- (xviii) *Dibromo-aquobis(ethylenediamine)ammines*, $[\text{Co}(\text{NH}_3)\text{en}(\text{H}_2\text{O})\text{Br}_2]\text{X}$, represented by the bromide.
- (xix) *Dihydroselenatotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{HSeO}_4)_2]\text{X}$, represented by the selenate.
- (xx) *Dinitrotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)_2]\text{X}$, S. M. Jørgensen named the cis-salts the **cobaltic flavo-salts**—from *flavus*, yellow—in allusion to the colour. O. W. Gibbs called the trans-salts—**cobaltic croceo-salts**—from *croceus*, saffron-red—in allusion to the colour: (1) Hydroxide; (2) Chloride, and double salts with the chlorides of gold, cadmium, mercury, platinum, and iridium; (3) Chlorate; (4) Perchlorate; (5) Bromide, with its ammonia addition compounds, and double salts with cadmium, mercury, and iridium bromides; (6) Iodide, and double salts with mercury, and bismuth iodides; (7) Polyiodide; (8) Sulphate; (9) Selenate; (10) Nitrite; (11) Nitrate, and double salts with potassium, and rubidium nitrates; (12) Hydronitrate; (13) Hexanitrocobaltate; (14) Tetranitrodiammincobaltate; (14) Amidosulphonate; (15) Hydroxylaminesulphonate; (16) Fluosilicate; (17) Chromate; (18) Dichromate; (19) Molybdate; (20) Tetraisoithiocyanatodiammincobaltate; (21) Picrate; and (22) Naphthalene- β -sulphonate.
- (xxi) *Dinitrobis(ethylenediamines)*, $[\text{Co en}_2(\text{NO}_2)_2]\text{X}$, include cis- or flavo-salts, and trans- or croceo-salts, as well as optically-active forms: (1) Hydroxide; (2) Chloride, and double salts with the chlorides of platinum; (3) Perchlorate; (4) Bromide; (5) Iodide; (6) Sulphate; (7) Hydrosulphate; (8) Nitrite; (9) Nitrate; (10) Thiocyanate; (11) Camphorsulphonate; and (12) Bromocamphorsulphonate.
- (xxii) *Dinitrobis(trimethylenediamines)*, $[\text{Co}\{\text{NH}_2(\text{CH}_2)_3\text{NH}_2\}_2(\text{NO}_2)_2]\text{X}$, with the trans-salts: (1) Chloride; (2) Bromide; (3) Iodide; (4) Nitrite; and (5) Nitrate.
- (xxiii) *Dinitrobis(pyridinediammines)*, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{NO}_2)_2]\text{X}$, and the trans-salts: (1) Bromide; (2) Dithionate; and (3) Nitrate.
- (xxiv) *Dinitropropylenediaminethylenediamines*, $[\text{Co en pn}(\text{NO}_2)_2]\text{X}$, represented by cis- or flavo-salts, and trans- or croceo-salts, as well as by active forms: (1) Chloride; (2) Bromide; (3) Sulphate; (4) Nitrite; (5) Thiocyanate; and (6) Bromocamphorsulphonate.
- (xxv) *Dinitro-aquotriammines*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})(\text{NO}_2)_2]\text{X}$, represented by the hydroxide.
- (xxvi) *Dinitrobis(ethylenediamines)*, $[\text{Co en}_2(\text{ONO})_2]\text{X}$, represented by cis- and trans-salts: (1) Chloride; (2) Bromide; (3) Iodide; (4) Dithionate; (5) Nitrate; and (6) Thiocyanate.
- (xxvii) *Dinitrobis(pyridinediammines)*, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{ONO})_2]\text{X}$, represented by the trans-salts: (1) Bromide; (2) Iodide; (3) Dithionate; (4) Iodide; (5) Nitrate; and (6) Dithionate.
- (xxviii) *Dinitratotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{NO}_3)_2]\text{X}$, represented by the nitrate.
- (xxix) *Dinitratobis(ethylenediamines)*, $[\text{Co en}_2(\text{NO}_3)_2]\text{X}$, represented by (1) Bromide; (2) Nitrate; and (3) Hydronitrate.
- (xxx) *Nitratonitrobis(trimethylenediamine)*, $[\text{Co tr}_2(\text{NO}_2)(\text{NO}_3)]\text{X}$, represented by the nitrate.
- (xxxi) *Bissalicylatobis(ethylenediamines)*, $[\text{Co en}_2(\text{C}_7\text{H}_5\text{O}_3)_2]\text{X}$, represented by the salicylate.
- (xxxii) *Bisnitrophenolatobis(ethylenediamines)*, $[\text{Co en}_2(\text{C}_6\text{H}_4\text{O}_3\text{N})_2]\text{X}$, represented by the *m*- and *p*-nitrophenolates, and a double salt with sodium *m*-nitrophenolate.

- (xxxiii) *Dithiocyanatotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{SCy})_2]\text{X}$, represented by the iodide.
- (xxxiv) *Dithiocyanatotriaminotriethylamine*, $[\text{Co}(\text{NH}_3)_3\{(\text{C}_2\text{H}_5)_3\text{N}\}(\text{SCy})_2]\text{X}$, represented by (1) Chloride, and its double salt with platinum; (2) Nitrate; and (3) Thiocyanate.
- (xxxv) *Diisothiocyanatobisethylenediamines*, $[\text{Co en}_2(\text{SCy})_2]\text{X}$, includes cis- and trans-salts: (1) Chloride; (2) Bromide; (3) Iodide; (4) Sulphate; (5) Hydrosulphate; (6) Dithionate; (7) Hydroselenate; (8) Nitrate; and (9) Thiocyanate.
- (xxxvi) *Diisothiocyanatobispropylenediamines*, $[\text{Co pn}_2(\text{SCy})_2]\text{X}$, include (1) Chloride; (2) Bromide; (3) Iodide; and (4) Thiocyanate.
- (xxxvii) *Nitrohydroxytetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{OH})(\text{NO}_2)]\text{X}$, include (1) Chloride; (2) Bromide; (3) Iodide; and (4) Nitrate.
- (xxxviii) *Nitratonitrobisethylenediamines*, $[\text{Co en}_2(\text{NO}_2)(\text{NO}_3)]\text{X}$, represented by the trans-nitrate, and hydronitrate.
- (xxxix) *Fluohydroxytetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{OH})\text{F}]\text{X}$, represented by the nitrate.
- (xl) *Chlorohydroxytetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{OH})\text{Cl}]\text{X}$, represented by the dithionate.
- (xli) *Chlorohydroxybisethylenediamines*, $[\text{Co en}_2(\text{OH})\text{Cl}]\text{X}$, include cis- and trans-salts, and optically-active salts: (1) Chloride; (2) Bromide; and (3) Nitrate.
- (xlii) *Chloronitrotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)\text{Cl}]\text{X}$, include (1) Chloride; (2) Bromide; (3) Iodide; (4) Nitrate; (5) Dichlorodinitrodiamminocobaltate; and (6) Thiocyanate.
- (xliii) *Chloronitrobisethylenediamines*, $[\text{Co en}_2(\text{NO}_2)\text{Cl}]\text{X}$, include cis- and trans-salts, as well as optically-active salts: (1) Chloride; (2) Bromide; (3) Iodide; (4) Hydrosulphate; (5) Nitrite; (6) Nitrate; (7) Hydronitrate; (8) Thiocyanate; (9) Camphorsulphonate; and (10) Bromocamphorsulphonate.
- (xliv) *Chloronitrobispyridinediammines*, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{NO}_2)\text{Cl}]\text{X}$, represented by the nitrate.
- (xlv) *Bromohydroxybisethylenediamines*, $[\text{Co en}_2(\text{OH})\text{Br}]\text{X}$, represented by the bromide.
- (xlvi) *Bromonitrobisethylenediamines*, $[\text{Co en}_2(\text{NO}_2)\text{Br}]\text{X}$, represented by the (1) Iodide; (2) Nitrite; and (3) Nitrate.
- (xlvii) *Bromonitrotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)\text{Br}]\text{X}$, represented the bromide.
- (xlviii) *Bromonitrobisethylenediamines*, $[\text{Co en}_2(\text{NO}_2)\text{Br}]\text{X}$, represented by (1) Chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Sulphate; (6) Persulphate; (7) Dithionate; (8) Nitrite; (9) Nitrate; (10) Thiocyanate; and (11) Camphorsulphonate.
- (xlix) *Bromochlorobisethylenediamines*, $[\text{Co en}_2\text{ClBr}]\text{X}$, represented by cis- and trans-salts, and some optically-active forms: (1) Chloride; (2) Bromide; (3) Sulphate; (4) Dithionate; (5) Nitrate; (6) Thiocyanate; and (7) Bromocamphorsulphonate.
- (l) *Bromochloroaquotriammines*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{ClBr}]\text{X}$, represented by the bromide.
- (li) *Bromochloroaquoethylenediamineammines*, $[\text{Co}(\text{NH}_3)\text{en}(\text{H}_2\text{O})\text{ClBr}]\text{X}$, represented by the bromide.
- (lii) *Hydrocarbonatonitrotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)(\text{HCO}_3)]\text{X}$, represented by the nitrate.
- (liii) *Isouthiocyanatohydroxybisethylenediamines*, $[\text{Co en}_2(\text{OH})(\text{SCy})]\text{X}$, represented by cis- and trans-thiocyanate.
- (liv) *Isouthiocyanatonitrotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)(\text{SCy})]\text{X}$, include (1) Hydroxide; (2) Chloride, and its double salt with silver and mer-

- cury; (3) Bromide; (4) Iodide; (5) Polyiodide; (6) Nitrite; (7) Nitrate; and (8) Oxalatodinitrodiammine.
- (lv) *Isothiocyanatonitrobisethylenediamines*, $[\text{Co en}_2(\text{NO}_2)(\text{SCy})]\text{X}$, represented by cis- and trans-salts, and some optically-active forms: (1) Chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Sulphate; (6) Dithionate; (7) Nitrite; (8) Nitrate; and (9) Thiocyanate.
- (lvi) *Isothiocyanatonitritobisethylenediamines*, $[\text{Co en}_2(\text{ONO})(\text{SCy})]\text{X}$, represented by (1) Nitrate; and (2) Thiocyanate.
- (lvii) *Isothiocyanatochlorobisethylenediamines*, $[\text{Co en}_2\text{Cl}(\text{SCy})]\text{X}$, include cis- and trans-salts, and some optically-active forms: (1) Chloride; (2) Perchlorate; (3) Bromide; (4) Iodide; (5) Sulphate; (6) Dithionate; (7) Nitrite; (8) Nitrate; (9) Dichromate; (10) Thiocyanate; and (11) Bromocamphorsulphonate.
- (lviii) *Isothiocyanatobromobisethylenediamines*, $[\text{Co en}_2\text{Br}(\text{SCy})]\text{X}$, represented by cis- and trans-salts: (1) Perchlorate; (2) Bromide; (3) Sulphate; (4) Dithionate; (5) Nitrate; and (6) Thiocyanate.
- (lix) *Bisdimethylglyoximedianamines*, $[\text{Co}(\text{NH}_3)_2\{\text{CH}_3\text{C}(\text{NO})\text{C}(\text{NO})\text{CH}_3\}_2]\text{X}$, represented by (1) Hydroxide; (2) Chloride; (3) Bromide; (4) Iodide; (5) Sulphate; (6) Selenate; (7) Nitrite; (8) Nitrate; and (9) Picrate.
- (lx) *Bisdimethylglyoximenebis-hydroxylamines*, $[\text{Co}(\text{NH}_2\text{OH})_2\{\text{CH}_3\text{C}(\text{NO})\text{C}(\text{NOH})\text{CH}_3\}_2]\text{X}$, include (1) Chloride; and (2) Iodide.
- (lxi) *Bisdimethylglyoximinbisethylamines*, $[\text{Co}(\text{C}_2\text{H}_5\text{NH}_2)_2\{\text{CH}_3\text{C}(\text{NO})\text{C}(\text{NOH})\text{CH}_3\}_2]\text{X}$, include (1) Hydroxide; (2) Chloride; (3) Iodide; and (4) Nitrate.
- (lxii) *Bisdimethylglyoximebis-anilines*, $[\text{Co}(\text{C}_6\text{H}_5\text{NH}_2)_2\{\text{CH}_3\text{C}(\text{NO})\text{C}(\text{NOH})\text{CH}_3\}_2]\text{X}$, salts are known.
- (lxiii) *Bisdimethylglyoximebis-p-toluidines*, $[\text{Co}(\text{C}_7\text{H}_7\text{NH}_2)_2\{\text{CH}_3\text{C}(\text{NO})\text{C}(\text{NOH})\text{CH}_3\}_2]\text{X}$, salts are known.
- (lxiv) *Bisdimethylglyoximebispyridines*, $[\text{Co py}_2\{\text{CH}_3\text{C}(\text{NO})\text{C}(\text{NOH})\text{CH}_3\}_2]\text{X}$, include (1) Hydroxide; (2) Chloride; (3) Iodide; (4) Nitrate; and (5) Thiocyanate.
- (lxv) *Bismonomethylglyoximinediammines*, $[\text{Co}(\text{NH}_3)_2\{\text{CH}_3\text{C}(\text{NO})\text{C}(\text{NOH})\text{H}\}_2]\text{X}$, represented by (1) Hydroxide; (2) Chloride; and (3) Iodide.
- (lxvi) *Sulphitobisethylenediamines*, $[\text{Co en}_2(\text{SO}_3)]\text{X}$, include (1) Chloride, and the double salts with gold, and platinum; (2) Bromide; and (3) Thiocyanate.
- (lxvii) *Sulphitaquotriammines*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})(\text{SO}_3)]\text{X}$, represented by the sulphite.
- (lxviii) *Sulphatobisethylenediamines*, $[\text{Co en}_2(\text{SO}_4)]\text{X}$, represented by the bromide.
- (lxix) *Thiosulphatobisethylenediamines*, $[\text{Co en}_2(\text{S}_2\text{O}_3)]\text{X}$, represented by the bromide.
- (lxx) *Carbonatotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{X}$, include (1) Hydroxide; (2) Fluoride; (3) Chloride, and the double salts with the chlorides of gold, and platinum; (4) Perchlorate; (5) Bromide, and a double salt with iridium bromide; (6) Iodide, and the double salts with mercury, and bismuth iodides; (7) Polyiodide; (8) Hydrosulphate; (9) Sulphate; (10) Dithionate; (11) Selenate; (12) Nitrate; (13) Carbonate; (14) Hydrocarbonate; (15) Chromate; (16) Dichromate; (17) Molybdate; (18) Tungstate; (19) Oxalate; (20) Trioxalato-cobaltate; (21) Malonate; and (22) Picrate.
- (lxxi) *Carbonatobisethylenediamines*, $[\text{Co en}_2(\text{CO}_3)]\text{X}$, include optically-active forms: (1) Hydroxide; (2) Chloride; (3) Bromide; (4) Iodide, and the double salts with silver, and mercury iodides; (5) Sulphate; (6) Dithionate; (7) Nitrate; and (8) Thiocyanate.

- (lxxii) *Carbonatobispropylenediamines*, $[\text{Co pn}_2(\text{CO}_3)]\text{X}$, represented by (1) Chloride; and (2) Nitrate.
- (lxxiii) *Carbonatobis(trimethylenediamines)*, $[\text{Co}\{\text{NH}_2(\text{CH}_2)_3\text{NH}_2\}_2(\text{CO}_3)]\text{X}$, represented by the chloride.
- (lxxiv) *Carbonatobisdiaminopentanes*, $[\text{Co ptn}_2\text{CO}_3]\text{X}$, represented by the chloride of the $\alpha\beta\delta$ - and $\beta\beta\delta$ -diaminopentanes.
- (lxxv) *Oxalatotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{C}_2\text{O}_4)]\text{X}$, include (1) Hydroxide; (2) Chloride, and double salts with the platinum chlorides; (3) Chlorate; (4) Perchlorate; (5) Bromide; (6) Sulphate; (7) Perchlorate; (8) Dithionate; (9) Selenate; (10) Nitrate; (11) Chromate; (12) Dichromate; (13) Oxalate; (14) Hydroxalate; (15) Trioxalatocobaltate; (16) Dioxalatodiamminocobaltate; (17) Oxalatodinitrodiamminocobaltate; and (18) Thiocyanatochromate.
- (lxxvi) *Oxalatobisethylenediamines*, $[\text{Co en}_2(\text{C}_2\text{O}_4)]\text{X}$, represented by some optically-active forms: (1) Hydroxide; (2) Chloride, and a double salt with gold chloride; (3) Perchlorate; (4) Bromide; (5) Iodide; (6) Sulphate; (7) Hydrosulphate; (8) Dithionate; (9) Selenate; (10) Nitrate; (11) Thiocyanate; (12) Dioxalatobisethylenediaminechromate; (13) Molybdate; and (14) Tungstate.
- (lxxvii) *Oxalatoaquotriammines*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})(\text{C}_2\text{O}_4)]\text{X}$, include (1) Chloride; (2) Bromide; (3) Sulphate; (4) Dithionate; and (5) Nitrate.
- (lxxviii) *Oxalatobisdiaminopentanes*, $[\text{Co ptn}_2(\text{C}_2\text{O}_4)]\text{X}$, represented by the (1) Chloride; and the (2) Oxalate of the $\alpha\beta\delta$ - and $\beta\beta\delta$ -diaminopentanes.
- (lxxix) *Malonatotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{C}_3\text{H}_2\text{O}_4)]\text{X}$, represented by (1) Chloride, and a double salt with gold chloride; (2) Bromide; (3) Sulphate; (4) Dithionate; (5) Selenate; (6) Nitrate; (7) Thiocyanate; and (8) Hydromalonate.
- (lxxx) *Dimethylmalonatobisethylenediamines*, $[\text{Co en}_2(\text{C}_5\text{H}_6\text{O}_4)]\text{X}$, include (1) Chloride; (2) Bromide; and (3) Nitrate.
- (lxxx i) *Succinatobisethylenediamines*, $[\text{Co en}_2(\text{C}_4\text{H}_4\text{O}_4)]\text{X}$, include (1) Bromide; (2) Nitrate; and (3) Hydrosuccinate.
- (lxxxii) *Dibromosuccinatobisethylenediamines*, $[\text{Co en}_2(\text{C}_4\text{H}_2\text{O}_4\text{BrX}_2)]\text{X}$, include (1) Bromide; (2) Nitrate; and (3) Dibromosuccinate.
- (lxxxiii) *Mesotartratobisethylenediamines*, $[\text{Co en}_2(\text{C}_4\text{H}_4\text{O}_6)]\text{X}$, include (1) Bromide; and (2) Hydromesotartrate.
- (lxxxiv) *Maleinatobisethylenediamines*, $[\text{Co en}_2(\text{C}_4\text{H}_2\text{O}_4)]\text{X}$, include (1) Bromide; (2) Nitrate; and (3) Hydromaleinate.
- (lxxxv) *Citraconatobisethylenediamines*, $[\text{Co en}_2(\text{C}_5\text{H}_4\text{O}_4)]\text{X}$, represented by the hydrocitraconate.
- (lxxxvi) *Itaconatobisethylenediamines*, $[\text{Co en}_2(\text{C}_5\text{H}_4\text{O}_4)]\text{X}$, represented by the hydroitaconate.
- (lxxxvii) *Phthalatobisethylenediamines*, $[\text{Co en}_2(\text{C}_8\text{H}_4\text{O}_4)]\text{X}$, include (1) Bromide; (2) Nitrate; and (3) Hydrophthalate.
- (lxxxviii) *Homophthalatobisethylenediamines*, $[\text{Co en}_2(\text{C}_9\text{H}_6\text{O}_4)]\text{X}$, include (1) Bromide; (2) Thiocyanate; and (3) Hydrohomophthalate.
- (lxxxix) *Salicylatotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{C}_7\text{H}_4\text{O}_3)]\text{X}$, include (1) Chloride, and the double salt with platinum chloride; (2) Hydrochloride; (3) Hydroperchlorate; (4) Bromide; (5) Hydrobromide; (6) Iodide; (7) Hydroiodide; (8) Iodate; (9) Hydrosulphite; (10) Sulphate; (11) Hydrosulphate; (12) Thiosulphate; (13) Dithionate; (14) Hydrodithionate; (15) Tetrathionate; (16) Hydrotetrathionate; (17) Hydroselenite; (18) Nitrite; (19) Nitrate; (20) Hydronitrate; (21) Tetranitrodiamminocobaltate; (22) Carbonate; (23) Hydrocarbonate; (24) Fluosilicate; (25) Hydrofluosilicate; (26) Phosphite; (27) Hydrophosphate; (28) Pyrophosphate; (29) Hydropyrophosphate; (30) Hydropyroantimonate; (31) Hexacyanocobaltate;

- (32) Oxalate; (33) Hydroxalate; (34) Mesoxalate; (35) Dioxytartrate; (36) Picrate; and (37) α -Naphthylamine- γ -sulphonate.
- (xc) *Salicyatobisethylenediamines*, $[\text{Co en}_2(\text{C}_7\text{H}_4\text{O}_3)]\text{X}$, include (1) Chloride, and a double salt with mercury chloride; (2) Hydrochloride; (3) Bromide, and mercury bromide double salt; (4) Iodide, and mercury iodide double salt; (5) Nitrate; (6) Hydronitrate; (7) Carbonate; (8) Hydrocarbonate; and (9) Camphorsulphonate.
- (xci) *Sulphoacetatobisethylenediamines*, $[\text{Co en}_2(\text{C}_2\text{H}_2\text{O}_5\text{S})]\text{X}$, include (1) Chloride, and platinum chloride double salt; (2) Bromide; (3) Nitrate; (4) Thiocyanate; and (5) Hydrosulphoacetate.
- (xcii) *Benzylsulphoacetatobisethylenediamines*, $[\text{Co en}_2(\text{C}_9\text{H}_8\text{O}_5\text{S})]\text{X}$, include (1) Bromide; and (2) Benzylsulphoacetate.
- (xciii) *o-Sulphobenzoatobisethylenediamines*, $[\text{Co en}_2(\text{C}_7\text{H}_4\text{O}_5\text{S})]\text{X}$, include (1) Bromide; and (2) Hydrosulphobenzoate.
- (xciv) *Sulphonyldiacetatobisethylenediamines*, $[\text{Co en}_2(\text{C}_4\text{H}_4\text{O}_6\text{S})]\text{X}$, include (1) Chloride, and double salts with gold, and platinum chlorides; (2) Bromide; (3) Iodide; (4) Dithionate; (5) Nitrate; (6) Thiocyanate; (7) Hydrosulphonyldiacetate.
- (xcv) *Methionatobisethylenediamines*, $[\text{Co en}_2(\text{CH}_2\text{O}_6\text{S}_2)]\text{X}$, include (1) Chloride, and platinum chloride double salt; (2) Bromide; (3) Nitrate; (4) Thiocyanate; and (5) Methionate.
- (xcvi) *Bromobenzene-3 : 4-disulphonatobisethylenediamines*, $[\text{Co en}_2(\text{C}_6\text{H}_3\text{O}_6\text{BrS}_2)]\text{X}$, represented by the Bromobenzene-3 : 4-disulphonate.
- (xcvii) *Ethylenediaminediacetylacetonatodiammines*, $[\text{Co}(\text{NH}_3)_2(\text{C}_{18}\text{H}_{12}\text{N}_2\text{O}_2)]\text{X}$, include (1) Chloride; (2) Chlorate; (3) Perchlorate; (4) Bromide; (5) Iodide; (6) Nitrite; (7) Nitrate; and (8) Camphorsulphonate.
- (xcviii) *Chromatotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{CrO}_4)]\text{X}$, include (1) Nitrate; (2) Chromate; and (3) Dichromate.
- (xcix) *Chromatoaquotriammines*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})(\text{CrO}_4)]\text{X}$, are represented by the dichromate.
- (c) *Molybdatotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{MoO}_4)]\text{X}$, include (1) Nitrate; (2) Molybdate; and (3) Trimolybdate.
- (ci) *Dimolybdatotetrammines*, $[\text{Co}(\text{NH}_3)_4(\text{Mo}_2\text{O}_7)]\text{X}$, are represented by the trimolybdate.
- (cii) *Phosphatotetrammine*, $[\text{Co}(\text{NH}_3)_4(\text{PO}_4)]$.
- (ciii) *Trischromatobistetrammines*, $[\{\text{Co}(\text{NH}_3)_4\}_2(\text{CrO}_4)_3]$.
- (civ) *Sulphitohydroxytetrammine*, $[\text{Co}(\text{NH}_3)_4(\text{OH})(\text{SO}_3)]$.
- (cv) *Sulphitonitrotetrammine*, $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)(\text{SO}_3)]$.
- (cvi) *Oxalatochloro-aquotriammine*, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{Cl}(\text{C}_2\text{O}_4)]$.
- (cvii) *Disulphitotetrammines*, $\text{M}[\text{Co}(\text{NH}_3)_4(\text{SO}_3)_2]$, include cis- and trans-salts: (1) Lithium; (2) Sodium; (3) Ammonium, and double salts with ammonium and barium sulphites; (4) Potassium; (5) Rubidium; (6) Cæsium; (7) Barium; (8) Cobaltous; and (9) Cobaltic salts.
- (cviii) *Disulphitobisethylenediamines*, $\text{M}[\text{Co en}_2(\text{SO}_3)_2]$, include (1) Sodium; (2) Ammonium; and (3) Strychnine salts.
- (cix) *Disulphitoethylenediaminediammines*, $\text{M}[\text{Co}(\text{NH}_3)_2\text{en}(\text{SO}_3)_2]$, represented by the ammonium salt.
- (cx) *Disulphitobispropylenediamines*, $\text{M}[\text{Co pn}_2(\text{SO}_3)_2]$, represented by the ammonium salt.
- (cxi) *Disulphito-aquotriammines*, $\text{M}[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})(\text{SO}_3)_2]$, represented by (1) Hydrogen salt, *i.e.* the acid, and (2) Sodium salt.
- (cxii) *Bischromatotetrammines*, $\text{M}[\text{Co}(\text{NH}_3)_4(\text{CrO}_4)_2]$, include (1) Lithium; (2) Sodium; (3) Potassium; and (4) Magnesium salts.
- (cxiii) *Bisdimethylglyoximedianine*, including the (1) Chloride; (2) Bromide; (3) Iodide; (4) Sulphate; and (5) Thiocyanate.

IV.—**The triammine family**, or compounds of the null-valent group, which, with a simple univalent acidic radicle, X' , can be symbolized, $[CoA_3X_3']$. There are further complications with the introduction of a bivalent radicle, Y'' , and only a few types have been investigated.

- (i) *Compounds of the type* $[CoA_3X_3']$, include (1) Trinitrotriammine; (2) Trinitroethylenediamineammine; (3) Trinitropropylenediamineammine; (4) Trinitratotriammine; (5) Trichlorotriammine; (6) Tribromotriammine; (7) Chlorodinitrotriammine; (8) Bromodinitrotriammine; and (9) Dihydroxytetranitrotrihydrazine. There is also a series of complexes built up with (1) Dimethylglyoxime, $CH_3C(NO)(OH)CH_3$; and also series with (2) Monomethylglyoxime, $HC(NO)(OH)CH_3$; with (3) Methyl ethylglyoxime, $CH_3C(NO)(OH)C(NO)C_2H_5$; with (4) α - and β -benzilmonoximes, $C_6H_5.C(NO).CO.C_6H_5$; with (5) Glycine, NH_2CH_2CO ; with (6) alanine, $CH_3.CH(NH_2).COOH$; with (7) Methylalanine, $CH_3.CH(NH_2).COOCH_3$; with (8) Picolonic acid, $C_5H_4N(COOH)$; with (9) Dithiocarbamate, $NH_2.CS_2H$; with (10) Dimethyldithiocarbamate, $N(CH_3)_2.CS_2H$; with (11) Di-*iso*-butyldithiocarbamate, $N(C_4H_9)_2CS_2H$; (12) Phenyldithiocarbamate, $NH(C_6H_5).CS_2H$; (13) with 2:2'-pyridylpyrrole, $(CH_3CH_2)_2N.C_5H_4N$; (14) with pyrrole-2-methylimide, $C_4H_4.N.CH:NCH_3$; (15) with 2-pyridylmethylketoxime, $(C_4H_4N.CH)(NO)C_4H_3$; and with (16) Diazoaminotoluene, $C_7H_7.N_2.NH.C_7H_7$.
- (ii) *Compounds of the type*, $[(CoA_3)_2Y_3'']$, include (1) Sulphodithiocarbonatohexammine, $[Co(NH_3)_3)_2(CS_3)_2S]$; (2) Thiosulphatodithiocarbonatohexammine, $[Co(NH_3)_3)_2(CS_3)_2(S_2O_3)]$; (3) Tricarbonatohexammine, $[Co(NH_3)_3)_2(CO_3)_3]$; (4) Trioxalatobisethylenediaminediammine, $[Co(NH_3)_3)_2(en)_2(C_2O_4)_3]$; and (5) Trirubeanatotetraquodiammine, $[Co(NH_3)(H_2O)_2)_2(C_2N_2S_2H_2)_3]$.
- (iii) *Compounds of the type*, $[CoA_3Y''X']$, include (1) Hydroxychromatotriammine, $[Co(NH_3)_3(CrO_4)(OH)]$; (2) Hydrosulphothiocarbonatotriammine, $[Co(NH_3)_3(CS_3)(HS)]$; (3) Isothiocyanatolatotriammine, $[Co(NH_3)_3(C_2O_4)(SCy)]$; (4) Hydroxyoxalatotriammine, $[Co(NH_3)_3(C_2O_4)(OH)]$; (5) Nitroxalatotriammine, $[Co(NH_3)_3(C_2O_4)(NO_2)]$; and (6) Chloroxalatotriammine, $[Co(NH_3)_3(C_2O_4)Cl]$.
- (iv) *Compounds of the type* $[(CoA_3)_2Y''X_4']$, include (1) Tetranitrosulphatohexammine, $[Co(NH_3)_3)_2(SO_4)(NO_2)_4]$; and (2) Tetranitroselenatohexammine, $[Co(NH_3)_3)_2(SeO_4)(NO_2)_4]$.
- (v) *Compounds of the type*, $M[CoA_3Y_2'']$, include Dioxalatotriaminocobaltic acid, $H[Co(NH_3)_3(C_2O_4)_2].2H_2O$, and the sodium, ammonium, potassium, pyridine, trans-dinitrotetrammine, and dichloroaquotriammine salts.
- (vi) *Compounds of the type*, $M_3[CoA_3Y_3'']$, include (1) the Trisulphitotriaminocobaltates of ammonium and cobalt(ie); (2) Trisulphitoaquodiamminocobaltates represented by the cobaltic salt; and the dextro- and lævo-forms of asparaginic acid.

G. T. Morgan and co-workers discussed the metallic lakes of the orthoquinona oximes which form a group of mordant dyes, many of which furnish cobaltic derivatives—*e.g.*, nitroso- β -naphthol, alizarin, dinitrosoresorcinol, and the azosalicyclic acids. The cobalt atom is implicated in a heterocyclic ring both by the principal and supplementary valencies.

V.—**The diammine family**, or compounds of the univalent acidic group: $[CoA_2X_4']$.

- (i) *Tetranitrodiamminocobaltates*, $M[Co(NH_3)_2(NO_2)_4]$, which include the salts: (1) Sodium; (2) Ammonium; (3) Tetramethylammonium; (4) Potassium; (5) Rubidium; (6) Cæsium; (7) Copper; (8) Silver;

- (9) Zinc ; (10) Mercury ; (11) Thallium ; (12) Lead ; (13) Dichlorotetraquochromate ; (14) Dibromotetraquochromate ; (15) Hexacarbamidochromate ; (16) Hexamminocobaltate ; (17) Hydroxypentamminocobaltate ; (18) Chloropentamminocobaltate ; (19) Bromoaquobisethylenediaminocobaltate ; (20) Nitropentamminocobaltic ; (21) Nitroaquopentamminocobaltate ; (22) Nitratopentamminocobaltate ; (23) Dichloroquaterpyridinecobaltate ; (24) Dichloro-aquotriamminocobaltate ; (25) Dinitrotetramminocobaltic—*cis*- and *trans*- ; (26) Carbonatotetramminocobaltate ; (27) Oxalatotetramminocobaltate ; (28) Salicylatotetramminocobaltate ; and (29) Nickel.
- (ii) *Tetranitrobis-p-toluidinecobaltates*, $M[Co(C_7H_7.NH_2)_2(NO_2)_4]$, represented by the *p*-toluidine salt.
- (iii) *Dichlorodinitrodiamminocobaltates*, $M[Co(NH_3)_2(NO_2)_2Cl_2]$, represented by the salt with chloronitrotetrammine.
- (iv) *Dinitrobisdimethylglyoximinocobaltates*, $M[Co\{CH_3C(NO)C(NO)CH_3\}_2(NO_2)_2]$, represented by the acid $H[Co\{CH_3C(NO)C(NO)CH_3\}_2(NO_2)_2].H_2O$, and the (1) Sodium ; (2) Ammonium ; (3) Ethylammonium ; and (4) Bisisobutylammonium salts.
- (v) *Disulphitodiamminocobaltates*, $M[Co(NH_3)_2(SO_3)_2]$, represented by (1) Sodium ; (2) Ammonium ; and (3) Strychnine salts.
- (vi) *Dioxalatodiamminocobaltates*, $M[Co(NH_3)_2(C_2O_4)_2]$, represented by the acid, $H[Co(NH_3)_2(C_2O_4)_2]$, and (1) Ammonium ; (2) Potassium ; (3) Barium ; (4) Cobaltous ; (5) Acid cobaltous ; (6) *trans*-Dinitrotetramminecobaltate ; (7) *trans*-Dichlorotetramminocobaltate ; (8) Oxalatotetramminocobaltate ; and (9) Strychnine salts.
- (vii) *Dioxalatoethylenediaminecobaltate*, $M[Co en(C_2O_4)_2]$, represented by the oxalatobisethylenediaminechromate.
- (viii) *Dinitrooxalatodiamminecobaltates*, $M[Co(NH_3)_2(C_2O_4)(NO_2)_2]$, represented by the acid, $H[Co(NH_3)_2(C_2O_4)(NO_2)_2]$, and the *cis*- and *trans*-salts of (1) Sodium ; (2) Ammonium ; (3) Ethylenediammonium ; (4) Phenylethylammonium ; (5) Copper ; (6) Silver ; (7) Barium ; (8) Magnesium ; (9) Ammonium magnesium ; (10) Zinc ; (11) Cadmium ; (12) Thallium ; (13) Cobaltous ; (14) Ammonium cobaltous ; (15) Potassium cobaltous ; (16) Silver cobaltous ; (17) Hexamminocobaltic ; (18) Aquopentamminocobaltic ; (19) Diaquotetramminocobaltic ; (20) *cis*-Dinitrotetramminocobaltic ; (21) Oxalatotetramminocobaltic ; (22) *iso*-Thiocyanatonitrotetramminocobaltic ; (23) Nickel ; and (24) Strychnine.
- (ix) *Dinitromalonatodiamminocobaltates*, $M[Co(NH_3)_2(C_3H_2O_4)(NO_2)_2]$, represented by the barium salt.
- (x) *Oxalatobisdinitrobisdiamminocobaltate*, $[Co(NH_3)_2(NO_2)_2]_2(C_2O_4)$.

VI.—**The monammine family**, or compounds of the bivalent, acidic group : $[CoA_5X]''$.

This is represented by sodium pentametanitratomonamminocobaltate, $Na_2[Co(NH_3)(NO_2)_2]$.

VII.—**The hexa-acid family**, or compounds of the tervalent acidic group : $[CoX_6]'''$, represented by hexanitritocobaltic acid, $H_3[Co(NO_2)_6]$, and its salts ; hexacyanocobaltic acid, $H_3[CoCy_6]$; pentacyanothiosulphatocobaltic acid, $H_4[CoCy_5(S_2O_3)]$; potassium trisoxalatocobaltate, $K_3[Co(C_2O_4)_3]$; thio-sulphatopentacyanocobaltic acid, $H_4[CoCy_5(S_2O_3)]$, etc.

B.—Compounds with more than one atom of Cobalt in the nucleus.

I.—**Dicobaltic salts**—with two cobalt atoms in the nucleus. Cobaltic melanochloride, and cobaltic fusco-salts have been previously discussed.

(i) *Peroxo-decammines* with two tervalent cobalt atoms, $[(NH_3)_5Co$

- O₂—Co(NH₃)₅]X₄, include (1) Hydroxide; (2) Chloride; (3) Iodide; (4) Sulphate; (5) Hydrosulphate; (6) Chlorosulphate; (7) Selenate; (8) Hydroselenate; (9) Nitrate; (10) Hydronitrate; (11) Hydrochloronitrate; (12) Sulphatonitrate; (13) Cyanate; (14) Thiocyanate; and (15) Nitratothiocyanate.
- (ii) *Peroxo-decammines* with one trivalent and one quadrivalent cobalt atom, [(NH₃)₅Co—O₂—Co(NH₃)₅]X₅, include (1) Chloride, and its double salt with platinum chloride; (2) Sulphate; (3) Hydrosulphate; (4) Chlorosulphate; (5) Selenate; (6) Nitrate; (7) Chloronitrate; (8) Sulphatonitrate; and (9) Dichromate.
- (iii) *Trichlorohydroxy-peroxo-hexammines*, [Cl₂(NH₃)₃Co—O₂—Co(NH₃)₃(OH)Cl]X, represented by the (1) Chloride, and (2) Nitrate.
- (iv) *Sulphato-μ-imino-octammines*, [(NH₃)₄Co=(NH)(SO₄)=Co(NH₃)₄]X₂, represented by the (1) Chloride, and (2) Nitrate.
- (v) *μ-Amino-decammines*, [(NH₃)₅Co—NH₂⋯Co(NH₃)₅]X₅, include (1) Chloride; (2) Bromide; (3) Sulphate; (4) Dithionate; (5) Selenate; and (6) Nitrate.
- (vi) *Nitratoquo-μ-amino-octammines*, [(H₂O)(NH₃)₄⋯NH₂—Co(NH₃)₄(NO₃)]X₄, represented by the nitrate.
- (vii) *Chloroquo-μ-amino-octammines*, [(H₂O)(NH₃)₄Co—NH₂⋯Co(NH₃)₄Cl]X₄, include (1) Chloride; (2) Sulphate; (3) Dithionate; and (4) Selenate.
- (viii) *Chloronitrato-μ-amino-octammines*, [Cl(NH₃)₄Co—NH₂⋯Co(NH₃)₄(NO₃)]X₃, represented by the nitrate.
- (ix) *Bromoquo-μ-amino-octammines*, [(H₂O)(NH₃)₄Co—NH₂⋯Co(NH₃)₄Br]X₄, represented by (1) Bromide; and (2) Sulphate.
- (x) *Thiocyanatochloro-μ-amino-octammines*, [(SCy)(NH₃)₄Co—NH₂⋯Co(NH₃)₄Cl]X₃, represented by the thiocyanate.
- (xi) *Sulphato-μ-amino-octammines*, [(NH₃)₄Co=(NH₂)(SO₄)⋯Co(NH₃)₄]X₃, include (1) Chloride; (2) Bromide; (3) Iodide; (4) Hydrosulphate; (5) Hydroselenate; (6) Nitrate; and (7) Chloronitrate.
- (xii) *Sulphato-μ-amino-quaterethylenediamines*, [en₂Co=(NH₂)(SO₄)⋯Co en₂]X₃, include some optically-active forms: (1) Bromide; (2) Nitrate; (3) Thiocyanate; and (4) Bromocamphorsulphonate.
- (xiii) *Selenato-μ-amino-octammines*, [(NH₃)₄Co=(NH₂)(SeO₄)⋯Co(NH₃)₄]X₃, include (1) Hydrosulphate; (2) Hydroselenate; and (3) Nitrate.
- (xiv) *Tetrachloro-μ-amino-hexammine*, [Cl₂(NH₃)₃Co—NH₂⋯Co(NH₃)₃Cl₂]X, represented by the chloride.
- (xv) *Tetrabromo-μ-amino-hexammines*, [Br₂(NH₃)₃Co—NH₂⋯Co(NH₃)₃Br₂]X, represented by (1) Bromide; and (2) Nitrate.
- (xvi) *Trichloroquo-μ-amino-hexammines*, [Cl₂(NH₃)₃Co—NH₂⋯Co(NH₃)₃(H₂O)Cl]X₂, represented by the chloride.
- (xvii) *Trichloronitrato-μ-amino-hexammines*, [Cl₂(NH₃)₃Co—NH₂⋯Co(NH₃)₃(NO₃)Cl]X, represented by the nitrate.
- (xviii) *Diol-octammines*, [(NH₃)₄Co⋯(OH)₂⋯Co(NH₃)₄]X₄, include (1) Chloride, and the double salts with gold, and platinum chlorides; (2) Chlorate; (3) Bromide; (4) Bromate; (5) Iodide; (6) Iodate; (7) Sulphate; (8) Dithionate; (9) Selenate; (10) Nitrate; (11) Fluosilicate; (12) Phosphate; (13) Chromate; (14) Oxalate; and (15) Thiocyanate.
- (xix) *Diol-quaterethylenediamines*, [en₂Co⋯(OH)₂⋯Co en₂]X₄, include (1) Chloride; (2) Bromide; (3) Iodide; (4) Dithionate; (5) Nitrate; (6) Chromate; (7) Dithionate; (8) Oxalate; and (9) Thiocyanate.
- (xx) *Dinitrato-diol-hexammines*, [(NO₃)(NH₃)₃Co⋯(OH)₂⋯Co(NH₃)₃(NO₃)]X₂, represented by the nitrate.
- (xxi) *Diaquo-diol-hexammines*, [(H₂O)(NH₃)₃Co⋯(OH)₂⋯Co(NH₃)₃(H₂O)]X₄, represented by the sulphate.

- (xxii) *Nitratoquo-diol-hexammines*, $[(\text{H}_2\text{O})(\text{NH}_3)_3\text{Co}\cdots(\text{OH})_2\cdots\text{Co}(\text{NH}_3)_3\cdots(\text{NO}_3)]\text{X}_3$, represented by the dithionate.
- (xxiii) μ -*Diamino-octammines*, $[(\text{NH}_3)_4\text{Co}\cdots(\text{NH}_2)_2\cdots\text{Co}(\text{NH}_3)_4]\text{X}_4$, represented by (1) Bromide; and (2) Dithionate.
- (xxiv) *Hydroxyquo-peroxo-ol-hexammines*, $[(\text{OH})(\text{NH}_3)_3\text{Co}=(\text{OH})(\text{O}_2)\cdots\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})]\text{X}_3$, include (1) Chloride; (2) Bromide; (3) Sulphate, and the double salt with ammonium sulphate; and (4) Nitrate.
- (xxv) μ -*Imino-peroxo-quaterethylenediamines*, $[\text{en}_2\text{Co}=(\text{O}_2)(\text{NH})=\text{Co en}_2]\text{X}_3$, include some optically-active forms: (1) Chloride; (2) Iodide; and (3) Nitrate.
- (xxvi) μ -*Ammonium-peroxo-quaterethylenediamines*, $[\text{en}_2\text{Co}=(\text{O}_2)(\text{NH}_4.\text{HX})=\text{Co en}_2]\text{X}$, include some optically-active forms: (1) Bromide; (2) Dithionate; and (3) Nitrate.
- (xxvii) μ -*Amino-peroxo-octammines*, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{O}_2)\cdots\text{Co}(\text{NH}_3)_4]\text{X}_4$, include (1) Chloride; (2) Bromide; (3) Sulphate; (4) Dithionate; (5) Selenate; (6) Nitrate.
- (xxviii) μ -*Amino-peroxo-quaterethylenediamines*, $[\text{en}_2\text{Co}=(\text{NH}_2)(\text{O}_2)\cdots\text{Co en}_2]\text{X}_4$, include some optically-active forms: (1) Chloride, and a double salt with platinum chloride; (2) Bromide; (3) Dithionate; (4) Nitrate; and (5) Bromocamphorsulphonate.
- (xxix) *Dichloro- μ -amino-peroxo-hexammines*, in isomeric forms, symmetrical, $[\text{Cl}(\text{NH}_3)_3\text{Co}=(\text{NH}_2)(\text{O}_2)\cdots\text{Co}(\text{NH}_3)_3\text{Cl}]\text{X}_2$, and asymmetrical, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{O}_2)\cdots\text{Co}(\text{NH}_3)_2\text{Cl}_2]\text{X}_2$, and represented by (1) Chloride; and (2) Nitrate.
- (xxx) *Dibromo- μ -amino-peroxo-hexammines*, in isomeric forms, symmetrical, $[\text{Br}(\text{NH}_3)_3\text{Co}=(\text{NH}_2)(\text{O}_2)\cdots\text{Co}(\text{NH}_3)_3\text{Br}]\text{X}_2$, and asymmetrical, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{O}_2)\cdots\text{Co}(\text{NH}_3)_2\text{Br}_2]\text{X}_2$, and represented by the bromide.
- (xxxi) μ -*Amino-ol-octammines*, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{OH})\cdots\text{Co}(\text{NH}_3)_4]\text{X}_4$, include (1) Chloride; (2) Bromide; (3) Sulphate; (4) Dithionate; (5) Selenate; (6) Nitrate; and (7) Thiocyanate.
- (xxxii) μ -*Amino-ol-quaterethylenediamines*, $[\text{en}_2\text{Co}\cdots(\text{NH}_2)(\text{OH})=\text{Co en}_2]\text{X}_4$, include some optically-active forms: (1) Bromide; and (2) Iodide.
- (xxxiii) *Diaquo- μ -amino-ol-hexammines*, $[(\text{H}_2\text{O})(\text{NH}_3)_3\text{Co}\cdots(\text{NH}_2)(\text{OH})\cdots\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})]\text{X}_4$, represented by the nitrate.
- (xxxiv) *Nitratoquo- μ -amino-ol-hexammines*, $[(\text{H}_2\text{O})(\text{NH}_3)_3\text{Co}\cdots(\text{NH}_2)(\text{OH})\cdots\text{Co}(\text{NH}_3)_3(\text{NO}_3)]\text{X}_3$, include (1) Chloride; (2) Bromide; and (3) Nitrate.
- (xxxv) *Dichloro- μ -nitro-ol-hexammines*, $[\text{Cl}(\text{NH}_3)_3\text{Co}\cdots(\text{NO}_2)(\text{OH})\cdots\text{Co}(\text{NH}_3)_3\cdots\text{Cl}]\text{X}_2$, include (1) Chloride; (2) Sulphate; (3) Dithionate; and (4) Nitrate.
- (xxxvi) *Dibromo- μ -nitro-ol-hexammines*, $[\text{Br}(\text{NH}_3)_3\text{Co}\cdots(\text{NO}_2)(\text{OH})\cdots\text{Co}(\text{NH}_3)_3\cdots\text{Br}]\text{X}_2$, include (1) Bromide; (2) Dithionate; and (3) Nitrate.
- (xxxvii) μ -*Amino-nitro-octammines*, $[(\text{NH}_3)_4\text{Co}\cdots(\text{NH}_2)(\text{NO}_2)\cdots\text{Co}(\text{NH}_3)_4]\text{X}_4$, include (1) Chloride; (2) Bromide; (3) Iodide; (4) Sulphate; (5) Selenate; and (6) Nitrate.
- (xxxviii) μ -*Amino-nitro-quaterethylenediamines*, $[\text{en}_2\text{Co}\cdots(\text{NH}_2)(\text{NO}_2)\cdots\text{Co en}_2]\text{X}_4$, include some optically-active forms: (1) Bromide; (2) Iodide; (3) Nitrate; (4) Thiocyanate; and (5) Bromocamphorsulphonate.
- (xxxix) *Dichloro- μ -amino-nitrohexammines*, $[\text{Cl}(\text{NH}_3)_3\text{Co}\cdots(\text{NO}_2)(\text{NH}_2)\cdots\text{Co}(\text{NH}_3)_3\text{Cl}]\text{X}_2$, include (1) Chloride; and (2) Nitrate.
- (xl) *Acetatoquo- μ -acetato-ol-hexammines*, $[(\text{H}_2\text{O})(\text{NH}_3)_3\text{Co}\cdots\{\text{OC}(\text{CH}_3)\text{O}\}\text{OH}\cdots\text{Co}(\text{NH}_3)_3(\text{C}_2\text{H}_3\text{O}_2)]\text{X}_3$, represented by the bromide.
- (xli) *Diaquo- μ -acetato-amino-hexammines*, $[(\text{H}_2\text{O})(\text{NH}_3)_3\text{Co}\cdots(\text{NH}_2)\{\text{OC}(\text{CH}_3)\text{O}\}\cdots\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})]\text{X}_4$, include (1) Bromide; and (2) Nitrate.
- (xlii) *Triol-hexammines*, $[(\text{NH}_3)_3\text{Co}\cdots(\text{OH})_3\cdots\text{Co}(\text{NH}_3)_3]\text{X}_3$, include (1)

- Chloride; (2) Bromide; (3) Sulphate; (4) Thiosulphate; (5) Dithionate; (6) Selenate; (7) Nitrate; and (8) Thiocyanate.
- (xliii) *Peroxo-diol-seriespropylamine*, $[(C_7H_7.NH_2)_3 \cdots (OH)_2(O_2) \cdots Co(C_7H_7.NH_2)_3]X_3$, represented by the chloride.
- (xliv) *Peroxo-diol-seriesallylamines*, $[(C_3H_5.NH_2)_3 \cdots (OH)_2(O_2) \cdots Co(C_3H_5.NH_2)_3]X_3$, include (1) Chloride; and (2) Nitrate.
- (xlv) *Peroxo-diol-seriesbenzylamine*, $[C_6H_5.CH_2.NH_2)_3 \cdots (OH)_2(O_2) \cdots Co(C_6H_5.CH_2.NH_2)_3]X_3$, represented by the chloride.
- (xlvii) μ -*Amino-diol-hexammines*, $[(NH_3)_3Co \cdots (NH_2)(OH)_2 \cdots Co(NH_3)_3]X_3$, include (1) Chloride; (2) Bromide; (3) Iodide; and (4) Nitrate.
- (xlviii) μ -*Nitro-diol-hexammines*, $[(NH_3)_3Co \cdots (NO_2)(OH)_2 \cdots Co(NH_3)_3]X$, include (1) Chloride; (2) Bromide; (3) Sulphate; (4) Selenate; and (5) Nitrate.
- (xlviii) μ -*Dinitro-ol-hexammines*, $[(NH_3)_3Co \cdots (NO_2)_2(OH) \cdots Co(NH_3)_3]X_3$, include (1) Chloride; and (2) Nitrate.
- (xlix) μ -*Acetato-diol-hexammines*, $[(NH_3)_3Co \cdots (OH)_2\{OC(CH_3)O\} \cdots Co(NH_3)_3]X_3$, include (1) Chloride; (2) Bromide; (3) Iodide; (4) Nitrate; (5) Bromodithionate; and (6) Thiocyanate.
- (i) μ -*Amino-ol-peroxo-hexammines*, $[(NH_3)_3Co \cdots (NH_2)(OH)(O_2) \cdots Co(NH_3)_3]X_3$, include (1) Chloride; (2) Bromide; and (3) Nitrate.
- (ii) μ -*Acetato-amino-ol-hexammines*, $[(NH_3)_3Co \cdots (NH_2)(OH)\{OC(CH_3)O\} \cdots Co(NH_3)_3]X_3$, include (1) Chloride, and its double salt with platinum; (2) Bromide; (3) Iodide; (4) Nitrate; and (5) Thiocyanate.

II.—Tricobaltic salts, with three cobalt atoms in the nucleus.

- (i) *Diaquo-tetrol-quaterethylenediamines*, $[en_2Co=(OH)_2Co(H_2O)_2 \cdots (OH)_2=Co en_2]X_4$, represented by (1) Chloride, and its double salt with platinum chloride; (2) Iodide; (3) Sulphate; and (4) Dithionate.
- (ii) *Diaquo-pentol-hexammines*, $[(H_2O)(NH_3)_3Co=(OH)_2(H_2O) \cdots Co \cdots (OH)_3 \equiv Co(NH_3)_3]X_4$, represented by the chloride.
- (iii) *Hexol-hexammines*, $[(NH_3)_3Co \geq (OH)_3 \cdots Co \cdots (OH)_3 \equiv Co(NH_3)_3]X_3$, include (1) Chloride; (2) Bromide; (3) Sulphate; and (4) Dithionate.
- (iv) *Diphosphatobisethylenediamines*, represented by the phosphate.
- (v) *Diphosphatobispropylenediamines*, represented by the phosphate.

III.—Tetracobaltic salts, with four cobalt atoms in the nucleus.

- (i) *Hexol-dodecammines*, $[Co\{(OH)_2=Co(NH_3)_4\}_3]X_6$, include some optically-active forms: (1) Chloride, and a double salt with platinum chloride; (2) Bromide; (3) Sulphate; (4) Thiosulphate; (5) Dithionate; (6) Selenate; (7) Nitrate; (8) Fluosilicate; (9) Molybdate; (10) Bromocamphorsulphonate; (11) Picrate; and (12) Dipicrylamide.
- (ii) *Hexol-seriesethylenediamines*, $[Co\{(OH)_2=Co en_2\}_3]X_6$, include (1) Chloride; (2) Bromide; (3) Iodide; (4) Nitrate; and (5) Thiocyanate.

There is a number of salts whose constitution is unknown; there are several possible explanations. In some cases the results have not been checked up under the guidance of the theory. The theory would have made the investigators extra critical in the case of indecisive results. There are the oxy-salts of G. Künzel,³ namely, $Co_4(NH_3)_{20}O(NO_3)_{10}$, and $Co_4(NH_3)_8O(S_2O_6)_2$; E. Frémy's $Co_3(NH_3)_2O_3Cl_2.5H_2O$; S. P. L. Sørensen's $Co_2O(NH_3)_4(C_2O_4)_2.2H_2O$, and $Co_4O_3(NH_3)_6(C_2O_4)_3.10H_2O$; and A. Werner's *ozo-trimido-salts*, $[Co_4(O_2)_2(NH_3)_3(NH_3)_{10}](NO_3)_5$, and with Cl or Br in place of the nitrate-radicle; A. Werner and R. Feenstra's *imido-compounds*, $Co_2(NH_3)_8py_2(NH)Cl_4$, and the corresponding iodide, as well as A. Werner and F. Steinitzer's $Co_2(NH_3)_6(NH)Br_4$, as well as the corresponding iodide. E. Frémy, C. D. Braun, and G. Vortmann reported the *cobaltic fusco-salts*, $Co_2(NH_3)_6(OH)_4(NO_3)_2$; $Co_2(NH_3)_8(OH)_2(NO_3)_4.2H_2O$; $Co_2(NH_3)_8(OH)_2Cl_4.2H_2O$; $Co_2(NH_3)_2(OH)_2(SO_4)_2.3H_2O$; $Co_2(NH_3)_6(SO_4)_3.6H_2O$; $Co_2(NH_3)_6(OH)_2(CO_3)_2.3H_2O$; and the $Co_2(NH_3)_2(SO_3)_3.5H_2O$, and $Co_2(NH_3)_5(SO_3)_3.7H_2O$ of K. A. Hofmann and S. Reinsch. There are K. A. Hofmann's *sulpho-salts* and *thiocarbonates*: $Co_2(CS_3)_2S(NH_3)_4$.

$2\text{H}_2\text{O}$; $\text{Co}_2(\text{CS}_3)_2\text{S}_2(\text{NH}_3)_5$; $\text{Co}_2(\text{CS}_3)_2\text{S}_2(\text{NH}_3)_5\cdot\text{H}_2\text{O}$; and $\text{Co}_2(\text{CS}_3)_3\text{S}(\text{NH}_3)_2(\text{CH}_3\cdot\text{COOH})$. $4\text{H}_2\text{O}$. The following mixed salts were reported by G. Vortmann and O. Blasberg, or by G. Vortmann and G. Magdeburg: $\text{Co}(\text{NH}_3)_4\text{Cl}_2\cdot\text{I}\cdot\text{H}_2\text{O}$; $\text{Co}(\text{NH}_3)_4(\text{SO}_3)\text{Cl}\cdot 2\text{H}_2\text{O}$; $\text{Co}(\text{NH}_3)_4(\text{SO}_4)\text{Br}$; $\text{Co}(\text{NH}_3)_4(\text{SO}_4)\text{I}$; and $\text{Co}(\text{NH}_3)_4(\text{NO}_3)\text{I}\cdot\text{H}_2\text{O}$. J. Beato and M. de los D. Brugger obtained complexes with the cobaltic chloride and cyclicamines—dimethylglyoxime associated with aniline, or *o*- or *p*-toluidine. Similar complexes were not formed with benzaldioxime or formaldioxime in place of diacetyldioxime.

§ 18. Cobaltous Bromide

According to J. B. Berthelot,¹ cobalt at a dull red-heat unites with bromine to form cobaltous bromide, CoBr_2 , which fuses and is partially decomposed at a

higher temp. F. Ducelliez and A. Raynaud said that the action of bromine is perceptible above the b.p. In order to purify the salt, T. W. Richards and G. P. Baxter recommended subliming the product in a mixture of hydrogen bromide, and C. F. Rammelsberg, and W. N. Hartley said that the hydrates pass into the anhydrous salt when heated to 130° . J. Nicklés observed that cobalt is only slightly attacked by a soln. of bromine in ether; and F. Ducelliez and A. Raynaud observed that the salt $\text{CoBr}_2 \cdot 2(\text{C}_2\text{H}_5)_2\text{O}$ is formed, and when heated, the ether is given off, and anhydrous cobaltous bromide remains. F. Bourion heated cobalt oxide in a current of hydrogen bromide mixed with a little sulphur monochloride as in the case of the corresponding nickel salt. Black cobalt oxide was found by M. Barre to be attacked at ordinary temp. by sulphur monobromide; the reaction is rapid at 350° ; and at 700° , the product sublimes as a product of a high degree of purity—at 500° , 5 grms. of oxide were converted into the bromide in 1 hour. G. Crut found that dry hydrogen bromide converts anhydrous cobalt chloride into bromide at 500° ; and A. Grün and E. Boedecker obtained the anhydrous bromide by heating the complex with pinacone over 100° . According to W. N. Hartley, I. Guareschi, and G. L. Clark and H. K. Buckner, the formation of the anhydrous bromide from the hydrate proceeds very slowly in vacuo over conc. sulphuric acid at ordinary temp. W. Biltz and B. Fetkenheuer recommended drying the hexahydrate in a desiccator over caustic alkali for some hours, then warming it to 40° , and finally dehydrating the salt at 140° to 160° . The rise of temp. must be slow to avoid melting the salt. W. N. Hartley, and A. Hantzsch and F. Schlegel recommended heating the hydrate to 130° ; and I. Guareschi, to 100° . A. Ferrari and F. Giorgi heated the hydrate in a current of hydrogen bromide to avoid the formation of a basic salt.

J. B. Berthémot obtained a soln. of cobalt bromide by the action of a boiling mixture of water and bromine on cobalt; C. F. Rammelsberg added that the action is accelerated by contact with platinum. W. N. Hartley treated for a week at ordinary temp. a mixture of bromine with a little water, and evaporated the soln. in vacuo over sulphuric acid. The aq. soln. was also obtained by J. B. Berthémot by dissolving cobaltous hydroxide in hydrobromic acid; and by G. L. Clark and H. K. Buckner, by dissolving the carbonate in hydrobromic acid of sp. gr. 1.49. The evaporation of the aq. soln. furnishes purple-red or rose-red, prismatic crystals of the *hexahydrate*, $\text{CoBr}_2 \cdot 6\text{H}_2\text{O}$, which, according to W. N. Hartley, at 100° , forms the reddish-violet *dihydrate*, $\text{CoBr}_2 \cdot 2\text{H}_2\text{O}$. I. Guareschi said that several intermediate hydrates are formed by heating the hexahydrate in dry air. A. Hantzsch and F. Schlegel, and I. Guareschi obtained the dihydrate by keeping the hexahydrate in vacuo over sulphuric acid or phosphorus pentoxide at ordinary temp. G. L. Clark and H. K. Buckner said that all the water is abstracted if the hexahydrate be kept in vacuo over sulphuric acid. I. Guareschi observed that the dihydrate passes into the blue *monohydrate*, $\text{CoCl}_2 \cdot \text{H}_2\text{O}$, at 80° ; and A. Hantzsch and F. Schlegel, at 90° . I. Guareschi added that rose-coloured *hemihydrate*, $\text{CoBr}_2 \cdot 5\frac{1}{2}\text{H}_2\text{O}$; pink *pentahydrate*, $\text{CoBr}_2 \cdot 5\text{H}_2\text{O}$; reddish-violet *tetrahydrate*, $\text{CoBr}_2 \cdot 4\text{H}_2\text{O}$; and the *hemihydrate*, $\text{CoBr}_2 \cdot \frac{1}{2}\text{H}_2\text{O}$, are formed during the dehydration of the hexahydrate, but it is very doubtful if these alleged hydrates are chemical individuals. A. Hantzsch and H. Carlsohn discussed the nature of this salt.

Physical properties.—The anhydrous bromide, left on dehydrating the hydrate, is a bright green powder; and the sublimed bromide appears in green, tabular crystals. The hexahydrate furnishes rose-red crystals; the dihydrate forms a purple-blue mass; and the monohydrate, a blue, hygroscopic mass. A. Ferrari and F. Giorgi found that the X-radiograms indicated that the space-lattice is of the cadmium iodide type. The space-lattice of the hexagonal crystals has $a=3.685 \text{ \AA.}$, $c=6.120 \text{ \AA.}$, and $a:c=1:1.66$. The corresponding calculated sp. gr. is 5.072. G. L. Clark and H. K. Buckner observed 4.91 for the sp. gr. of the anhydrous salt. T. W. Richards and G. P. Baxter gave 4.909 at $25^{\circ}/4^{\circ}$; and W. Biltz and E. Birk, 4.849 at $25^{\circ}/4^{\circ}$; G. L. Clark and H. K. Buckner gave 2.46 for the sp. gr. of the hexahydrate at $25^{\circ}/4^{\circ}$. A. Heydweiller gave for the sp. gr. of aq. soln., at 18° :

	4N-	3N-	2N-	N-	0.5N-	0.2N-	0.1N-
Sp. gr. .	1.3278	1.2474	1.1661	1.0837	1.04213	1.0170	0.00849
λ .	33.22	41.3	51.3	63.8	72.8	81.7	87.7

W. Biltz and E. Birk gave 45.12 for the mol. vol. of the anhydrous salt. W. Biltz, I. I. Saslawsky, F. Ephraim, and F. Ephraim and O. Schütz discussed the mol. vol., and the contraction which attends the formation of the salt from its elements; and G. L. Clark and H. K. Buckner noted that there is a 18.58 per cent. contraction in forming the hexahydrate: $\text{CoBr}_2 + 6\text{H}_2\text{O} = \text{CoBr}_2 \cdot 6\text{H}_2\text{O}$. U. Panichi discussed the relation between the at. vol. of the contained elements and the sp. gr. of cobalt bromide. D. Isaachsen observed that the lowering of the f.p. of water, and the raising of the b.p. of water suggested that in aq. soln. cobalt bromide is present in the form of CoBr_2 -mols.; A. Werner came to a similar conclusion with respect to the b.p. of pyridine soln.; and E. Beckmann, with respect to the b.p. of quinoline soln.

G. Devoto and A. Guzzi gave 678° for the m.p. of the anhydrous bromide in nitrogen; and A. Ferrari and F. Giorgi, 687° for the m.p. in hydrogen bromide. According to I. Guareschi, the hexahydrate melts at 49° to a blue liquid; and W. N. Hartley gave 47° to 48° for the m.p., and added that at 100°, the deep blue liquid gives off water to form the dihydrate, and at 130°, the anhydrous salt. D. Isaachsen measured the lowering of the f.p., and the raising of the b.p. of aq. soln., and the results agree with the formation of three ions: $\text{CoBr}_2 \rightleftharpoons \text{Co}^{++} + 2\text{Br}^-$. K. Jellinek and R. Ulroth gave for the dissociation press. $p_{\text{Br}_2} = 4.07 \times 10^{-10}$ at 500°; 8.71×10^{-9} at 575°; and 1.41×10^{-7} at 650°. W. Biltz and E. Birk, and H. Fesefeldt noted that the salt sublimates when heated in vacuo. G. Crut gave for the heat of formation of the anhydrous bromide from gaseous bromine, $(\text{Co}, \text{Br}_2) = 63.8$ Cals.; J. Thomsen gave $(\text{Co}, \text{Br}_2, \text{Aq.}) = 72.94$ Cals.; M. Berthelot, $(\text{Co}, \text{Br}_2, \text{Aq.}) = 13.4$ Cals. with liquid bromine, and 80.8 Cals. with gaseous bromine. G. Crut gave 18.4 Cals. for the heat of soln. of the anhydrous salt in water, and -1.28 Cals. for the hexahydrate. G. Devoto and A. Guzzi calculated 28,940 Cals. for the free energy of formation of the molten salt. The subject was discussed by F. Ephraim.

R. W. Roberts measured the indices of refraction of soln. with 0.110 grm. of CoBr_2 per c.c. of soln. (sp. gr. 1.100), for light of wave-length λ , and found 1.3520 for $\lambda = 589.3m\mu$, and 1.3704 for $\lambda = 353.5m\mu$. G. Limann made observations on the subject. A. Heydweiller measured the dispersion of the soln.; and G. Limann gave 26.03 for the mol. refraction for the D-line with the μ^2 -formula. H. Fesefeldt measured the absorption spectrum of thin films of anhydrous cobalt bromide, and observed bands between 250 and 300 $m\mu$. R. W. Roberts measured the magnetic rotation of the plane of polarized light and found it to be positive like that of the chloride. The colour, and absorption spectrum were studied by W. R. Brode, W. R. Brode and R. A. Morton, F. L. Cooper, G. Denigès, R. A. Houstoun and co-workers, R. J. Macwalter and S. Barratt, and H. C. Jones and co-workers.

A. Heydweiller's values for the eq. electrical conductivity of aq. soln. of an eq. of the salt, in v litres of water, at 18°, are indicated above. W. Althammer found for the mol. conductivity of soln. with a mol. of the salt, in v litres, at 25°:

v .	20	80	320	1280	5120
μ .	99.5	110.0	118.6	124.0	127.4

L. G. Winston and H. C. Jones' values are:

v	4	32	128	1024	2048	2096
λ 0° .	87.82	105.56	115.88	120.80	124.00	125.45
25° .	155.60	193.09	214.02	231.56	234.28	236.78
35° .	196.30	233.04	259.91	281.16	283.65	289.34
α 0° .	70.0	84.1	92.3	96.3	98.8	100.0
25° .	65.7	81.5	90.4	97.8	98.9	100.0
35° .	67.8	80.5	89.8	97.2	97.7	100.0

The values for the percentage ionizations, α , were calculated from the conductivity data. Observations were also made by H. C. Jones and A. P. West, and H. C. Jones and W. W. Strong. A. Heydweiller gave for the limiting value at infinite dilution $\lambda=111$ at 18° ; G. Bredig, 129.7 at 25° ; and W. Althammer, 128.9 at 25° . The effect of temp. was discussed by L. G. Winston and H. C. Jones, H. C. Jones and A. P. West, J. Hamacher, and D. Isaachsen. W. Althammer calculated the degree of hydrolysis of soln. with 0.05 and 0.01 mol per litre to be respectively 0.15 and 0.62, at 25° . W. Althammer found the transport number of the anion in soln. with a mol. of the salt in v litres, at 18° : 0.6088 for $v=52.41$, and 0.6045 for $v=197.6$; and for the cation, with soln. containing C mol of the salt per litre, at 25° :

C . . .	0.090	0.459	1.345	3.106	4.731	5.554
n . . .	0.409	0.413	0.340	0.215	0.005	-0.444

n is constant in dil. soln., and the decrease which occurs with increasing concentration is attributed to the formation of complex salts. P. B. Davis and co-workers measured the conductivity of soln. in formamide.

G. Devoto and A. Guzzi found the decomposition potential of fused cobalt bromide to be 0.680 volt at 700° , 0.534 volt at 800° , and 0.398 volt at 900° . W. Althammer gave for the e.m.f. of the cell (pt) H_2 | $CoBr_2$ | $KCl_{sat. soln.}$ | 0.1N-KCl, Hg_2Cl_2 | Hg, 0.576 and 0.578 volt, respectively, for soln. of cobalt bromide with 0.05 and 0.01 mol per litre. G. Tammann and H. O. von Samson-Himmelsjerna studied the potential of cobalt in soln. of the bromide; and H. N. Holmes, the electrostenolysis of soln. of the salt.

W. Klemm and W. Schüth found that the magnetic susceptibilities of cobaltous bromide at $91^\circ K.$, $195^\circ K.$, $293^\circ K.$, and $513^\circ K.$, were, respectively, $\chi \times 10^6=187$, 93.4, 61.0, and 32.0. A. Quartaroli found that conc. aq. soln. of cobalt bromide are paramagnetic, and that with dil. soln., the diamagnetic properties of the water dominate with concentrations below 3.81 grms. of cobalt per litre. O. Liebknecht and A. P. Wills gave 47.3×10^{-6} mass unit for the magnetic susceptibility of a soln. at 18° . C. Falkenberg and R. Oppermann, and R. Oppermann studied the subject.

Chemical properties.—For the reduction of cobalt bromide by **hydrogen**, *vide supra*, cobalt. F. de Carli compared the results with those of other metal halides. G. Crut observed that the reduction of cobalt bromide by hydrogen is a reversible process: $CoBr_2 + H_2 \rightleftharpoons 2HBr + Co$, and the equilibrium constant, $K = p_{HBr}/p_{H_2}$, was found by K. Jellinek and R. Ulroth to be 0.190 at 500° , 0.485 at 575° , and 1.35 at 650° . G. Crut observed the press., p mm., of the gas phase, and the vol. per cent. of HBr, in the gas phase to be:

	445°			576°		
p . . .	656.1	333.5	145.5	706	483.3	243.5
HBr . . .	8.7	13.13	18.16	50.9	58.9	71.7

The chemical constant of the reaction is 11.87, and the heat of the reaction is 39.2 Cals. at 15° . I. Guareschi, and M. Barre said that on exposing anhydrous cobalt bromide to **air**, the dihydrate is formed, and C. F. Rammelsberg, and T. W. Richards and G. P. Baxter, that with a prolonged exposure, the hexahydrate is formed. J. B. Berthemot, and C. F. Rammelsberg also said that the hexahydrate deliquesces in air, forming a red liquid, but in dry air, efflorescence occurs. I. Guareschi, and H. Schulze showed that when heated in air, cobalt bromide gives off bromine, and forms the oxide. T. W. Richards and G. P. Baxter observed that when heated in **oxygen**, cobalt bromide is more readily attacked than is the case with nickel bromide; and similarly with **water** vapour. J. B. Berthemot, and T. W. Richards and G. P. Baxter observed that the salt is readily dissolved by cold water. A. Étard gave for the percentage solubility: 66.7 at 59° , 66.8 at 75° , and 68.1 at 97° . P. Job studied the constitution of **hydrobromic acid** soln. of the bromide, and obtained indications of the ions $CoBr^+$, and $CoBr_3^-$. C. Dufraise and D. Nakae

studied the catalytic effect on the oxidation of soln. of **sodium sulphite**; A. Hantzsch and H. Carlsohn, the reaction with dil. **sulphuric acid**; and P. Walden, the solubility of the salt in **chlorosulphonic acid**.

C. F. Rammelsberg showed that dry cobaltous bromide absorbs dry **ammonia**, becoming first red, and then forming brownish-red **cobaltous hexamminobromide**, $\text{CoBr}_2 \cdot 6\text{NH}_3$. The salt was also prepared by F. Ephraim in this manner. C. F. Rammelsberg added that the complex salt loses ammonia when it is heated; with water it forms green flecks of bromiferous hydroxide, and a brown ammoniacal liquid. W. Biltz and B. Fetkenheuer obtained it by treating a hot, conc., aq. soln. of the bromide with conc. aq. ammonia until the precipitate passes into soln., then adding air-free alcohol until a turbidity appears, and then cooling. The precipitated hexammine can be washed with alcohol. A. Naumann and J. Rill obtained the hexammine, in rose-red crystals, by passing ammonia gas into a soln. of cobaltous bromide in methyl acetate. W. Biltz observed no evidence of the formation of a decammine, analogous to the cobaltous decamminochloride (*q.v.*), which is formed at approximately -78° . W. Biltz and E. Birk gave 10.42 A. for the lattice parameter (*vide supra*, the chloride); and G. B. Naess and O. Hassel, $a=10.39$ A., and 4.50 A. for the distance between the Co and Br atoms. The sp. gr. of the rose-red crystals of the hexammines prepared by the wet process, was found by W. Biltz and E. Birk to be 1.871 at $25^\circ/4^\circ$, and the mol. vol. 171.6; they gave 1.879 for the sp. gr. of the salt prepared by the dry process; and G. L. Clarke and H. K. Buckner gave 1.955. The mol. vol. of the contained ammonia was discussed by W. Biltz. The dissociation temp. for $p=100$ mm. was found by W. Biltz and G. F. Hüttig to be 121° ; and F. Ephraim found the dissociation press., p mm., at different temp. to be:

	104°	121.5°	142°	159.5°	170.5°	175°	176.5°
p	74	110	207	405	590	684	728

The results are plotted in Fig. 113. Observations were also made by W. Peters. W. Biltz and B. Fetkenheuer obtained rather larger values than did F. Ephraim; at 136.8° , they observed $p=200$ mm. in place of F. Ephraim's 177 mm. W. Biltz and B. Fetkenheuer found it melts with decomposition at 258° . The heat of formation from cobaltous bromide and ammonia was found by W. Biltz and co-workers to be 16.19 Cals. per mol. of NH_3 ; and from $\text{CoBr}_2 \cdot 2\text{NH}_3$, 14 Cals. per mol. of NH_3 . G. Beck gave 452 Cals. for the heat of formation. The subject was discussed by G. L. Clark, and W. Hieber and E. Levy. W. R. Brode and R. A. Morton examined the spectra of soln. of cobalt bromide in hydrobromic acid.

FIG. 113.—Dissociation Pressure of the Cobaltous Amminobromides.

A. Naumann and J. B. Kämmerer observed that if ammonia be passed into a half-sat. soln. of cobaltous bromide in benzonitrile, the blue precipitate which is formed turns rose-red, and its composition corresponds with **cobaltous tetramminobromide**, $\text{CoBr}_2 \cdot 4\text{NH}_3$. It is soluble in dil. acids, but only attacked with difficulty by conc. hydrochloric and nitric acids. The thermal dissociation of the hexammine gives no evidence of the formation of the tetrammine, since the reaction can be symbolized, $\text{CoBr}_2 \cdot 6\text{NH}_3 \rightleftharpoons \text{CoBr}_2 \cdot 2\text{NH}_3 + 4\text{NH}_3$. W. Biltz and B. Fetkenheuer observed that the hexammine passes into **cobaltous diamminobromide**, $\text{CoBr}_2 \cdot 2\text{NH}_3$, at 136° . A. Naumann and J. Rill prepared a diammine by heating the hexammine to 120° , and, as in the case of the β -diamminochloride (*q.v.*), the product is called *stable* or α -form, or the *cis*-form, the other bluish-violet variety is the *unstable* or β -form, or the *trans*-form. W. Biltz, and W. Biltz and B. Fetkenheuer observed that there is complete series of solid soln. between the hexammine and the diammine, as in the analogous case of the aminochlorides (*q.v.*). The dissociation press. of the diammine is 0.43 mm. at 152.4° ; 0.695 mm. at 160.5° ; 2.04 mm.

at 181.8° ; and 100 mm. at 279° —*vide* Fig. 113. W. Hieber and E. Levy studied the energy of formation of the diammine; and W. Klemm and W. Schüth, the magnetic susceptibilities. The diammine dissociates to furnish **cobaltous monamminobromide**, $\text{CoBr}_2 \cdot \text{NH}_3$. The heat of formation of the diammine is 20.58 Cals. per mol. of NH_3 . The m.p. is 260° . W. Biltz and B. Fetkenheuer obtained the monammine by heating the diammine to 181.8° , or, according to G. L. Clark and H. K. Buckner, by heating a mixture of the theoretical proportions of cobaltous bromide and its hexammine, in a sealed tube, at 230° . W. Biltz, and W. Biltz and B. Fetkenheuer observed that at 161.4° , 181.8° , 188.6° , and 208.4° the respective dissociation press. are : 0.29, 0.99, 1.22, and 3.46 mm., and at 297° , 100 mm.—*vide* Fig. 113. The product of the dissociation is anhydrous cobaltous bromide. According to W. Biltz and co-workers, the heat of formation of the monammine is 21.1 Cals.

H. Franzen and O. von Mayer prepared **cobaltous dihydrazinodibromide**, $\text{CoBr}_2 \cdot 2\text{N}_2\text{H}_4$, by shaking 5 grms. of cobaltic bromopentamminobromide with 50 c.c. of a 50 per cent. soln. of hydrazine hydrate. When the evolution of ammonia has ceased, the mixture is heated on a water-bath, and on cooling, the salt is deposited as a violet powder. The salt is decomposed by boiling water; and when heated in a current of carbon dioxide, the hydrazine is expelled. W. Hieber and co-workers studied the energy of formation. A. Ferratini reported that **cobaltous hemipentamminodibromide**, $\text{CoBr}_2 \cdot 2\text{N}_2\text{H}_4 \cdot \frac{1}{2}\text{N}_2\text{H}_4$, is formed by aq. soln. of the components, and boiling the product with 94 per cent. alcohol. The dark violet powder melts between 200° and 213° ; it is readily soluble in water; and decomposed by alcohol. P. Walden observed that cobaltous bromide is very sparingly soluble in **arsenic tribromide**; B. A. Isbekoff and W. Plotnikoff found that it forms a homogeneous, bluish-green mass with molten **aluminium bromide**, and that the sp. conductivity of the soln. at 150° is 0.0008 mho.

I. Guareschi noted that cobalt bromide is slightly soluble in dry **chloroform**; and that it is soluble in **methyl alcohol**; and E. Lloyd and co-workers gave for the solubility, S grm. of CoBr_2 per gram of methyl alcohol :

S	20° 0.430	30° 0.586	35° 0.800	40° 1.248	50° 1.419	60° 1.531	70° 1.690	80° 1.906
	$\text{CoBr}_2 \cdot 6\text{CH}_3\text{OH}$			$\text{CoBr}_2 \cdot 3\text{CH}_3\text{OH}$			$\text{CoBr}_2 \cdot 2\text{CH}_3\text{OH}$	

Observations of the complex $\text{CoBr}_2 \cdot 6\text{CH}_3\text{OH}$ were made by A. Hantzsch and F. Schlegel; E. Lloyd and co-workers found the partial press. at 10° , 20° , and 30° to be, respectively, 14.4, 31.0, and 64.1 mm. E. Lloyd and co-workers found the partial press. of the complex $\text{CoBr}_2 \cdot 3\text{CH}_3\text{OH}$ to be 17 mm. at 20° , and of the complex $\text{CoBr}_2 \cdot 2\text{CH}_3\text{OH}$, 10 mm. The latter complex was also studied by A. Hantzsch and F. Schlegel. The colour and absorption spectrum of the soln. were studied by F. L. Cooper, A. Hantzsch, and H. C. Jones and J. A. Anderson; and the mol. conductivity by H. R. Kreider and H. C. Jones. E. Lloyd and co-workers found the solubility, S grm. of CoBr_2 per gram of **ethyl alcohol**, to be :

S	10° 0.706	20° 0.771	30° 0.849	40° 0.959	50° 1.050	60° 1.208	65° —	70° 1.271	80° 1.294
	$\text{CoBr}_2 \cdot 3\text{C}_2\text{H}_5\text{OH}$					$\text{CoBr}_2 \cdot 2\text{C}_2\text{H}_5\text{OH}$			

The partial pressure of $\text{CoBr}_2 \cdot 3\text{C}_2\text{H}_5\text{OH}$ is 1.51, 10.5, and 50.6 mm., respectively, at 10° , 30° , and 50° ; and 2 mm. at 20° for $\text{CoBr}_2 \cdot 2\text{C}_2\text{H}_5\text{OH}$. A. Hantzsch and F. Schlegel obtained $\text{CoBr}_2 \cdot 2\text{C}_2\text{H}_5\text{OH}$ by concentrating the alcoholic soln. over phosphorus pentoxide. The colour and absorption spectrum of the soln. were studied by W. R. Brode, F. L. Cooper, R. A. Houstoun and A. R. Brown, R. A. Houstoun and A. H. Gray, and H. C. Jones and J. A. Anderson; the mol. conductivity, by H. R. Kreider and H. C. Jones; and the transport number, by H. G. Denham. Alcoholic sulphuric acid was found by A. Hantzsch and H. Carlsohn immediately to

decompose the alcoholic soln. of cobalt bromide. A. Hantzsch discussed the colour of the soln. in **amyl alcohol**; and A. Hantzsch and F. Schlegel, the colour of soln. in **benzyl alcohol**, and also the formation of a complex salt. A. Hantzsch discussed the colour of soln. in **ethylene glycol**; and A. Grün and E. Boedecker observed the formation of the complex salts, $\text{CoBr}_2 \cdot 3\text{C}_2\text{H}_4(\text{OH})_2$, and $\text{CoBr}_2 \cdot 2\text{C}_2\text{H}_4(\text{OH})_2$. A. Grün and E. Boedecker also observed a complex salt is formed with **pinacone**, $\text{CoBr}_2 \cdot 3\text{C}_6\text{H}_{12}(\text{OH})_2 \cdot 2\text{H}_2\text{O}$. A. Hantzsch found that **glycerol** forms a rose-red soln. at ordinary temp.; H. C. Jones and W. W. Strong studied the absorption spectrum; and H. C. Jones and J. S. Guy, the mol. conductivity. P. Walden measured the conductivity of soln. in **acetaldehyde**, and in **benzaldehyde**. C. Dufraisie and D. Nakae studied the catalytic action of cobalt bromide on the oxidation of **acraldehyde**, **phenylaldehyde**, **furfuraldehyde**, **styrene**, and **turpentine**. I. Guareschi noted the solubility of the bromide in **methylethylketone**. A. Hantzsch studied the colour of soln. of cobalt bromide in **ether**; and F. Ducelliez and A. Raynaud, the complex $\text{CoBr}_2 \cdot (\text{C}_2\text{H}_5)_2\text{O}$. W. Eidmann, A. Hantzsch and H. Carlssohn, A. Naumann, and I. Guareschi studied the colour of soln. in **acetone**. The solubility, S grm. of CoBr_2 per gram of acetone, was found by W. R. G. Bell and co-workers to be:

	0°	10°	15°	30°	40°
<i>S</i>	0.541	0.543	0.650	0.696	0.924

when the solid phase is $\text{CoBr}_2 \cdot \text{C}_3\text{H}_6\text{O}$, the partial press. at 10°, 20°, and 30° are, respectively, 4.0, 11.7, and 25.2 mm. I. Guareschi studied the complex with **acetophenone**, namely, $\text{CoBr}_2 \cdot \text{CH}_3 \cdot \text{CO} \cdot \text{C}_6\text{H}_5$.

I. Guareschi found that the bromide forms a bluish-violet soln. with **formic acid**, and P. Walden measured the conductivity of soln. in **acetic anhydride**. According to A. Naumann, one gram of cobalt bromide dissolves in 9.74 grms. of **methyl acetate**, at 18°, to form a soln. of sp. gr. 1.013 at 18°/4°; and the salt is sparingly soluble in **ethyl acetate**—A. Hantzsch studied the absorption spectrum of the soln.; and J. Schröder and H. Steiner, the raising of the b.p. A. Naumann and J. Rill said that hydrogen sulphide produces a slight turbidity with the soln., and ammonium sulphide precipitates cobalt sulphide quantitatively. P. Walden measured the conductivity of soln. in **cyanoacetic ether**, in **methyl thiocyanate**, and in **dimethyl malonate**. R. Fosse studied the complex formed with **dinaphthopyryliumbromide**.

P. Walden said that cold soln. of cobalt bromide in **formamide** are red, and that hot soln. are blue; I. Guareschi said that both hot and cold soln. are blue. P. B. Davis and co-workers measured the viscosity, mol. conductivity, and the degree of ionization of soln. at different temp. When the soln. is heated with mercuric chloride, mercury and anhydrous cobalt chloride are formed. A. Naumann observed that warm acetonitrile dissolves cobalt bromide, and A. Hantzsch obtained a complex, $\text{CoBr}_2 \cdot 2\text{CH}_3\text{CN}$, from a soln. of cobalt bromide in warm **acetonitrile**; P. Walden noted the electrical conductivity of the soln. A. Hantzsch obtained a complex with **isopropionitrile**, or **carbylamine**. F. Schlegel studied the complex with diacetonitrile. A. Naumann and J. B. Kämmerer observed that cobalt bromide readily dissolves in **benzonitrile**, forming a deep blue soln. which furnishes $\text{CoBr}_2 \cdot 2\text{C}_6\text{H}_5\text{CN}$, and if air is present, $\text{CoBr}_2 \cdot 2\text{C}_6\text{H}_5\text{CN} \cdot 6\text{H}_2\text{O}$. The colour of the soln. becomes red when silver nitrate, mercuric chloride, or cadmium iodide is added; lithium iodide makes the soln. apple-green; chlorine produces cobalt chloride; hydrogen sulphide yields a small precipitate; and ammonium sulphide precipitates cobalt sulphide quantitatively. Double salts are formed with cadmium iodide, and mercuric chloride.

F. Ephraim and R. Linn studied the complex salts with **methylamine**, $\text{CoBr}_2 \cdot 6\text{CH}_3\text{NH}_2$; and W. Hieber and co-workers studied the stability of the complex. Similar remarks apply to the complex with **ethylamine**. G. Barbieri and F. Calzolari, and G. Scagliarini and G. Tartarini investigated the complexes formed with **hexamethylenetetramine** or **urotropin**; J. Moitessier, and W. Hieber

and co-workers, the complexes with **phenylhydrazine**; W. Hieber and co-workers, with **ethylenediamine**; J. Frejka and L. Zahlova, with **diaminobutene**; W. Hieber and co-workers, and R. Cernatescu and co-workers, the complex with **phenylenediamine**; G. Spacu, the complex with **benzidine**; and with **toluidine**; W. Hieber and co-workers, the formation of a complex with **aniline**; W. Hieber and F. Leutert, the complex with **acetaldoxime**, with **benzaldoxime**, and with **acetoxime**; and F. Feigl and H. Rubinstein, the complexes with **dimethylglyoxime**. A. Werner and W. Schmujlow found that cobaltous bromide is soluble in **pyridine**; W. R. Brode said that the soln. is rose-red at ordinary temp. and blue when heated. W. R. Brode studied the absorption spectrum, and P. Walden, the mol. conductivity; H. Grossmann, W. Biltz, W. Biltz and B. Fetkenheuer, R. Weinland and co-workers, W. Hieber and co-workers, and A. Hantzsch studied the complexes formed with pyridine; E. G. V. Percival and W. Wardlaw, the complexes with **quinaldine**; and F. Blau, the complexes with **dipyridyl**. E. Beckmann found that cobalt bromide is soluble in **quinoline**, the soln. is rose-red at ordinary temp., and blue when heated. W. R. Brode studied the absorption spectrum, and P. Walden, the mol. conductivity. H. Grossmann and F. Hünseler studied the complex formed with quinoline; F. Blau, the complex formed with **phenanthroline**; and M. R. Menz, the complexes formed with **camphidine**.

G. F. Campbell prepared **cæsium cobaltous tetrabromide**, Cs_2CoBr_4 , from soln. of the component salts with $\text{Cs}:\text{Co}=1:1$ up to a high proportion of the cobalt salt; and **cæsium cobaltous pentabromide**, Cs_3CoBr_5 , from soln. of the component salts with $\text{Cs}:\text{Co}=2:1$ up to $1:1$. The bromides resemble the chlorides. H. Franzen and H. L. Lucking obtained **hydrazonium cobaltous tetrabromide**, $\text{CoBr}_2(\text{N}_2\text{H}_4\cdot\text{HBr})_2\cdot 4\text{H}_2\text{O}$, by mixing soln. of cobaltous bromide and hydrazine bromide. A. Mailhe observed that **copper cobaltous trioxydibromide**, $3\text{CuO}\cdot\text{CoBr}_2\cdot 4\text{H}_2\text{O}$, or, according to A. Werner, $\text{Cu}_2(\text{OH})_4\text{Cu}=(\text{OH}_2\cdots\text{Co}_2\cdot\text{H}_2\text{O})$, is formed in green hexagonal plates, by the action of a soln. of cobalt bromide on copper hydroxide. H. C. Jones and co-workers measured the f.p., the absorption spectrum, and the electrical conductivity of some soln. of calcium and cobalt bromides, and of calcium bromide and cobalt chloride. R. Varet found that with **mercuric cobaltous bromide**, the heat of formation of $\text{CoBr}_2\cdot 2\text{HgBr}_2$ is 3.09 Cals., and of $\text{CoBr}_2\cdot\text{HgBr}_2$, 2.84 Cals. F. Calzolari and U. Tagliavini obtained a complex with hexamethylenetetramine. A. Mailhe obtained **mercuric cobaltous oxybromide**, $6\text{CoO}\cdot\text{CoBr}_2\cdot\text{HgBr}_2\cdot 20\text{H}_2\text{O}$, as a green powder, by the action of a soln. of cobalt bromide on mercuric oxide. B. Rayman and K. Preis prepared **cobaltous stannic hexabromide**, $\text{CoSnBr}_6\cdot 10\text{H}_2\text{O}$ —or, according to G. Spacu and J. Dick, $[\text{Co}(\text{H}_2\text{O})_6][\text{SnBr}_6]\cdot 4\text{H}_2\text{O}$ —in yellowish-green, tabular crystals, by treating a conc. soln. of a cobaltous salt with bromostannic acid. G. Spacu and J. Dick observed complex salts are formed with diethylenediamine piperazine; with hexamethylenetetramine, or urotropine; with benzidine; and with pyridine.

§ 19. Cobaltic Bromide and its Complex Salts

The preparation of **cobaltic bromide**, CoBr_3 , as a chemical individual has not been achieved, yet, as in the case of the cobaltic salts generally, it is remarkable what an extensive variety of stable cobaltic salts can be obtained when the cobalt is associated with other radicles, etc. The general plan of description adopted in the case of the compounds of cobaltic chloride will here be followed, but, since the modes of preparation and several properties are usually similar to those of the corresponding chlorides, many details can be referred back to cobaltic ammoniochlorides.

The CoA_6 or Hexammine Family.

In 1857, F. A. Genth¹ described some properties of **cobaltic hexamminobromide**, $[\text{Co}(\text{NH}_3)_6]\text{Br}_3$; and S. M. Jørgensen prepared this salt by the action of hydrobromic acid on cobaltic hexamminohydroxide. W. Biltz obtained this salt by adding hydrobromic acid to a hot, half-sat. soln. of the hexamminochloride. The rhombic, wine-yellow crystals were also prepared by A. B. Lamb and A. T. Larson. G. Bödtker-Naess and O. Hassel studied the lattice structure. W. Biltz and E. Birk gave 2.340 for the sp. gr. at $25^\circ/4^\circ$, and 171.3 for the mol. vol., and W. Biltz calculated that the mol. vol. of the NH_3 -groups is 18 when that in the corresponding cobaltous salt is 21. The subject was discussed by E. Birk, R. Klement, and F. Ephraim and O. Schütz. W. Biltz observed no marked change in the hexamminobromide at 216° . A. Gordienko, A. N. Nikolopulos, R. Luther and A. N. Nikolopulos, and J. Lifschitz and E. Rosenbohm studied the absorption spectrum. A. Werner and A. Miolati observed that the mol. conductivity, μ , of soln. with a mol of the salt in v litres, at 25° , is :

v	125	250	500	1000	2000
μ	343.8	378.0	401.0	426.9	442.2

and A. B. Lamb and V. Yngve gave for the mol. conductivity and degree of ionization, α , of soln. with C mols per litre :

	0°				25°			
$C \times 10^3$	33.23	6.662	1.336	0.2678	33.23	6.662	1.336	0.2678
μ	174.1	215.3	253.7	272.1	219.1	397.0	461.9	502.5
α	58.6	72.5	85.4	91.6	57.6	77.1	83.4	90.6

The limiting value of $\mu = 297.1$ at 0° , and 553.0 at 25° . P. Pascal gave for the magnetic susceptibility, -0.322×10^{-6} mass unit. E. Rosenbohm, L. C. Jackson, and W. Biltz also studied the magnetic properties of the salt. P. Mosimann, and F. Ephraim and co-workers found that at 18° , a sat. aq. soln. has 2.404 grms., or 0.040 mol per litre. S. M. Jørgensen observed that soln. of the bromide behave towards reagents very much like those of the chloride. According to F. Ephraim, the hexabromide in liquid ammonia at -20° , or in gaseous ammonia at -21° , forms cobaltic enneamminobromide, $[\text{Co}(\text{NH}_3)_9]\text{Br}_3 \cdot 3\text{NH}_3$, and this compound, at -3° , forms cobaltic heptamminobromide, $[\text{Co}(\text{NH}_3)_7]\text{Br}_3 \cdot \text{NH}_3$, and this, at 4.5° to 10° , returns to the hexammine.

F. Ephraim and co-workers observed that the hexamminobromide forms with cadmium bromide **cadmium cobaltic hexamminohexabromide**, $2[\text{Co}(\text{NH}_3)_6]\text{Br}_3 \cdot 3\text{CdBr}_2 \cdot 3\text{H}_2\text{O}$, in yellowish-brown, thin plates which have a sp. gr. of 3.006 at 25° ; and a mol. vol. of 556.4. The sp. gr. of the anhydrous salt is 2.998 at 25° , and the mol. vol., 539.9. F. Ephraim and co-workers obtained **mercuric cobaltic hexamminopentabromide**, $[\text{Co}(\text{NH}_3)_6]\text{Br}_3 \cdot \text{HgBr}_2$, in rectangular plates of sp. gr. 3.365 at 25° , and mol. vol., 226.3; they also obtained **mercuric cobaltic hexamminoenneabromide**, $[\text{Co}(\text{NH}_3)_6]\text{Br}_3 \cdot 3\text{HgBr}_2$, in pale brown needles. They also reported **lead cobaltic hexamminoheptabromide**, $[\text{Co}(\text{NH}_3)_6]\text{Br}_3 \cdot \text{PbBr}_2$, in brown

needles of sp. gr. 2.762 at $25^{\circ}/4^{\circ}$, and mol. vol., 278—but there is some doubt about the individuality of this substance; **lead cobaltic tris-hexamminotridecabromide**, $3[\text{Co}(\text{NH}_3)_6]\text{Br}_3 \cdot 2\text{PbBr}_2$, in orange-brown needles; **lead cobaltic hexamminohenabromide**, $[\text{Co}(\text{NH}_3)_6]\text{Br}_3 \cdot 4\text{PbBr}_2 \cdot 2\text{H}_2\text{O}$, in yellow plates; and **bismuth cobaltic hexamminohexabromide**, $[\text{Co}(\text{NH}_3)_6]\text{Br}_3 \cdot \text{BiBr}_3$, as a pale yellow, flocculent precipitate.

A. Werner and E. Berl, and E. Berl prepared **cobaltic hexahydroxylamine-bromide**, $[\text{Co}(\text{NH}_2\text{OH})_6]\text{Br}_3$, by the action of hydrobromic acid on the hexahydroxylaminechloride. The crystals are a darker yellow than the corresponding chloride. C. S. Borzekowsky prepared the dextro- and lævo-forms of **cobaltic hydroxylaminebisethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)(\text{NH}_2\text{OH})\text{en}_2]\text{Br}_3$.

H. Grossmann and B. Schück,² and L. L. Lehrfeld prepared **cobaltic tris-ethylenediaminebromide**, $[\text{Co en}_3]\text{Br}_3 \cdot 3\text{H}_2\text{O}$, by the aerial oxidation of a soln. of cobaltous bromide in ethylenediamine. The product was thought to be a dihydrate, but this was not confirmed by A. Benrath and W. Kohlberg. A. Werner obtained it by the action of sodium bromide on a soln. of the corresponding chloride; A. Werner and M. Basyrin, by adding sodium bromide to a soln. of the dichlorobisethylenediaminechloride or nitrate in a 10 per cent. aq. soln. of ethylenediamine; and P. Pfeiffer and T. Gassmann, by warming a mol. of chloropentamminochloride with 3 mols. of monohydrated ethylenediamine, dissolving the product in water, and precipitating by the addition of hydrobromic acid. A. Werner recommended the following process:

Dissolve 10 grms. of cobalt chloride in 150 grms. of 10 per cent. ethylenediamine, and oxidize the salt by leading air through the soln. The brown soln. so obtained is acidified with hydrochloric acid, evaporated to crystallization, the crystals dissolved in water, and ammonium nitrate added to the soln., whereby trans-dichloro-diethylenediaminecobaltic nitrate is precipitated. After collecting this salt the filtrate is precipitated with sodium bromide, giving pure trisethylenediaminecobaltic bromide.

The brownish-red or orange-red hexagonal plates or short prisms were found by F. M. Jäger to be pseudo-ditrigonal, with the axial ratio $a : c = 1 : 0.6794$; he added that the crystals are more probably monoclinic, and isomorphous with the corresponding chloride, but with a different cleavage. F. M. Jäger gave 1.845 for the sp. gr. at $25^{\circ}/4^{\circ}$. A. Benrath and W. Kohlberg, and A. G. Berghman measured the vap. press. of the hydrated salt, and the results indicated that the salt is a trihydrate, and that no dihydrate is formed under these conditions—*vide infra*. H. Grossmann and B. Schück gave 271° for the m.p. A. Benrath and W. Kohlberg, and A. G. Berghman studied the vap. press. curves. M. Delépine and R. Charonnet obtained optically active salts. A. Gordienko, T. Inoue, J. Angerstein, W. F. Beyer, and J. Lifschitz and E. Rosenbohm studied the absorption spectrum; and L. C. Jackson, the magnetic properties. E. Rosenbohm gave -1202×10^{-7} mass unit for the magnetic susceptibility. P. Pfeiffer and T. Gassmann observed that the salt is soluble in hot and cold water, and that an aq. soln., sat. at 10° , contains 4.33 per cent. of the anhydrous salt. T. Inoue inferred from the absorption spectrum of aq. soln. that in presence of mercuric salts, a mercuric cobaltic trisethylenediamine bromide is probably formed in soln.

According to A. Werner, a *dextro-salt*, and a *lævo-salt* can be prepared from either the bromide-tartrate or the chloride-tartrate by trituration with warm concentrated hydrobromic acid. The soln., after filtering, deposits large, hexagonal plates, which are probably an acid bromide; on re-crystallization from water, large, columnar crystals of the dextro-bromide, $[\text{Co en}_3]\text{Br}_3 \cdot 2\text{H}_2\text{O}$, are obtained. The lævo-bromide, $[\text{Co en}_3]\text{Br}_3 \cdot 2\text{H}_2\text{O}$, is prepared, in a similar manner, from the gel of lævo-bromide-tartrate or the lævo-chloride-tartrate, the sparingly-soluble, inactive, or racemic bromide remains undissolved. According to F. M. Jäger, the dextro-salt forms brownish-red, thick, prismatic crystals with well-developed faces, whilst the crystals of the lævo-salt are dodecahedrons. The axial ratio of the bipyramidal, tetragonal crystals is $a : c = 1 : 0.8399$; and the sp. gr. is 1.971 at $25^{\circ}/4^{\circ}$. J. Angerstein, and J. Lifschitz and E. Rosenbohm found that aq. soln. of the optically inactive form and the two active forms have the same absorption spectrum. The

sp. rotation of a 1 per cent. soln. was found by A. Werner to be $[\alpha] = 117^\circ$ for the dextro-salt, and -115° for the lævo-salt. Observations were also made by W. Kuhn and E. Bein, F. M. Jäger, A. P. Smirnof, and J. Lifschitz and E. Rosenbohm. The magnetic properties were examined by E. Rosenbohm, and L. C. Jackson. A. Werner said that the optically-active forms are more soluble than the inactive forms. G. and P. Spacu obtained **mercury cobaltic trisethylene-diaminebromide**, $[\text{Co en}_3]\text{HgBr}_5$.

P. Pfeiffer and T. Gassmann prepared **cobaltic trispropylenediaminebromide**, $[\text{Co pn}_3]\text{Br}_3 \cdot \text{H}_2\text{O}$, in small, yellow crystals, by adding hydrobromic acid to an aq. soln. of the corresponding chloride. A sat., aq. soln. at 16° contains 0.808 grm. per c.c. of the anhydrous bromide. The absorption spectra of aq. soln. were studied by J. Lifschitz and E. Rosenbohm. E. Rosenbohm gave -4.34×10^{-7} mass unit for the magnetic susceptibility of the solid. The magnetic properties were also studied by L. C. Jackson. The dihydrated *dextro-salt* and the *lævo-salt* were prepared by A. P. Smirnof, and their optical properties studied by J. Lifschitz and E. Rosenbohm, J. Lifschitz, and L. Tschugaeff and W. Sokoloff. J. Frejka and L. Zahlova prepared **cobaltic tris-butylene-diaminebromide**, $[\text{Co bn}_3]\text{Br}_3$. G. and P. Spacu prepared complexes with hexamethylenetetrammine, $[\text{Co h}_6](\text{SnBr}_6)$; with pyridine, $[\text{Co py}_6](\text{SnBr}_6)$; and with piperidine, $[\text{Co pd}_3](\text{SnBr}_6) \cdot 6\text{H}_2\text{O}$. G. Spacu and R. Ripon prepared some complex pyridine salts.

A. Werner and C. Kreutzer,³ K. R. Lange, and A. Werner prepared **cobaltic cis-bisethylenediaminediamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{en}_2]\text{Br}_3$, by treating the corresponding iodide with freshly-precipitated silver oxide, and saturating the filtrate with hydrobromic acid. The orange crystals, unlike the corresponding trans-salt, are freely soluble in water. A. Werner and Y. Shibata separated the *dextro-salt*, and the *lævo-salt* from the corresponding camphor bromosulphonates. The yellow, acicular crystals are freely soluble in water. The sp. rotation of a 1 per cent. aq. soln. of the dextro-salt is $[\alpha] = 37^\circ$, and for the lævo-salt, $[\alpha] = -37^\circ$. A. Werner and co-workers also prepared **cobaltic trans-bisethylenediaminediamminobromide** by the action of liquid ammonia on the dichloro-bisethylenediaminechloride, and treating the soln. with sodium bromide; by treating a trans- $[\text{Co}(\text{NH}_3)_2\text{en}_2(\text{CNS})]$ -salt, or a trans- $[\text{Co en}_2(\text{CNS})_2]$ -salt with perhydrol, and afterwards with hydrobromic acid; or by the action of potassium bromide on the corresponding chloride. Y. Shibata measured the absorption spectrum.

W. Kuhn and K. Bein studied the absorption spectrum of **cobaltic trisphenylenediaminechloride**, $[\text{Co pn}_3]\text{Br}_3$. A. Werner and K. Dawe prepared **cobaltic bispropylenediaminediamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{pn}_2]\text{Br}_3 \cdot \text{H}_2\text{O}$, in golden-yellow needles, by adding an excess of hydrobromic acid to a boiling, conc. soln. of the corresponding chloride. F. M. Jäger and H. B. Blumendal obtained **cobaltic ethylenediaminobis-cyclopentanediaminebromide**, $[\text{Co en}(\text{C}_5\text{H}_{12}\text{N}_2)_2]\text{Br}_3 \cdot \text{H}_2\text{O}$, by treating the iodide with sodium bromide. P. Pfeiffer and T. Gassmann, by heating the cis- or trans-dichlorobisethylenediaminechloride with monohydrated propylenediamine on a water-bath, and then adding conc. hydrobromic acid. E. Rosenbohm, and L. C. Jackson studied the magnetic properties. F. M. Jäger and H. B. Blumendal prepared **cobaltic bisethylenediamine-trans-cyclopentanediaminebromide**, $[\text{Co en}_2(\text{C}_5\text{H}_{12}\text{N}_2)]\text{Br}_3 \cdot \text{H}_2\text{O}$, by treating the corresponding chloride with sodium bromide. They also prepared the *dextro-salt*, and the *lævo-salt*, as well as **cobaltic bisethylenediamine-1-cyclopentanediaminebromide**, $[\text{Co en}_2(1\text{-C}_5\text{H}_{12}\text{N}_2)]\text{Br}_3 \cdot 2\text{H}_2\text{O}$, and the *dextro-salt*. M. F. Jäger prepared **cobaltic bisethylenediamine- α -phenanthroline bromide**, $[\text{Co en}_2(\text{C}_{12}\text{H}_8\text{N}_2)]\text{Br}_3$, by treating the corresponding iodide with silver bromide. W. Tupizina, R. Plischke, and W. A. Redeker prepared **cobaltic pyridinebisethylenediamineaminobromide**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{py}]\text{Br}_3$. C. J. Dippel and F. M. Jäger prepared **cobaltic trisdiaminopentanebromide**, $[\text{Co pt}_3]\text{Br}_3$; and **cobaltic bisethylenediaminodiaminepentane**, $[\text{Co en}_2\text{ptn}]\text{Br}_3$, with $\alpha\beta$ - and $\beta\beta$ -diaminopentane. G. Spacu and J. Dick prepared **cobaltic quinquesbenzidinopyridinohydroxybromostannate**, $[\text{Co bzd}_5\text{py}][\text{SnBr}_5(\text{OH})]5\text{H}_2\text{O}$; J. C. Duff, **cobaltic succinatobisethylenediaminobromide**.

S. M. Jörgensen⁴ prepared **cobaltic roseobromide**, or **cobaltic aquopentamminobromide**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{Br}_3$, by adding hydrobromic acid to an aq. or ammoniacal soln. of the nitrate; and A. Werner, by slowly adding hydrobromic acid to a boiling ammoniacal soln. of chloropentamminochloride, and then alcohol. The flesh-red powder is washed with alcohol and ether. The red octahedra, or rhombic plates were found by F. Ephraim and O. Schütz to have a sp. gr. of 2.269 at 25° , and a mol. vol., 177.1, corresponding with a vol. contraction of 59.2 per cent. during its formation. A. B. Lamb and J. W. Marden found the vap. press. at 25° is about 4 mm. The salt may be kept a long time, but S. M. Jörgensen found that it loses water rapidly at 100° , and forms bromopentamminobromide. A. B. Lamb and J. P. Simmons calculated -9.22 Cals. for the mol. heat of solution at 25° . The

lowering of the f.p. of aq. soln. was studied by J. Petersen; the absorption spectrum, by A. N. Nikolopoulos, R. Luther and A. N. Nikolopoulos, and J. Angerstein. A. Werner and A. Miolati gave for the mol. conductivity, μ , of soln. of a mol of the salt in v litres, at 25°:

v	125	250	550	1000	2000
μ	333.6	365.4	390.3	412.9	436.4

Measurements were also made by Y. Shibata. J. Petersen calculated the degrees of ionization, α , of the salt, from the eq. conductivity of soln. with 4, 50, and 1000 gram-equivalents per litre, at 18°, to be, respectively, $\alpha=0.58, 0.82$, and 0.98 . The polarization tension was studied by N. R. Dhar and G. Urbain—*vide supra*, the hexamminochloride. F. Ephraim observed that a sat., aq. soln. at 17.5° contains 0.364 mol per litre. A. B. Lamb and J. W. Marden found that a 0.01302*M*-soln. of aquopentamminobromide or bromopentamminobromide in 0.02*M*-HBr, contains after 30 hrs' heating at 70°, 98 per cent. of aquopentamminobromide, no matter which salt was employed at the start. F. Ephraim observed that ammonia acts on the bromide at -21°, forming a bluish-red **cobaltic aquopentadecamminobromide**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{Br}_3 \cdot 10\text{NH}_3$, and when heated to 21°, a series of solid soln. is formed until, at the limit, **cobaltic aquooctamminobromide**, $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{Br}_2 \cdot 3\text{NH}_3$, is produced, and this product is stable up to 90°. The solid soln. at 8° has the composition: $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{Br}_3 \cdot 8\text{NH}_3$. For the chemical reactions, *vide supra*, the corresponding chloride. Some double salts have been reported.

F. Ephraim and P. Mosimann were unable to prepare **zinc cobaltic aquopentamminobromide**, but they obtained **cadmium cobaltic aquopentamminobromide**, $2[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{Br}_3 \cdot 3\text{CdBr}_2$, easily soluble in water. The dark red, tabular crystals of the sat. soln. were found by F. Ephraim and O. Schütz to have a sp. gr. of 2.961 at 25°, and a mol. vol. of 547.3, corresponding with a vol. contraction of 48.8 per cent. during the formation of the salt. F. Ephraim and P. Mosimann prepared **mercuric cobaltic aquopentamminobromide**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{Br}_3 \cdot \text{HgBr}_2$, in pale red, acicular crystals, which F. Ephraim and O. Schütz found to have the sp. gr. 3.279 at 25°, and the mol. vol. 232.5, corresponding with a vol. contraction of 53.7 per cent. in the formation of the compound. F. Ephraim and P. Mosimann also prepared **mercuric cobaltic aquopentamminobromide**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{Br}_3 \cdot 3\text{HgBr}_2$; and F. Ephraim and O. Schütz found the sp. gr. to be 4.144 at 25°, and the mol. vol., 357.8, corresponding with a vol. contraction of 44.0 per cent. in the formation of the compound. E. Birk also studied the vol. relations of these salts. F. Ephraim and P. Mosimann were unable to prepare **lead cobaltic aquopentamminobromide**. H. Seibt, and A. Werner prepared the *cis*- and *trans*-forms of **cobaltic aquobisethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{en}_2(\text{H}_2\text{O})]\text{Br}_3 \cdot \text{H}_2\text{O}$, by the action of potassium hydroxide or of freshly-precipitated silver oxide on the stereoisomeric cobaltic chloro- and bromo-bisethylenediamineammino salts. In every case, partial transformation takes place, so that a mixture of the isomerides is produced. The product of action of the alkali is an hydroxoammine salt, the aquoammine salt being produced when the soln. is acidified. Potassium hydroxide produces a greater relative transformation than silver oxide; more of the *trans*-isomeride is produced at low than at ordinary temp. The mixture of the isomerides is separated by taking advantage of the fact that the *trans*-salt is much less soluble in dil. hydrobromic acid than the *cis*-salt. The isomerides can be distinguished from each other (i) by transformation into the chloroamminodithionate by warming with hydrochloric acid, and subsequent precipitation with sodium dithionate; (ii) by warming the aq. soln., to which sodium nitrite and a little acetic acid has been added, to 60° to 70°. A yellow soln. is produced, which, on the addition of sodium dithionate, gives an insoluble precipitate if the *cis*-isomeride is present, or a precipitate which can be re-crystallized from water if the *trans*-isomeride is present. The *trans*-form gives brick-red acicular crystals, and the *cis*-form gives aggregates of small, red crystals. A. Gordienko studied the absorption spectrum. M. Rosner prepared **cobaltic aquobispyridinetriamminobromide**, $[\text{Co}(\text{NH}_3)_3\text{py}_2(\text{H}_2\text{O})]\text{Br}_3$.

S. M. Jörgensen⁵ prepared **cobaltic diaquotetramminobromide**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]\text{Br}_3$, by adding 1:1-hydrobromic acid to a soln. of carbonatotetramminobromide, in 10 times its weight of cold water, until the evolution of carbon dioxide had ceased, and then adding conc. hydrobromic acid to the well-cooled liquid. The separation of dark red, octahedral crystals is almost quantitative. At 100°, the salt loses, in 30 mins., 1 mol. of water, and passes into the greyish-

violet aquobromotetramminobromide, and A. Werner, and F. Ephraim observed that the same transformation occurs when the solid is kept for some time, or if it be allowed to stand in contact with its soln. in 25 per cent. hydrobromic acid. A. Werner and A. Miolati found that the mol. conductivity, μ , of a soln. of a mol of the salt in v litres, at 25° , to be :

v	125	250	500	1000	2000
μ	325.5	354.8	379.8	399.5	417.4

The subject was studied by Y. Shibata. F. Ephraim found that a sat., aq. soln. at 22° , has 1.67 mols of the salt per litre. S. M. Jörgensen noted that with potassium ferri cyanide, or cobalticyanide, the corresponding salts are precipitated from the aq. soln. Likewise with hydrochloroplatinic acid; and with hydrochloroauric acid and dil. sulphuric acid, a sulphatobromoaurate is precipitated.

E. Schmidt, and A. Werner and co-workers prepared **cobaltic cis-diaquobisethylenediaminebromide**, $[\text{Co en}_2(\text{H}_2\text{O})_2]\text{Br}_3 \cdot 2\text{H}_2\text{O}$, analogous with the bromide, starting from the carbonatobisethylenediaminebromide. J. C. Duff and E. J. Bills also prepared the salt in a similar manner. K. R. Lange, and A. Werner and co-workers observed that the red crystals pass, on keeping, into the violet *cis*-dibromo-bisethylenediaminebromide, and in the presence of acids, into the green *trans*-dibromo-salt. Four mols. of water are lost at 115° , and the green dibromo-salt is formed. The compound forms a yellowish-red, aq. soln. with an acidic reaction. Pyridine or potash-lye converts it into the *cis*-aquobromide. A. Werner and co-workers also prepared **cobaltic diaquobisethylenediaminebromide**, $[\text{Co en}_2(\text{H}_2\text{O})_2]\text{Br}_3 \cdot 2\text{H}_2\text{O}$, by the action of conc. hydrobromic acid on dinitratobisethylenediamine thiocyanate, or on the hydroxyaquobisethylenediaminebromide. The pale violet-brown crystals form with water a dark reddish-brown soln., with an acidic reaction. On keeping, the salt goes into the violet *cis*-dibromobromide, and if an acid is present, green *trans*-dibromobromide is formed. The salt is dihydrated at 115° , forming the green *trans*-dibromobromide with a little of the *cis*-salt. A. Werner also prepared **cobaltic diaquobispyridinediamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{H}_2\text{O})_2]\text{Br}_3 \cdot 2\text{H}_2\text{O}$, by the action of hydrobromic acid on the hydroxyaquobispyridinediamminochloride. The yellowish-brown, tabular crystals form, with a large proportion of water, a brownish-red soln. with an acidic reaction, and with a small proportion of water, or alcohol, hydroxyaquobispyridinediamminobromide.

The CoA₅ or Pentammine Family.

S. M. Jörgensen⁶ prepared **cobaltic bromopentamminobromide**, $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{Br}_2$, by oxidizing an ammoniacal soln. of cobaltous bromide with air, and heating the soln. on a water-bath; or else by the action of hydrobromic acid on aquopentamminohydroxide, sulphate, or oxalate. The dichroic, bluish-violet, octahedral crystals are almost black, and the sp. gr. is 2.483 at $18^\circ/4^\circ$. F. Ephraim gave 2.486 for the sp. gr. at 25° , and 154.4 for the mol. vol.; R. Klement, sp. gr. 2.512 at $25^\circ/4^\circ$, and mol. vol., 152.9 ; and R. Lorenz and I. Posen, and I. Posen, in vacuo, 2.4739 , and mol. vol. at absolute zero, 150.5 . The vol. contraction in the formation of the salt was also studied by E. Birk, and W. Biltz. E. N. Gapon studied the diffusion. A. B. Lamb and J. P. Simmons gave -12.663 Cals. for the mol. heat of soln. at 25° . A. N. Nikolopulos, R. Luther and A. N. Nikolopulos, and J. Angerstein studied the absorption spectrum. A. Werner and A. Miolati found the mol. conductivity, μ , for soln. with a mol of the salt in v litres, at 25° , to be :

v	250	500	1000	2000
μ	230.5	244.7	257.6	268.1

Observations were also made by Y. Shibata. A. B. Lamb and J. W. Marden found that for soln. with 0.003266 mol per litre, at 25° , the value of μ rose from 260.1 after 34 mins., to 287.2 after 1310 mins., to 353.1 after 2710 mins.; and, in the steady state, 402.0 . The velocity constant for the transformation of the salt into aquopentamminobromide in these soln. was calculated by A. B. Lamb and J. W. Marden for a unimolecular reaction so that $k=0.000170$. J. N. Brønsted and R. Livingston said that the speed of aqution is almost independent of the initial concentration of the complex ions, but is dependent on the H^+ -ion concentration. A. B. Lamb and J. W. Marden observed that the reaction is almost com-

plete at 70°, for a 0.01302*M*-soln. in 0.02*M*-HBr, after 24 hrs., contained 98.10 per cent. of aquopentamminobromide. A. B. Lanib and J. P. Simmons found the mol. heat of this transformation is 1.69 Cals. at 25°. E. N. Gapon studied the ionic mobility; and N. R. Dhar and G. Urbain, the polarization tension—*vide supra*, the hexamminochloride. S. M. Jörgensen said that at 16°, 1 part of the salt requires 530 parts of water for its dissolution; F. Ephraim gave for a sat. soln. at 20°, 0.00614 mol per litre; and J. N. Brönsted and A. Petersen, 0.00275 mol per litre at 0°. The effect of salts on the solubility of bromopentamminobromide in water, and in methanol, was studied by J. N. Brönsted and co-workers. F. Ephraim said that the salt is virtually insoluble in hydrobromic acid, or in aq. soln. of ammonium or potassium bromide, as well as in alcohol. H. Freundlich and R. Bartels studied the hydrolysis of the salt. S. M. Jörgensen observed that a cold, freshly-prepared aq. soln. forms the corresponding salt of the series when it is treated with dil. nitric acid, dil. hydrochloric acid, potassium iodide, chromic acid, hydrochloroplatinic acid, or sodium bromoplatinate; silver chloride converts it into the chloride of the series; and silver oxide, carbonate, or nitrate produce the hydroxide and salts of aquopentammine, respectively. F. G. Soper studied the speed of the reaction with a mercuric salt.

S. M. Jörgensen prepared lilac needles of **mercuric cobaltic bromopentamminooctobromide**, $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{Br}_2 \cdot 3\text{HgBr}_2$; and violet needles of **mercuric cobaltic bromopentamminobromoheptachloride**, by allowing a warm soln. of the bromopentamminobromide to run into an excess of a soln. of mercuric chloride; and if the bromopentamminobromide soln. be run into an excess of a soln. of sodium mercuric chloride, $[\text{Co}(\text{NH}_3)_5\text{Br}]_2\text{Cl}_3\text{Br} \cdot 6\text{HgCl}_2$, is formed in violet needles, and there is evidence of the formation of solid soln.

S. M. Jörgensen obtained **cobaltic bromopentamminodichloride**, $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{Cl}_2$, by treating a cold, aq. soln. of the bromide with dil. hydrochloric acid, or by pouring a soln. of the bromide in water at 40° into conc. hydrochloric acid. The dark, octahedral crystals are dichroic—violet to yellowish-red; the sp. gr. is 2.095 at 17°/4°; F. Ephraim and O. Schütz gave 2.087 at 25°, and the mol. vol. 141.3; R. Klement, 2.089 for the sp. gr. at 25°, and 141.3 for the mol. vol. E. Birk, and W. Biltz studied the vol. contraction in the formation of the compound. S. M. Jörgensen observed that the salt is sparingly soluble in cold water, but is more soluble than the bromide. F. Ephraim found that a sat. soln. at 20° has 0.0106 mol per litre; and J. N. Brönsted and co-workers found, at 0°, 0.00542 mol per litre, and at 20°, 0.011 mol; they also measured the solubility in the presence of other salts in aq. and in methanol soln. The heat of the transformation: $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{Cl}_2 + [\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Br}_2 = [\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2 + [\text{Co}(\text{NH}_3)_5\text{Br}]\text{Br}_2$, is 621 cals. at 0°. S. M. Jörgensen said that the salt is insoluble in dil. hydrochloric acid, and in alcohol. The cold, sat. soln. gives crystalline precipitates with dil. hydrobromic acid, hydrofluosilicic acid, sodium dithionate, ammonium oxalate, potassium dichromate, and potassium mercuric iodide. It forms violet needles of **mercuric cobaltic bromopentamminooctochloride**, $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{Cl}_2 \cdot 3\text{HgCl}_2$, when the nitrate of the series is treated with sodium mercuric chloride. E. Berl prepared **cobaltic bromobisethylenediaminehydroxylamine chloride**, $[\text{Co}(\text{NH}_2\text{OH})\text{en}_2\text{Br}]\text{Cl}_2$.

H. Seibt prepared **cobaltic fluobisethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)\text{en}_2\text{F}]\text{Br}_2$. S. M. Jörgensen prepared **cobaltic chloropentamminodibromide**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Br}_2$, by treating the corresponding sulphate or nitrate with sodium bromide; by treating an aq. soln. of the carbonate with conc. hydrobromic acid; or by dissolving the chloride in dil. sulphuric acid at 50°, and pouring the cold soln. into well-cooled hydrobromic acid. H. Pitzler studied the equilibrium condition in the system: $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2 + 2\text{HBr} \rightleftharpoons [\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Br}_2 + 2\text{HCl}$. According to S. M. Jörgensen, the reddish-violet crystals have a sp. gr. 2.15 at 25°, and a mol. vol. of 157.3; R. Klement gave 2.244 for the sp. gr. at 25°/4°, and 151.2 for the mol. vol. The vol. contraction in the formation of the compound was also studied by E. Birk, and W. Biltz. The absorption spectrum was studied by A. N. Nikolopoulos, R. Luther and A. N. Nikolopoulos, and J. Angerstein. A. Werner

and A. Miolati found the mol. conductivity, μ , of soln. of a mol of the salt in v litres of water, at 25° , to be :

v	128	256	512	1025	2048
μ	232.5	247.7	259.3	270.0	275.6

F. Ephraim found that a sat., aq. soln. at 19° contained 0.0178 mol per litre, and J. N. Brönsted and A. Petersen, at 0° , 0.00725 mol per litre. J. N. Brönsted studied the effect of other salts on the solubility in water, and in methanol. F. Ephraim observed on the solubility in water, and in methanol. F. Ephraim observed that no ammonia is taken up by the salt at -21° . S. M. Jörgensen prepared the complex: $4[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Br}_2 \cdot 9\text{HgBr}_2$. There is here evidence of the formation of solid soln.

E. Schmidt, and A. Werner prepared optically inactive or racemic **cobaltic-cis-bromobisethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Br}]\text{Br}_2 \cdot 2\text{H}_2\text{O}$, by evaporating cis-nitrato-bisethylenediamineamminothiosulphate, with conc. hydrobromic acid; and A. Werner and W. E. Boës, and A. Werner and E. Scholze, by warming trans-dibromobisethylenediaminebromide with 1:1 aq. ammonia; or by warming diaquo-tetrol-quaterethylenediaminesulphate with a soln. of ammonium bromide, and then salting out the compound with sodium bromide. The *dihydrate* forms dark reddish-violet, rhombic crystals, and the anhydrous salt, dark brownish-red, prismatic crystals. The absorption spectrum was studied by A. Gordienko, Y. Shibata, and Y. Shibata and G. Urbain; and the magnetic properties, by L. C. Jackson, and W. Biltz. E. Rosenböhme gave, -2.64×10^{-7} mass unit for the magnetic susceptibility. A. Werner and E. Scholze obtained the *dextro-salt*, and the *levo-salt* from the corresponding camphor bromosulphonates. The sp. rotation of a 1 per cent. soln. of the *d*-salt is $[\alpha] = 46.25^\circ$, and for the *l*-salt, -45° . A. Werner, and A. Werner and Y. Shibata found that liquid ammonia converts the active bromide into the corresponding active cis-bisethylenediaminediamminobromide, accompanied by a little of the trans-salt. E. Rosenböhme gave -3.44×10^{-7} mass unit for the magnetic susceptibility. A. Werner, and A. Werner and W. E. Boës also prepared dark violet, prismatic crystals of **cobaltic trans-bromobisethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Br}]\text{Br}_2 \cdot 2\text{H}_2\text{O}$, by the action of hydrobromic acid on the corresponding dithionate, or on an aq. soln. of trans-aquobisethylenediamineamminobromide; or by treating trans-thiocyanatobisethylenediamineamminobromide, first with conc. nitric acid, and then with hydrobromic acid. C. S. Borzekowsky prepared the *dextro*- and *levo*-forms of **cobaltic bromohydroxylaminebisethylenediaminebromide**, $[\text{Co}(\text{NH}_2\text{OH})\text{en}_2\text{Br}]\text{Br}_2$, as well as **cobaltic bromohydroxylaminebisethylenediaminechloride**, $[\text{Co}(\text{NH}_2\text{OH})\text{en}_2\text{Br}]\text{Cl}_2$.

H. Seibt prepared **cobaltic cis-fluobisethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{F}]\text{Br}_2$, by adding sodium bromide to a conc., aq. soln. of the corresponding fluoride. A. Gordienko, and J. Lifschitz and E. Rosenböhme studied the absorption spectrum. H. Seibt also prepared **cobaltic trans-fluobisethylenediamineamminobromide**, by treating the corresponding fluoride with ammonium fluoride. E. Berl obtained **cobaltic chlorobisethylenediaminehydroxylaminebromide**, $[\text{Co}(\text{NH}_2\text{OH})\text{en}_2\text{Cl}]\text{Br}_2$, and a double salt with platinous chloride.

A. Werner prepared bluish-red, optically-active or racemic **cobaltic cis-chlorobisethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Cl}]\text{Br}_2$, by treating with conc. hydrobromic acid a soln. of *cis*-chloroaquobisethylenediaminesulphate in conc. aq. ammonia—some *trans*-bisethylenediaminediamminobromide is formed at the same time. The salt is also prepared by salting out with sodium bromide a soln. of trans-dichlorobisethylenediaminechloride in liquid ammonia. The absorption spectrum was studied by J. Angerstein, and A. Gordienko. A. Werner and V. L. King treated the optically-active camphor bromosulphonates with sodium dithionate, and then acted on the product with hydrobromic acid. They thus obtained the *dextro-salt*, and the *levo-salt* in cherry-red, tabular crystals. The sp. rotation of 1 per cent. soln. had, with the C-line, the $[\alpha] = 43.1^\circ$ for the *d*-salt, and -43.0° for the *l*-salt. The salt is stable in aq. soln. and shows no sign of racemization at 70° . L. A. Welö gave -0.292×10^{-6} for the magnetic susceptibility of the *d*-salt, and -0.035×10^{-6} for the *l*-salt.

J. Meisenheimer and E. Kiderlen prepared violet plates of **cobaltic trans-chloroallylaminebisethylenediaminebromide**, $[\text{Co en}_2(\text{C}_3\text{H}_5\text{NH}_2)\text{Cl}]\text{Br}_2$, by the action of potassium bromide on the chloride. This salt is less soluble in water than the corresponding chloride; they also prepared reddish-violet, six-sided prisms of **cobaltic chloroallylaminebisethylenediaminebromide**, $[\text{Co en}_2(\text{C}_3\text{HNH}_2)\text{Cl}]\text{Br}_2 \cdot \frac{1}{2}\text{H}_2\text{O}$, in a similar manner; likewise reddish-violet, six-sided prisms of **cobaltic chloroanilinebisethylenediaminebromide**, $[\text{Co en}_2(\text{C}_6\text{H}_5\text{NH}_2)\text{Cl}]\text{Br}_2 \cdot \frac{1}{2}\text{H}_2\text{O}$; also brownish-red, and violet-red plates of **cobaltic chloro-*p*-toluidinebisethylenediaminebromide**, $[\text{Co en}_2(\text{C}_7\text{H}_7\text{NH}_2)\text{Cl}]\text{Br}_2$; and lilac **cobaltic chlorobenzylaminebisethylenediaminebromide**, $[\text{Co en}_2(\text{C}_7\text{H}_7\text{NH}_2)\text{Cl}]\text{Br}_2 \cdot \frac{1}{2}\text{H}_2\text{O}$. R. Vogel prepared **cobaltic chloropyridinebisethylenediaminebromide**, $[\text{Co en}_2\text{pyCl}]\text{Br}_2$.

A. Werner obtained **cobaltic hydroxypentamminobromide**, $[\text{Co}(\text{NH}_3)_5(\text{OH})]\text{Br}_2$.

H₂O, by heating aquopentamminobromide with conc. hydrobromic acid, and precipitating the salt with alcohol. The bluish-red salt is readily soluble in water, and the bluish-red soln. has an alkaline reaction. The absorption spectrum was studied by J. Angerstein. A. Werner, and K. R. Lange also obtained **cobaltic hydroxyaquotetramminobromide**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{OH})]\text{Br}_2$, in carmine-red crystals, by saturating a soln. of the chloride with potassium bromide. H. J. S. King found the eq. conductivity, at 0°, to be :

ν	64	128	256	512	1024	∞
λ	116.3	123.7	129.6	134.7	137.0	146.9

A. Oswald studied the physiological action.

M. Rosner prepared **cobaltic hydroxybispyridinetriamminobromide**, $[\text{Co}(\text{NH}_3)_3\text{py}_2(\text{OH})]\text{Br}_2 \cdot 2\text{H}_2\text{O}$. A. Werner, and A. Werner and S. Matissen prepared **cobaltic cis-hydroxy-aquobisethylenediaminebromide**, $[\text{Co en}_2(\text{H}_2\text{O})(\text{OH})]\text{Br}_2 \cdot \text{H}_2\text{O}$, by warming cis-hydroxy-bromobisethylenediaminebromide with a little water; by the action of pyridine in aq. soln. on diaquobisethylenediaminebromide, by the action of dil. potash-lye on green or violet trans-dichlorobisethylenediaminechloride, followed by treatment with conc. hydrobromic acid; or by the action of potash-lye on a soln. of carbonatobisethylenediaminebromide in dil. nitric acid and subsequent treatment with sodium bromide. The bluish-red crystalline powder decomposes at 115°. It is less soluble in water than the corresponding chloride. Potassium bromide and iodide precipitate the corresponding salts from the aq. soln.; silver nitrate precipitates silver bromide free from silver oxide; and conc. hydrochloric or hydrobromic acid forms cis-diaquobisethylenediaminebromide; carbon dioxide acts on the aq. soln. forming a carbonatobromide. The boiling aq. soln. decomposes, forming trisethylenediaminebromide, and hexol-sexiesethylenediaminebromide. The magnetic properties were studied by L. C. Jackson; and E. Rosenbohm gave -3.09×10^{-7} mass unit for the magnetic susceptibility. A. Werner also prepared **cobaltic trans-hydroxyaquobisethylenediaminebromide**, by warming trans-diaquobisethylenediaminebromide with conc. aq. ammonia; by boiling the cis-salt with 1:1-potash-lye, and then neutralizing the ice-cold liquor with hydrobromic acid; by triturating a soln. of cis-dichlorobisethylenediaminechloride with solid sodium bromide; and by warming trans-dibromobisethylenediaminebromide with dil. aq. ammonia until red crystals began to form. The pale bluish-red crystals are less soluble in water than the corresponding chloride. The mol. wt. by the f.p. method is 139. L. C. Jackson studied the magnetic properties, and E. Rosenbohm gave -3.09×10^{-7} mass unit for the magnetic susceptibility. A. Werner found that carbon dioxide, led into the ice-cold soln., forms carbonatobisethylenediaminebromide.

A. Werner reported **cobaltic hydroxyaquobispyridinediamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{H}_2\text{O})(\text{OH})]\text{Br}_2$, by the addition of potassium bromide to an acetic acid soln. of the corresponding chloride; by mixing a sat. soln. of diaquobispyridinediamminochloride with potassium bromide, or by treating the corresponding bromide with water, or by adding hydrobromic acid to the aq. soln. The small, violet crystals are sparingly soluble in water, and the soln. reacts feebly alkaline.

A. Werner⁷ prepared **cobaltic cis-chloroaquotetramminobromide**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2\text{Cl}]\text{Br}_2$, by simply keeping cis-diaquotetramminobromide for a long time; and S. M. Jörgensen, by adding a sat., aq. soln. of the corresponding chloride to ice-cold, conc. hydrobromic acid. The bluish-violet crystals are more soluble in water than is the corresponding chloride, and almost insoluble in 1:1-hydrobromic acid.

A. Werner, and A. Werner and G. Tschernoff obtained **cobaltic chloroaquobisethylenediaminebromide**, $[\text{Co en}_2(\text{H}_2\text{O})\text{Cl}]\text{Br}_2 \cdot \text{H}_2\text{O}$, by triturating the corresponding sulphate with conc. hydrobromic acid, and precipitating the salt with hydrobromic acid from ice-cold soln. A. Gordienko measured the absorption spectrum. A. Uspensky and K. Tschibisoff noticed that when the soln. of the salt in conc. hydrobromic acid is evaporated, a complex mixture containing cis- and trans-bromochlorobisethylenediaminebromide, and trans-dibromobisethylenediaminebromide is formed. H. Fischlin, and A. Werner and J. E. Schwyzer prepared the *dextro*-salt, and the *levo*-salt from the corresponding camphor-bromosulphonates. The sp. rotation of a 1 per cent. soln. of the *d*-salt is $[\alpha] = 215^\circ$, and of the *l*-salt, -215° . H. Fischlin, and J. Lifschitz studied the rotary dispersion. Conc. aq. ammonia transforms these salts into active chlorohydroxy-salts; and with acetylacetone or propionylacetone, A. Werner and J. E. Schwyzer observed that optically active acetylacetonatobisethylenediamine or propionylacetonatobisethylenediamine-salts are formed.

A. Werner prepared **cobaltic chlorodiaquotriaminobromide**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_2\text{Cl}]\text{Br}_2$, by pouring an ice-cold soln. of the corresponding chloride into cold, conc. hydrobromic acid, and draining the precipitate on porous tiles. The small, dark blue needles can be preserved over potassium hydroxide, but the salt is very unstable. In air, it forms bromochloro-aquotriaminobromide. It forms a blue soln. in water, and from the ice-cold soln., hydrobromic acid precipitates the monohydrate of bromochloro-aquotriaminobromide.

A. Werner, and A. Werner and A. Wolberg prepared **cobaltic bromoaquo-tetramminobromide**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Br}]\text{Br}_2$, by keeping cis-diaquotetramminobromide for some time; or by adding alcohol to an aq. soln. of dibromotetramminobromide acidulated with hydrobromic acid, at 40° ; W. Schramm, by the action of malonic acid on trans-dibromotetramminobromide; and A. Werner and A. Miolati, by treating bromocarbonatotetramminobromide with hydrobromic acid. The brownish-violet prisms form a violet, aq. soln. which soon changes to a rose-colour owing to aquation. A. Werner and A. Miolati found that the mol. conductivity, μ , for a mol of the salt in v litres of water, at 25° , is:

v	125	250	500	1000	2000
μ	320.4	349.4	377.3	395.4	413.6

and they added that the results agree with those obtained with diaquotetramminobromide. A. Werner and A. Wolberg observed that ammonium thiocyanate converts the salt into what is probably a thiocyanatotetrammine; and W. Schramm, that oxalic acid forms oxalatotetrammine, and malonic acid forms a trace of dibromotetramminobromide. A. Werner and A. Wolberg found that by digesting this salt with conc. hydrochloric acid of sp. gr. 1.17, small, violet prisms of **cobaltic bromoaquotetramminochloride**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Br}]\text{Cl}_2 \cdot \frac{1}{2}\text{H}_2\text{O}$, are formed. J. Angerstein studied the absorption spectrum.

E. Schmidt, and A. Werner and R. Schmidt prepared **cobaltic bromoaquobisethylenediaminebromide**, $[\text{Co en}_2(\text{H}_2\text{O})\text{Br}]\text{Br}_2 \cdot \text{H}_2\text{O}$, by the following methods: (1) A soln. of neutral trans-dichlorobisethylenediaminechloride containing nitric acid is heated with a conc. soln. of silver nitrate until it assumes a Bordeaux-red colour. After collecting the silver bromide, the filtrate is saturated with sodium bromide, first filtering off any more silver bromide which may be formed. After a few hours, the bromide has deposited as a violet, microcrystalline powder. (2) A conc. soln. of the *trans*-dibromo-bromide is heated at 40° until it becomes violet in colour; after cooling, it is saturated with sodium bromide. Any green crystals of dichloro-bromide which are precipitated with the bromoaquo-bromide are removed by fractional soln. in ice-cold water, the dichloro-bromide being the less-soluble salt. (3) A soln. of the *trans*-dibromonitrate is treated similarly to the dibromobromide, except that it is heated over the bare flame. (4) The carbonato-chloride or bromide is treated with conc. hydrobromic acid ($d=1.4$). The bromoaquo-bromide is separated from the less soluble *cis*-dibromo-bromide, which is formed at the same time, by fractional soln. (5) *Cis*-diaquo-bromide is heated at 40° with just enough water to give complete soln. until a violet-coloured soln. is obtained; the bromoaquo-salt is then precipitated with sodium bromide. The dark violet, tabular crystals are readily soluble in water, forming a reddish-violet liquid. A. Gordienko studied the absorption spectrum. A. Werner and R. Schmidt, and A. Uspensky and K. Tschibisoff observed that conc. hydrobromic acid converts the salt into *cis*-dibromobisethylenediamine bromide and a little of the *trans*-salt; whilst conc. hydrochloric acid forms a complex mixture containing *cis*- and *trans*-bromochlorobisethylenediaminechloride, and chlorobisethylenediaminechloride. W. Tupizina prepared **cobaltic bromopyridinebisethylenediaminebromide**, $[\text{Co en}_2\text{prBr}]\text{Br}_2$.

The CoA₄ or Tetrammine Family.

A. Werner and A. Miolati⁸ prepared **cobaltic dibromotetramminobromide**, $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{Br}$, by treating the diaquotetramminobromide with conc. hydrobromic acid; and A. Werner and A. Wolberg, by treating carbonatotetramminobromide with conc. hydrobromic acid, or by the action of hydrobromic acid on a soln. of the corresponding chloride. H. and W. Biltz thus describe the preparation of this salt:

Shake, in a flask, 20 grms. of cobaltic carbonatotetramminonitrate with 80 grms. of conc. hydrochloric acid, and continue shaking while the flask is being slowly heated over

a free flame. Much carbon dioxide is evolved, and the colour changes from a reddish-brown to a pale brown, and, finally, to a dull green. When the colour-change has ceased, let the mixture cool to the temp. of the room, and add 50 c.c. of cold water so as to dissolve a little admixed bromoaquo-bromide. Drain the precipitate on a hardened filter, and wash it with cold water until the filtrate is no longer greyish-brown, but colourless. The yield is 24 grms. of a fine, light yellowish-green, sparingly-soluble powder.

G. and P. Spacu prepared **bismuth cobaltic dichlorobisethylenediaminebromide**, $[\text{Co en}_2\text{Cl}_2]\text{BiBr}_6$; and **stannic cobaltic dichlorobisethylenediaminebromide**, $[\text{Co en}_2\text{Cl}_2]\text{SnBr}_6$.

F. de Boër studied the X-ray absorption spectrum of aq. soln. A. Werner and A. Miolati observed that the dibromotetrammine in aq. soln. rapidly passes into the diaquotetrammine, so that with a soln. of a mol in 500 litres, at 25°, the conductivity rises in 40 mins. from $\mu=190.5$ to 363.5. The final value corresponds with that obtained with the diaquo-bromide. According to A. Werner, and A. Werner and A. Wolberg, when the salt is heated with a little water, it forms hexol-dodecamminobromide; and, according to W. Schramm, oxalic acid forms some oxalatotetramminobromide, but the analogous substitution does not occur with malonic acid. A. Werner and A. Wolberg observed that when the dibromo-amminobromide is triturated with cold, conc. hydrochloric acid, and, after 8 hrs., washed with ice-cold water, and the soln. poured into conc. hydrochloric acid, dark violet, prismatic needles of **cobaltic dibromoamminochloride**, $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{Cl}$, are formed. The salt decomposes at 100°. The green aq. soln. soon changes into a violet soln. of the diaquotetrammine. This salt forms, with auric chloride, pale green, soluble, acicular crystals of **gold cobaltic dibromotetramminotetrachloride**, $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{AuCl}_4$.

A. Werner, E. Schmidt, and W. Tupizina observed that cobaltic *violobromide*, or **cobaltic cis-dibromobisethylenediaminebromide**, $[\text{Co en}_2\text{Br}_2]\text{Br}$, is formed when *cis*- or *trans*-diaquobisethylenediaminebromide is kept for some time; and when bromoaquobisethylenediaminebromide or a sulphitobisethylenediamine salt is treated with hydrobromic acid; and A. Werner and co-workers also found that the *cis*-salt can be obtained by the following processes: (1) A solution of the *trans*-bromide is evaporated on the water-bath several times to a syrupy consistency. On keeping in a vacuum desiccator, black crystals are then obtained, which give a greyish-violet powder; they consist chiefly of the *cis*-isomeride mixed with a little of the *trans*-isomeride. The latter can be extracted with a small quantity of water, leaving the *cis*-form, which can be purified by soln. in water and precipitation with sodium bromide. (2) By fission of diol-quaterethylenediaminebromide with conc. hydrobromic acid into diaquo-bromide and the required dibromo-bromide. The diaquo-salt is removed from the mixture by soln. in absolute alcohol. (3) From carbonatobisethylenediaminebromide by treatment with an alcoholic or aq. soln. of hydrogen bromide by a method similar to that described for the corresponding dichloro-salts. The salt can be purified by precipitation with sodium bromide from its aq. soln. The *cis*-bromide furnishes scaly crystals with a colour and lustre resembling those of graphite. A. Gordienko, and M. L. Ernsberger and W. R. Brode studied the absorption spectrum. K. Matsuno observed that the aq. soln. can be represented by the equations: $[\text{Co en}_2\text{Br}_2]\text{Br} \rightarrow [\text{Co en}_2(\text{H}_2\text{O})\text{Br}]\text{Br}_2 \rightarrow [\text{Co en}_2(\text{H}_2\text{O})_2]\text{Br}_3$. A. Werner found that conc. hydrobromic acid converts the violet *cis*-salt into the green *trans*-salt; and liquid ammonia produces a mixture of *cis*- and *trans*-bisethylenediaminebromide. S. M. Jörgensen prepared **cobaltic praseo-chloride**, or **cobaltic trans-dibromobisethylenediaminebromide**. A. Werner observed that when *cis*- and *trans*-diaquobisethylenediaminebromides are kept for a long time, or when they are heated to 105°; by the action of warm hydrobromic acid on chloroaquobisethylenediaminebromide, or the chloro-bromide, or the sulphato-chloride; and W. Schramm, by the action of malonic acid on *cis*-diaquobisethylenediaminebromide—the yield is small. A. Werner and co-workers also gave these methods of preparation: (a) A soln. of cobalt bromide in 10 per cent. ethylenediamine is oxidized by leading air through it, and then evaporated to dryness. The residue is then repeatedly treated with hydrobromic acid and evaporated until a uniform green salt remains, which consists of the acid bromide. On treatment with a little water, the *trans*-bromide is obtained. (b) Carbonatobisethylenediaminebromide is heated on the water-bath with a soln. of hydrobromic acid, of sp. gr. = 1.49, until the soln. is green. On cooling, the acid bromide separates, from which the normal bromide is best obtained by heating at 110° until it no longer gives an acidic soln. The siskin-green crystals, found by S. M. Jörgensen, have a 4 per cent. solubility in water. A. Gordienko, C. Schleicher, and M. L. Ernsberger and W. R. Brode, studied the absorption spectrum. S. M. Jörgensen observed that the aq. soln. becomes dark red when boiled, owing to the formation of the aquo-salt;

A. Werner said that *cis*-bromoquo-bromide is formed; conc. aq. ammonia converts the salt into *cis*-bromobisethylenediamineamminobromide, and liquid ammonia produces *cis*-bisethylenediaminediamminobromide with a little of the trans-salt. According to S. M. Jörgensen, 1:1-hydrochloric acid gives no precipitate, but crystalline precipitates are produced in a 4 per cent. soln. by the addition of dil. nitric acid, sodium dithionate or bromoplatinate, and by potassium iodide, bromomercurate, or ferricyanide—potassium ferrocyanide colours the soln. red. W. Schramm found that oxalic acid forms the oxalato-bromide, whilst malonic acid gives a mixture of violet bromoquo-bisethylenediaminebromide, and green dibromobisethylenediaminebromide. H. Seibt prepared **cobaltic difluorobisethylenediaminebromide**, $[\text{Co en}_2\text{F}_2]\text{Br}$. S. M. Jörgensen, and A. Werner obtained crystals of **cobaltic dibromobisethylenediaminebromide**, $[\text{Co en}_2\text{Br}_2]\text{Br} \cdot 2\text{H}_2\text{O}$; according to H. Grossmann and B. Schück, the salt is a monohydrate, of m.p. 214° . The constitution was discussed by A. Werner, and T. S. Price and S. A. Brazier. S. M. Jörgensen, and T. S. Price and J. C. Duff noted the formation of **mercuric cobaltic dibromobisethylenediaminebromide**, $[\text{Co en}_2\text{Br}_2]\text{Br} \cdot \text{HgBr}_2$. A. Werner and A. Grün treated a conc. aq. soln. of cobaltic bromochloroquoethylenediamineamminobromide with its own vol. of hydrobromic acid, and obtained green, stellar aggregates of crystals of cobaltic **dibromoquoethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)\text{en}(\text{H}_2\text{O})\text{Br}_2]\text{Br}$, which are dichroic—bluish-black, and brown. G. Lindenberg prepared **cobaltic dibromobisethylenediaminebromide**, $[\text{Co tr}_2\text{Br}_2]\text{Br}$.

A. Werner and A. Grün reported **cobaltic dibromoquoethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)\text{en}(\text{H}_2\text{O})\text{Br}_2]\text{Br}$, by warming bromochloroquoethylenediamineamminobromide with water, and then an equal vol. of hydrobromic acid of sp. gr. 1.49. The small, stellate aggregates of needles are strongly dichroic from bluish-black to brown, and when powdered, the salt is green. It forms a brown soln. with water.

A. Werner prepared **cobaltic cis-dichlorotetramminobromide**, $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Br}$, by the action of an aq. soln. of ammonium bromide on the corresponding dithionate, and precipitation from the aq. soln. by ammonium bromide. The violet-blue crystals are sparingly soluble in water, and the blue, aq. soln. rapidly changes to violet because of the formation of the aquo-salt. S. M. Jörgensen, and A. Werner and A. Klein also obtained **cobaltic trans-dichlorotetramminobromide** by adding hydrobromic acid to an aq. soln. of the sulphate. The green, rhombic crystals were found by F. Ephraim and O. Schütz to have a sp. gr. of 2.143 at 25° , a mol. vol. of 129.7, and a vol. contraction of 59.6 per cent. in the formation of the salt. When heated at 100° for 24 hrs., it loses 2 per cent., and in 6 weeks, 25 per cent. in weight. A. N. Nikolopulos, and R. Luther and A. N. Nikolopulos studied the absorption spectrum. A. Werner and A. Miolati found that the mol. conductivity of a soln. of a mol. of the salt in 512 litres of water at 25° , changes in 40 mins. from $\mu=116.6$ to 332.1, as the green soln. passes to a violet-red soln. of the aquo-salt. The aquation was studied by L. Tschugaeff. J. N. Brønsted and co-workers found that a sat. aq. soln. at 0° contains 0.00632 mol per litre, and they studied the effect produced by the presence of different salts. A. Werner said that silver nitrate precipitates from the soln. what is probably a double salt.

A. Werner and R. Feenstra reported **cobaltic trans-dichloroquaterpyridinobromide**, $[\text{Co py}_4\text{Cl}_2]\text{Br}$, to be formed by the action of potassium bromide on a soln. of the corresponding chloride. The pale blue crystals can be freed from water only by long-continued drying in the desiccator. P. Larisch prepared **cobaltic dichlorobisethylenediaminebromide**, $[\text{Co en}_2\text{Cl}_2]\text{Br} \cdot \text{H}_2\text{O}$, in violet crystals, by the action of solid potassium bromide on a cold, sat. soln. of the corresponding chloride; 100 c.c. of water at 1° dissolve 0.878 grm. of the salt. A. Werner, and A. Werner and G. Tschernoff obtained the *dextro*-salt and the *laevo*-salt, in indigo-blue crystals, by adding alcohol to a soln. of the camphor bromosulphonates in hydrobromic acid. The sp. rotation of a 0.25 per cent. soln. is $[\alpha]=168^\circ$ for the *dextro*-salt, and $[\alpha]=-176^\circ$ for the *laevo*-salt. S. M. Jörgensen obtained **cobaltic trans-dichlorobisethylenediaminebromide**, as a matte green powder by treating the corresponding chloride with hydrobromic acid. E. Petersen measured the lowering of the f.p., and the mol. conductivity of the soln. at 0° and 25° , and inferred that at 0° the salt is stable in aq. soln. The subject was discussed by A. Werner and C. Herty, and W. D. Harkins and co-workers. G. and P. Spacu prepared the double salt: **cadmium cobaltic dichlorobisethylenediaminebromide**, $[\text{Co en}_2\text{Cl}_2]_2\text{CdBr}_4$. A. Werner and A. Fröhlich, and H. E. Watts prepared **cobaltic trans-dichlorobispropyldiaminebromide**, $[\text{Co pn}_2\text{Cl}_2]\text{Br} \cdot \text{H}_2\text{O}$, by the action of potassium bromide on the corresponding chloride. The matte green, crystalline powder is very soluble in water, but cannot be re-crystallized from aq. soln. A. Werner and F. Chaussy obtained **cobaltic cis-dichloroethylenediaminediamminobromide**, $[\text{Co}(\text{NH}_3)_2\text{enCl}_2]\text{Br}$, as a violet-blue precipitate, by treating carbonatoethylenediamine-diamminochloride with very conc. hydrochloric acid at -16° , when the development of

carbon dioxide has ceased, adding ammonium bromide; **cobaltic trans-dichloroethylenediaminediamminobromide**, was likewise formed as a green precipitate, by the action of hydrobromic acid or ammonium bromide on a conc., aq. soln. of the chloride at 0°.

A. Werner prepared **cobaltic cis-hydroxychlorobisethylenediaminebromide**, $[\text{Co en}_2(\text{OH})\text{Cl}]\text{Br}$, in brownish-violet crystals, by adding conc. ammonia to chloroaquobisethylenediaminebromide. In warm aq. soln., aquation occurs, and the cis-hydroxyaquo-bromide is formed, and with hot, conc. hydrochloric acid, cis-dichloro-chloride, accompanied by a small proportion of trans-dichlorochloride, is formed. The *dextro-salt* and the *levo-salt*, as monohydrates, were prepared by H. Fischlin from the corresponding chloroaquobromides by treatment first with conc. ammonia, and then with 1 : 1-alcohol. After washing with a little conc., aq. ammonia, the brownish-violet crystals are dried by alcohol and ether. The sp. rotation of a 0.1 per cent. aq. soln. of the *dextro-salt* is $[\alpha] = 695^\circ$, and of the *levo-salt*, -687° .

A. Werner reported **cobaltic hydroxybromobisethylenediaminebromide**, $[\text{Co en}_2(\text{OH})\text{Br}]\text{Br}$, to be formed as a brownish-violet salt by treating bromoaquobisethylenediaminebromide with conc. ammonia. When the salt is warmed with a little water, aquation occurs and the cis-hydroxyaquo-bromide is formed; and when triturated with conc. hydrobromic acid, the cis-diaquo-bromide is produced. A. Gordienko studied the absorption spectra of aq. soln. A. Werner also prepared, in a similar manner, **cobaltic hydroxy-chlorobisethylenediaminebromide**, $[\text{Co en}_2(\text{OH})\text{Cl}]\text{Br}$, as a brownish-violet mush of crystals, by treating chloroaquobisethylenediaminebromide with conc. ammonia. With hot, conc. hydrochloric acid, it forms cis-dichloro-chloride accompanied by a small proportion of trans-dichloro-chloride.

A. Werner and A. Grün prepared **cobaltic bromochloroaquotriamminobromide**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{ClBr}]\text{Br}$, by the action of fuming hydrobromic acid on the chlorodiquotriamminosulphate. The olive-green crystals furnish a green soln. which quickly turns blue. If an aq. soln. of blue chlorodiquotriamminobromide is treated with hydrobromic acid, or if conc. hydrobromic acid is added to an aq. soln. of dichloroaquotriamminochloride, chocolate-brown crystals of the *monohydrate* are formed. The soln. in water is green at 0°, bluish-violet at ordinary temp., and red at higher temp. The crystals lose a mol. of water at 100°. Potassium iodide precipitates the brown iodide from the cold, aq. soln., and conc. nitric acid, the green nitrate.

A. Werner, and A. Werner and G. Tschernoff prepared **cobaltic bromochlorobisethylenediaminebromide**, $[\text{Co en}_2\text{ClBr}]\text{Br} \cdot \text{H}_2\text{O}$, by covering 2 grms. of chlorobisethylenediaminebromide with 2 c.c. of conc. hydrobromic acid, and the mixture heated until complete soln. takes place. On cooling, a mixture of the green and violet salt is obtained, which is washed with alcohol and ether, dried, and then treated with a small quantity of water to dissolve out the green salt. The violet salt (cis-isomeride) is collected, washed with water and alcohol, and dried. The green filtrate gives precipitates with metallic salts, which give analytical results corresponding with a mixture of dibromo- and chlorobromo-salts. The salt is also formed when chloroaquobisethylenediaminebromide is heated for 2 hours at 110°, whereby a mixture of the cis- and trans-chlorobromo-bromides is produced. This is separated as before. The *dextro-salt*, and the *levo-salt* are derived from the corresponding camphor bromosulphonates, in dark greyish-violet, crystalline powders, which lose a mol. of water at 110°. The sp. rotation of the *dextro-salt* is $[\alpha] = 148^\circ$, and of the *levo-salt*, -155° . M. L. Ernsberger and W. R. Brode studied the absorption spectrum. The corresponding **cobaltic bromochlorobisethylenediaminechloride**, $[\text{Co en}_2\text{ClBr}]\text{Cl} \cdot \text{H}_2\text{O}$, was prepared in an analogous manner as dark greyish-violet crystalline powder. The sp. rotation of the *dextro-salt* is $[\alpha] = 164^\circ$, and of the *levo-salt*, -176° . If a conc. soln. of dichloroaquoethylenediamineamminochloride is treated with hydrobromic acid, **cobaltic bromochloroaquoethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})\text{ClBr}]\text{Br}$, is formed in olive-green crystals. Conc. nitric acid converts it into the nitrate, and potassium iodide, into the iodide of the series.

The CoA_3 or Triammine Family.

E. Birk⁹ prepared **cobaltic tribromotriammine**, $[\text{Co}(\text{NH}_3)_3\text{Br}_3]$, by treating triol-hexamminobromide with conc. hydrobromic acid.

Complexes with Two or More Cobalt Atoms.

A. Werner¹⁰ prepared **cobaltic μ -amino-decamminobromide**, $[(\text{NH}_3)_5\text{Co} - \text{NH}_2 \cdots \text{Co}(\text{NH}_3)_5]\text{Br}_5 \cdot \text{H}_2\text{O}$, by the action of ammonium bromide on the nitrate, sulphate, or dithionate. The reddish-brown needles form a 0.5 per cent. soln.

with water at room temp. Ammonium bromide precipitates the salt almost quantitatively from its aq. soln. The salt loses water at 80° to 85° without decomposition, but with warm, conc. sulphuric or nitric acid, the hexammino- and chloropentammino-salts are formed.

A. Werner, and A. Baselli, prepared **cobaltic bromoaquo- μ -amino-octamminobromide**, $[(\text{H}_2\text{O})(\text{NH}_3)_4\text{Co}-\text{NH}_2\cdots\text{Co}(\text{NH}_3)_4\text{Br}]\text{Br}_4$, by the action of conc. hydrobromic acid on μ -amino-ol-octamminosulphate. The dark brown, acicular crystals dissolve in water, and the reddish-brown soln. has an acidic reaction; the aq. soln. soon becomes carmine-red owing to the formation of μ -amino-ol-octamminobromide.

A. Werner and F. M. Grigorieff, and I. Fürstenberg obtained **cobaltic tetrabromo- μ -amino-hexamminobromide**, $[\text{Br}_2(\text{NH}_3)_3\text{Co}-\text{NH}_2\cdots\text{Co}(\text{NH}_3)_3\text{Br}_2]\text{Br}\cdot 2\text{H}_2\text{O}$, by warming an aq. soln. of μ -amino-diol-hexamminobromide with conc. hydrobromic acid on the water-bath. The salt is also prepared by reducing μ -amino-peroxo-ol-hexamminobromide with sulphurous acid, and the addition of conc. hydrobromic acid to the resulting soln. gives greenish-black crystals. The greenish-brown, crystalline powder loses 2 mols. of water at 70° to 80°; it is insoluble in cold water; an acidified soln. of silver nitrate, μ -amino-diol-hexamminonitrate or diaquo- μ -amino-ol-hexamminonitrate is formed in aq. soln.

A. Werner prepared **cobaltic diol-octamminobromide**, $[(\text{NH}_3)_4\text{Co}\cdots(\text{OH})_2\cdots\text{Co}(\text{NH}_3)_4]\text{Br}_4\cdot 4\text{H}_2\text{O}$, by treating the corresponding chlorides with a sat. soln. of potassium bromide. The ruby-red crystals are freely soluble in water, and potassium bromide precipitates the salt from its aq. soln. Two mols. of water are lost over sulphuric acid; and all is given off at 80°. Observations on the salt were made by H. Frank; L. C. Jackson studied the magnetic properties; and E. Rosenbohm gave -1.19×10^{-7} mass unit for the magnetic susceptibility.

A. Werner and J. Rapport prepared **cobaltic diol-quaterethylenediaminebromide**, $[\text{en}_2\text{Co}\cdots(\text{OH})_2\cdots\text{Co en}_2]\text{Br}_4\cdot 4\text{H}_2\text{O}$. The action of conc. hydrochloric acid on hexol-sexiesethylenediaminenitrate, furnishes crystals of cis-diaquobis-ethylenediaminechloride, and, when this product is digested with pyridine and sodium dithionate, it yields crystals of cis-hydroxyaquobisethylenediaminedithionate. This salt at 100° to 110° loses water, to form the dithionate of the required salt. When the dithionate is triturated with ammonium bromide and water, it yields reddish-violet needles of the *tetrahydrate*, which loses two mols. of water at 100°, or over conc. sulphuric acid, forming the *dihydrate*. The preparation of the salt was also described by H. Frank, and by J. V. Dubskey. L. C. Jackson studied the magnetic properties; and E. Rosenbohm found the magnetic susceptibility to be -2.64×10^{-7} mass unit. A. Werner and J. Rapport found that at 12°, fuming hydrobromic acid converts the salt into cis-dibromobis-ethylenediaminebromide.

A. Werner prepared **cobaltic μ -diamino-octamminobromide**, $[(\text{NH}_3)_4\text{Co}\cdots(\text{NH}_2)_2\cdots\text{Co}(\text{NH}_3)_4]\text{Br}_4\cdot 4\text{H}_2\text{O}$. He said that in the preparation of cis-dichlorotetramminochloride from diol-octamminochloride, the crude substance sometimes assumes a superficial red colour when dried over phosphorus pentoxide. If this partly-changed product is dissolved in water, and sodium dithionate added after half an hour, orange-yellow crystals of μ -diamino-octamminodithionate are precipitated, and on triturating the precipitate with a little water and ammonium bromide, red crystals of the *tetrahydrate* are formed.

A. Werner obtained **cobaltic hydroxyaquo-peroxo-ol-hexamminobromide**, $[(\text{OH})(\text{NH}_3)_3\text{Co}=(\text{OH})\text{O}_2\cdots\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})]\text{Br}_3$, by rubbing up the sulphate with ammonium bromide and a little water. The greenish-brown needles form, with water, a brown soln. having a feebly acidic reaction. The solid becomes red on keeping.

A. Werner,¹¹ prepared **cobaltic μ -ammonium-peroxo-quaterethylenediaminebromide**, $[\text{en}_2\text{Co}=\text{O}_2(\text{HN.HBr}_3)=\text{Co en}_2]\text{Br}_3\cdot 3\text{H}_2\text{O}$, by treating a soln. of the corresponding nitrate with potassium bromide; red crystals of the *trihydrate* are formed. The crystals dissolve in water, which is turned red, and then green by mineral

acids. A *monohydrate* can also be obtained. A. Werner and co-workers obtained the anhydrous *dextro-salt*, and *laevo-salt* by treating an ice-cold soln. of the μ -amino-peroxy-quaterethylenediaminebromide with hydrobromic acid. The impure, reddish-brown crystalline powder can be purified by converting it into the dithionate and rubbing up the product with sodium bromide and water, washing the pale red, crystalline powder with alcohol and ether, and drying it over calcium chloride. The sp. rotation of a 0.125 per cent. soln. of the *dextro-salt* is $[\alpha] = 208^\circ$.

A. Werner and R. Feenstra obtained compounds which appeared to contain an imino-group, but, according to A. Werner, the question is an open one. By treating iminobispyridineoctamminotetrachloride with conc. hydrobromic acid, **cobaltic iminobispyridine-octamminotetrabromide**, $[(\text{NH}_3)_4\text{py}.\text{Co}.\text{NH}.\text{Co}(\text{NH}_4)\text{py}]\text{Cl}_4$, was found in brown, acicular crystals; and by treating a soln. of diaquo- μ -amino-ol-hexamminonitrate with hydrobromic acid, A. Werner and F. Steinitzer obtained a dirty green powder of **cobaltic iminohexamminobromide**, $\text{Co}(\text{NH}_3)_6(\text{NH})\text{Br}_4$, but its nature has not yet been established.

There is also the black, crystalline powder, **cobaltic diozo-trimidodexamminobromide**, $(\text{O}_2)_2(\text{NH})_3\text{Co}_4(\text{NH}_3)_{16}\text{Br}_8.\text{H}_2\text{O}$, prepared by A. Werner and co-workers by the action of hydrobromic acid on the nitrate. Its constitution has not been established.

A. Werner and F. Beddow,¹² and A. Werner and A. Grün obtained **cobaltic μ -amino-peroxy-octamminobromide**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)\text{O}_2\cdots\text{Co}(\text{NH}_3)_4]\text{Br}_4.\text{H}_2\text{O}$, by triturating G. Vortmann's sulphate—*vide supra*, the corresponding chloride—with conc. hydrobromic acid; or by similarly treating the sulphate of the series. The microcrystalline powder consists of green prisms. The aq. soln. of the salt decomposes rapidly.

A. Werner and co-workers¹³ prepared **cobaltic μ -amino-peroxy-quaterethylenediaminebromide**, $[\text{en}_2\text{Co}=(\text{NH}_2)\text{O}_2\cdots\text{Co en}_2]\text{Br}_4.6\text{H}_2\text{O}$, by treating a cold, sat. soln. of the corresponding nitrate with ammonium bromide. The cubic crystals of the *hexahydrate* appear almost black in reflected light, and yellowish-green in transmitted light. The salt becomes anhydrous at 110° . The aq. soln. is yellowish-green, and it has a neutral reaction. J. Angerstein, and A. Gordienko studied the absorption spectra of aq. soln. The *dextro-salt*, and the *laevo-salt* can be obtained from the corresponding camphor bromosulphonates. The greenish-black, prismatic crystals, in 0.125 per cent. aq. soln., have the sp. rotations $[\alpha] = 840^\circ$ for *dextro-salt*, and -840° for the *laevo-salt*.

A. Werner¹⁴ prepared **cobaltic dibromo- μ -amino-peroxy-hexamminobromide**, in *symmetrical* and *asymmetrical* forms:

Symmetrical form

Asymmetrical form

The symmetrical variety was obtained by the action of conc. hydrobromic acid on a warm, aq. soln. of μ -amino-peroxy-ol-hexamminobromide; the small, greenish-black crystals are sparingly soluble in water. The asymmetrical form was prepared by the action of ammonium bromide on the asymmetrical chloride. The dark brown crystals are easily soluble in water, and pass into μ -amino-peroxy-octamminobromide when treated with liquid ammonia. A. Werner and A. Baselli¹⁵ found that **cobaltic μ -amino-ol-octamminobromide**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{OH})\cdots\text{Co}(\text{NH}_4)_4]\text{Br}_4.4\text{H}_2\text{O}$, separates out when an aq. soln. of bromoaquo- μ -amino-octamminobromide is allowed to stand for some time, and the same salt is produced when the sulphate is rubbed up with conc. hydrobromic acid, and the product crystallized from water acidulated with acetic acid. The garnet-red, prismatic crystals of the *tetrahydrate* effloresce over sulphuric acid; at 60° , and over phosphorus pentoxide, all 4 mols. of water are given off. Water dissolves about 1.3 per cent. of the salt; and conc. hydrobromic acid converts it into bromoaquo- μ -amino-octamminobromide. A. Werner prepared dark red crystals of **cobaltic μ -amino-ol-quaterethylenediaminebromide**, $[\text{en}_2\text{Co}=(\text{NH}_2)(\text{OH})\cdots\text{Co en}_2]\text{Br}_4.4\text{H}_2\text{O}$, in dark red crystals, by triturating the iodide with ammonium bromide.

A. Werner¹⁶ prepared **cobaltic triol-hexamminobromide**, $[(\text{NH}_3)_3\text{Co}\cdots(\text{OH})_3]$

$\text{Co}(\text{NH}_3)_3\text{Br}_3$, by warming 10 grms. of bromochloroaquotriamminobromide with 50 c.c. of water for a few minutes at 60° . The salt forms red, acicular prisms. The sat., aq. soln. has 7.7 per cent. of the salt at room temp. The aq. soln. is decomposed by heat. G. R. Mines studied the physiological action.

A. Werner, and I. Fürstenberg obtained **cobaltic μ -amino-diol-hexamminobromide**, $[(\text{NH}_3)_3\text{Co}(\text{NH}_2)(\text{OH})_2]_3\text{Co}(\text{NH}_3)_3\text{Br}_3$, by treating a warm soln. of diaquo- μ -amino-ol-hexamminonitrate with ammonium bromide; or by triturating the corresponding iodide with silver bromide. The small, needle-like crystals are sparingly soluble in cold water, and the aq. soln. has a neutral reaction. A. Werner, and A. Werner and F. M. Grigorieff prepared cobaltic- μ -amino-peroxo-ol-hexammine, and A. Werner and F. M. Grigorieff prepared **cobaltic μ -amino-peroxo-ol-hexamminobromide**, $[(\text{NH}_3)_3\text{Co}(\text{NH}_2)(\text{OH})_2]_3\text{Co}(\text{NH}_3)_3\text{Br}_3 \cdot 2\text{H}_2\text{O}$ —*vide supra*, the corresponding chloride. The black chloride is triturated with a conc. soln. of silver nitrate, and when the filtrate is saturated with ammonium bromide, dark green crystals of the *dihydrate* are formed. The aq. soln. has a neutral reaction. The salt is reduced by sulphurous acid to a μ -amino-diol-hexammino-salt.

A. Werner¹⁷ prepared **cobaltic hexol-hexamminobromide**, $[(\text{NH}_3)_3\text{Co}(\text{OH})_3]_3\text{Co}(\text{NH}_3)_3\text{Br}_3$, by treating 2 grms. of the corresponding chloride with 1 c.c. of conc., aq. ammonia, and 80 c.c. of water, and adding ammonium bromide to the rapidly-filtered liquid. The small, brown, scaly crystals are washed with alcohol and ether.

A. Werner¹⁸ obtained **cobaltic hexol-dodecamminobromide**, $[\text{Co}(\text{OH})_2 = \text{Co}(\text{NH}_3)_4]_3\text{Br}_6 \cdot 8\text{H}_2\text{O}$, by heating dibromotetramminobromide with a little water, and filtering rapidly, when the soln., almost black, deposits black, tabular crystals. It is also obtained by precipitation from a soln. of another salt of the series by means of sodium bromide. It can be re-crystallized from conc. acetic acid, and washed with alcohol and ether. When air-dried, the product is the *octohydrate*. A. Werner also prepared the *dextro-salt*, and the *laevo-salt* by adding sufficient silver camphorbromosulphonate to precipitate all the chlorine, and then treating the soln. with dil. acetic acid. The first crops of crystals of the *d*-camphorbromosulphonate are usually *laevo*-rotatory, and those of the *l*-camphorbromosulphonate, *dextro*-rotatory. The active bromides were prepared by dissolving these salts in just sufficient aq. acetone (50 per cent.), adding small quantities of sodium bromide until the precipitate had a marked activity, and then diluting the mother-liquor with absolute alcohol. The *dextro*- and *laevo*-bromides crystallized as *dihydrates*. The 0.05 per cent. soln. in 1:1 aqueous acetone, and $\lambda = 560$, had the sp. rotations $[\alpha] = 1050^\circ$ for the *dextro-salt*, and -4500° for the *laevo-salt*. The anomalous dispersion was studied by A. Werner, and J. Lifschitz. A. Werner prepared **cobaltic hexol-sexiesethylenediamineobromide**, $[\text{Co}(\text{OH})_2 = \text{Co}(\text{en})_2]_3\text{Br}_6$, by treating a conc. soln. of the nitrate with sodium bromide. The reddish-brown, acicular crystals are freely soluble in water. Cobaltic hydroxide separates from the boiling, aq. soln.; hydrobromic acid converts it into green trans-dibromobisethylenediaminebromide.

§ 20. Cobaltous Iodide

O. L. Erdmann¹ obtained **cobaltous iodide**, CoI_2 , by heating powdered cobalt and iodine in a glass tube, and added that the resulting product is greyish-green, without metallic lustre, and fuses when heated, but does not sublime. It is also obtained by heating cobalt in a current of iodine vapour. W. Biltz and E. Birk obtained the iodide by heating spongy cobalt—obtained by heating the oxalate in hydrogen—in a current of hydrogen iodide below the m.p. of cobalt iodide, 400° to 500° , then raising the temp. to about 550° , when the iodide melts, and finally cooling in vacuo, so as to remove the absorbed gases. W. N. Hartley, and A. Étard dehydrated the hexahydrate by keeping it in a vacuum over conc. sulphuric acid for 5 or 6 days; W. N. Hartley, by heating the hexahydrate to 130° ; and A. Ferrari and F. Giorgi, by drying and melting the hexahydrate in a current of hydrogen and hydrogen iodide. C. F. Rammelsberg, and O. L. Erdmann obtained an aq. soln. of the salt by placing the finely-divided metal in contact with iodine and water, when the temp. rises and a red liquid is formed. I. Bolschakoff observed that if the aq. soln. be evaporated and then cooled, crystals of the *hexahydrate*, $\text{CoI}_2 \cdot 6\text{H}_2\text{O}$, are formed as red, hexagonal prisms—W. N. Hartley recommended cooling the liquid to about 16° ; a further concentration and cooling of the soln., by a freezing mixture, yields the *enneahydrate*, $\text{CoI}_2 \cdot 9\text{H}_2\text{O}$, which forms red, rhombic plates; and these crystals, at 6.4° , form the hexahydrate. A. Étard obtained the *tetrahydrate*, $\text{CoI}_2 \cdot 4\text{H}_2\text{O}$, in green plates from hot, conc. soln.; and W. N. Hartley, and C. F. Rammelsberg obtained the green *dihydrate*, $\text{CoI}_2 \cdot 2\text{H}_2\text{O}$, by evaporating a conc. soln. of the salt over sulphuric acid.

According to W. Biltz and E. Birk, the vapour of ordinary cobalt iodide in vacuo, partly condenses as iodine, and partly as an ochre-yellow sublimate of unstable **β -cobalt iodide**; the ordinary black, stable form is **α -cobalt iodide**. The sp. gr. of the β -iodide is 5.45 at $25^\circ/4^\circ$, being rather less than that of the α -iodide. When the yellow β -iodide is heated to 400° , it forms the black α -iodide. The α -iodide forms a rose-red soln. when dissolved in water, but the aq. soln. of the β -iodide is pale wine-yellow, and the soln. is almost colourless if free iodine has been removed by chloroform. The aq. soln. of the β -iodide is stable for about a day, and with warming or concentration in vacuo, it becomes rose-red. Both the rose-red and the pale yellow soln. have the same electrical conductivities.

Ordinary cobalt iodide, α -iodide, is black; and, according to A. Hantzsch, the

greenish colour which it usually appears to have, is due to the presence of a little free iodine. The crystals are hexagonal, and A. Ferrari and F. Giorgi observed that the space-lattice is of the cadmium iodide type, with $a=3.96$ A., $c=6.65$ A., and $a:c=1:1.68$. W. Biltz and E. Birk gave 5.584 for the sp. gr. at $25^\circ/4^\circ$; and G. L. Clark and H. K. Buckner gave 5.68—A. Ferrari and F. Giorgi calculated 5.75 from the X-radiograms. W. Biltz and E. Birk gave 56.02 for the mol. vol., and the subject was discussed by F. Ephraim, and F. Ephraim and O. Schütz. G. L. Clark and H. K. Buckner gave 2.90 for the sp. gr. of the hexahydrate, and said that there is an 11.2 per cent. contraction in the reaction: $\text{CoI}_2 + 6\text{H}_2\text{O} = \text{CoI}_2 \cdot 6\text{H}_2\text{O}$. G. Devoto and A. Guzzi gave 495° for the m.p., but W. Biltz and E. Birk gave 515° to 520° in vacuo, and A. Ferrari and F. Giorgi, 515° in a current of iodine. I. Bolschakoff found the enneahydrate passes into the hexahydrate at 6.4° ; W. N. Hartley said that the hexahydrate loses its water slowly in vacuo over sulphuric acid, or rapidly at 130° . The iodide begins to lose iodine at about 540° , and it boils at 570° to 575° with the dissociation of part of the iodide into iodine and cobalt. Some β -iodide is formed as a sublimate. K. Jellinek and R. Ulroth found the partial press. of the iodine at 535° , 605° , and 685° to be, respectively, $P_{\text{I}_2}=1.91 \times 10^{-3}$, 6.76×10^{-3} , and 2.57×10^{-2} . W. Geller measured the vap. press. of aq. soln. G. Devoto and A. Guzzi gave for the heat of formation from gaseous iodine $(\text{Co}, \text{I}_2)=39.13$ Cals.; W. Biltz, $(\text{Co}, \text{I}_2, \text{Aq.})=57$ Cals.; and M. Berthelot, and L. Pigeon, 54.3 Cals. With iodine in soln., J. Thomsen gave $(\text{Co}, \text{I}_2, \text{Aq.})=42.52$ Cals.; L. Pigeon, 41.5 Cals.; and M. Berthelot, 40.7 Cals. G. Devoto and A. Guzzi gave 18 Cals. for the heat of soln. of a mol of the anhydrous iodide in 1900 mols of water at 18° ; and A. Mosnier, 18.8 Cals. F. Ephraim and O. Schütz, and E. Rabinowitsch and E. Thilo discussed the heats of formation of the halides of the cobalt family. G. Devoto and A. Guzzi calculated for the free energy of formation of the molten salt, 13,800 cal.

H. Fesefeldt measured the absorption spectrum of thin films of the iodide. A. Étard observed that between -22° and 20° , the aq. soln. is dark red; at higher temp., it becomes olive-green; and above 35° , green. Observations on the colour and absorption spectrum were made by W. Ackroyd, W. R. Brode and R. A. Morton, W. R. Brode, F. L. Cooper, G. Denigès, and R. A. Houstoun and co-workers.

W. Riedel found the electrical conductivity of soln. with a mol of the iodide, in v litres, at 25° :

v	20°	80°	320°	1280°	5120°
μ	99.02	109.03	116.15	121.50	127.93
α	0.77	0.85	0.90	0.94	0.995

The limiting value at infinite dilution is 128.61. The calculated degrees of ionization, α , are indicated above; the transport numbers for the anion for $v=20.8$, 203.5, and 432, at 18° , are, respectively, 0.6218, 0.6062, and 0.6040; and for the cations, 0.3782, 0.3938, and 0.3960. The degrees of the hydrolysis for soln. with 0.05 and 0.01 mol per litre, are, respectively, 0.05 and 0.11 per cent., and the H^+ -ion concentration, respectively, $10^{-4.90}$, and $10^{-4.95}$. G. Dickhaus gave for a soln. of 0.0458 grm. of CoI_2 in 100 c.c. of water, at different temp:

	33°	34°	37°	38°	46°	47°
Conductivity	184.935	181.475	172.406	169.168	148.460	145.973

There are irregularities between 33.6° and 33.7° , between 37.7° and 37.8° , and between 46.2° and 46.3° ; irregularities were also observed by J. Hamacher between 24° and 25° , between 39° and 41° , between 35° and 39° , and between 40° and 42° . P. Walden measured the conductivity of soln. of the salt in phosphoryl chloride. G. Devoto and A. Guzzi found the decomposition potential of the molten iodide is 0.872 volt at 700° , 0.802 volt at 750° , 0.704 volt at 800° , and 0.590 volt at 850° . W. Riedel gave for the e.m.f. of the cell $\text{Pt}(\text{H}_2) | \text{CoI}_2 | \text{KCl}_{\text{sat. soln.}} | 0.1\text{N-KCl}, \text{Hg}_2\text{Cl}_2 | \text{Hg}$, with the cobalt iodide soln. containing 0.05 and 0.01 mol. per litre, respectively, 0.6270 and

0.630 volt. G. Tammann and H. O. von Samson-Himmelsjerna studied the potential of cobalt in soln. of the iodide. W. Klemm and W. Schüth found the magnetic susceptibilities at 91° K., 195° K., 293° K., 513° K., and 673° K. to be, respectively, $\chi \times 10^6 = 100, 51.4, 34.4, 19.4$, and 14.6 . O. Liebknecht and A. P. Wills found the magnetic susceptibility of an aq. soln. to be 33×10^{-6} mass unit at 18°.

Cobalt iodide is reduced to the metal when heated in hydrogen. K. Jellinek and R. Ulroth found that in the balanced reaction: $\text{CoI}_2 + \text{H}_2 \rightleftharpoons \text{Co} + 2\text{HI}$, the equilibrium constant, $P_{\text{HI}}^2/P_{\text{H}_2}$, is 0.30, 0.57, and 1.21, respectively, at 535°, 605°, and 685°. According to A. Étard, the percentage solubility, S , of the salt in water, is:

	-22°	-8°	-2°	9°	25°	46°	82°	111°	156°
S	52.4	56.7	58.7	61.4	66.4	79.0	80.7	80.9	83.1

A. Étard supposed the solid phase for the rose-red soln. below 20° to contain the hexahydrate; the mixed colour, olive-green between 20° and 35°, represented a mixture of the hexahydrate and the tetrahydrate; and the green colour above 35°, the tetrahydrate; and he found the solid phase above 46° to be the dihydrate. According to I. Bolschakoff, the transition temp. for the ennea- and hexahydrates is 6.4°; and for the hexa- and tetrahydrates, 27°. C. F. Rammelsberg observed that cobalt iodide dissolves in a small proportion of water, forming a green soln., and with a larger proportion of water, a red soln. W. N. Hartley added that when the salt is dissolved in the smallest possible proportion of water, the soln. is red at -10°, and with a rising temp. the liquid passes through all shades of colour, from brown to olive-green, at 75°. The subject was discussed by J. H. Gladstone, and W. Ackroyd—*vide supra*, cobaltous chloride. W. N. Hartley observed that the hydrate, at 100°, loses nearly all its water, to form **cobalt oxyiodide**, CoOI_3 , and C. F. Rammelsberg obtained what he regarded as a basic salt. By adding ammonia to a dil. soln. of cobalt iodide, a brown liquid is formed—presumably the peptized hydroxide—and a blue precipitate is produced which turns green when washed and dried. W. Riedel observed that cobaltous iodide unites with iodine to form a **cobaltous polyiodide**, possibly CoI_4 , in aq. soln.; the conductivities corresponding with soln. containing a mol of the salt in v litres, at 25°, and the degrees of ionization, α , are:

v	20	80	320	1280	5120	∞
μ	85.45	94.16	102.92	110.33	114.98	114.39
α	0.745	0.821	0.899	0.962	1.000	—

R. F. Weinland and F. Schlegelmilch found that when a sat. soln. of cobaltous chloride is treated with iodine, dark orange-red crystals of **cobalt chloriodide**, $\text{CoCl}_2 \cdot \text{ICl}_3 \cdot 8\text{H}_2\text{O}$, are formed. The iodine chloride can be extracted with carbon tetrachloride. P. Walden observed that the iodide forms a violet soln. with thionyl chloride; and a yellowish-brown soln. with selenium monochloride. C. Dufraisse and D. Nakae studied the catalytic oxidation of sodium sulphite soln.; and A. Hantzsch and H. Carlsohn, the action of dil. sulphuric acid on the salt.

C. F. Rammelsberg found that when dry cobalt iodide is heated in dry ammonia, it swells up to form a red powder, **cobaltous hexamminoiodide**, $\text{CoI}_2 \cdot 6\text{NH}_3$, or $[\text{Co}(\text{NH}_3)_6]\text{I}_2$. W. Biltz could not obtain *cobalt decamminoiodide* analogous with the decammino-chloride. C. F. Rammelsberg also described *cobaltous tetramminoiodide*, $\text{CoI}_2 \cdot 4\text{NH}_3$, said to be formed, in rose-red crystals, by cooling the violet liquid obtained by adding an excess of ammonia to a warm conc. soln. of cobalt iodide. W. Biltz and B. Fetkenheuer found that the product is the hexammine, not the tetrammine, and they modified the process by treating a hot, conc. soln. of cobalt iodide with conc. aq. ammonia until the precipitate which is first formed passes into soln., then adding air-free alcohol until a slight turbidity appears, cooling the soln., and washing the precipitate with conc. ammonia, and finally with alcohol. It is important to employ air-free liquids, since the iodide under these conditions is readily oxidized. The crystals are dark rose-red, with a yellow

tinge; the powder is pale rose-red. P. Stoll found that the X-radiograms correspond with a cubic lattice of the calcium fluoride type. The elementary cube has the parameter $A=10.92$, and contains 4 mols. The arrangement is that indicated in connection with the corresponding chloride, Fig. 114. W. Biltz and E. Birk gave $a=10.93$ A., and G. B. Naess and O. Hassel, $a=10.91$ A., and 4.73 A. for the distance between the Co and I atoms. The subject was discussed by W. Biltz, and H. Hentschel and F. Rinne. W. Biltz and E. Birk gave 2.096 for the sp. gr. at $25^\circ/4^\circ$, and 198.0 for the mol. vol.; G. L. Clark and H. K. Buckner gave 2.36 for the sp. gr. The mol. vol. of the NH_3 -groups was also discussed by W. Hieber and E. Levy, W. Biltz and E. Birk, and W. Biltz. F. Ephraim found for the dissociation press., p mm., of the ammonia:

	143.5°	163°	170°	174.5°	184.5°	188.5°	193°	197.5°
p	92	182	245	292	440	515	605	730

and the results are indicated in Fig. 114. W. Biltz and B. Fetkenheuer said that the results of W. Peters are too low. W. Biltz and G. F. Hüttig found that the

FIG. 114.—Dissociation Pressures of the Cobalt Amminiodides.

dissociation temp. at 100 mm. press. is 141° . The heat of formation from cobaltous iodide is 16.43 Cals. per mol of NH_3 . The subject was discussed by W. Biltz and co-workers, G. L. Clark, and by F. Ephraim. When the hexammine is heated to 156° , and the containing vessel repeatedly evacuated, it passes into **cobaltous diamminiodide**, $\text{CoI}_2 \cdot 2\text{NH}_3$. This dark blue variety is considered to be the *stable* or α -form, or *cis*-form as contrasted with the malachite-green salt or *unstable* or β -form, or *trans*-

form which is obtained when the hexammine is heated at 92° , in vacuo, over sulphuric acid. The β -form is more readily decomposed by exposure to air than is the case with the α -form; and the β -form passes into the α -form when it is heated. The diammine forms solid soln. with the hexammine. The dissociation press. at 136.5° was 0.17 mm., and at 153.5° , 0.94 mm. The decomposition temp. for 100 mm. press. is 272° . The salt melts at 222° . W. Biltz and co-workers found that the heat of formation is 10.17 Cals. per mol of NH_3 . The subject was discussed by G. L. Clark, and W. Hieber and E. Levy; and the magnetic susceptibility, by W. Klemm and W. Schüth. In attempting to prepare **cobaltous monamminiodide**, $\text{CoI}_2 \cdot \text{NH}_3$, by heating a mixture of cobalt iodide and hexamminiodide, in theoretical proportions, only a mixture of cobalt iodide and diamminiodide was formed. According to H. Franzen and H. L. Lucking, when conc. soln. of cobalt iodide and hydrazine iodide are mixed, a rose-red, crystalline powder of **cobaltous dihydraziniodide**, $\text{CoI}_2 \cdot 2\text{N}_2\text{H}_4$, is formed. The chlorides and bromides under similar conditions furnish double salts. A better yield is obtained by mixing aq. soln. of cobalt iodide and hydrazine hydrate. The product is sparingly soluble in water, and freely soluble in acids.

According to P. Walden, cobalt iodide is soluble in **phosphoryl chloride**, and in **arsenic trichloride**, but nearly insoluble in **arsenic tribromide**. O. L. Erdmann said that cobalt iodide is readily soluble in **ethyl alcohol**; forming a blue soln. studied by W. R. Brode, F. L. Cooper, and A. Hantzsch and H. Carlsohn; the blue soln. formed with **ether** was studied by A. Hantzsch, and A. Hantzsch and H. Carlsohn. W. Eidmann, and A. Naumann found that the iodide is soluble in **acetone**; and A. Naumann, that it is soluble in **methyl acetate**. P. Walden measured the electrical conductivity of the soln. in **acetonitrile**. A. Naumann found that the soln. in **benzonitrile** is apple-green. P. Walden measured the conductivity of soln. in **methyl thiocyanate**, in **dimethyl sulphide**, and in **methyl sulphate**. B. Köhnlein observed no marked reaction with **propyl chloride**; F. Ephraim and R. Linn, and W. Hieber and co-workers studied the complex salt with **methylamine**, and also with **ethylamine**; F. Ephraim and R. Linn obtained no complex with **dimethylamine**; G. A. Barbieri and F. Calzolari, and F. Calzolari and U. Tagliavini obtained

complexes with **hexamethylenetetramine**; G. Spacu and G. Suci, and W. Hieber and co-workers with **ethylenediamine**; J. Frejka and L. Zahlova, with **diaminobutane**; W. Hieber and E. Levy, and W. Hieber and co-workers, with **aniline**; W. Hieber and co-workers, and R. Cernatescu and co-workers, with **phenylenediamine**; W. Hieber and F. Leutert, with **acetoxime**; F. Calzolari, with **caffein**; W. R. Brode, A. Hantzsch, W. Hieber and E. Levy, W. Hieber and F. Mühlbauer, W. Hieber and A. Woerner, A. Naumann and J. Schröder, E. G. V. Percival and W. Wardlaw, F. Schlegel, and R. F. Weinland and co-workers, with **pyridine**; E. G. V. Percival and W. Wardlaw, with **quinaldine**; and F. Blau, with **dipyridyl**, and with **phenanthroline**. E. Beckmann, and W. R. Brode observed that cobalt iodide is soluble in **quinoline**. M. R. Menz studied the complexes formed with **camphidine**; and A. Tettamanzi and B. Carli, with **triethanolamine**. C. Dufraisse and D. Nakae studied the catalytic action on the oxidation of **acraldehyde**, **benzaldehyde**, **furfuraldehyde**, **styrene**, and **turpentine**.

G. F. Campbell prepared **cesium cobaltous tetraiodide**, Cs_2CoI_4 , from soln. of the component salts in the ratio $\text{Cs} : \text{Co} = 1 : 4$ to 16. The green deliquescent crystals are whitened by decomposition when brought in contact with water or alcohol. Although **sodium cobaltous tetraiodide**, $2\text{NaI}_2 \cdot \text{CoI}_2$, has not been prepared, L. Cambi has obtained complexes with acetone, and acetic anhydride. A. Ferrari and A. Inganni observed that a continuous series of solid soln. is formed with cadmium and cobalt iodides, but no compound is formed. D. Dobroserdoff prepared **mercuric cobaltous hexaiodide**, $2\text{HgI}_2 \cdot \text{CoI}_2 \cdot 6\text{H}_2\text{O}$, in dirty red octahedra, by evaporating in vacuo a mixed soln. of the component salts. The crystals are like those of chrome alum; and A. Duboin likened them to those of the corresponding iron salt. The salt is decomposed by water; and it is soluble in alcohol, and acetone. D. Dobroserdoff also obtained **mercuric cobaltous tetraiodide**, $\text{HgI}_2 \cdot \text{CoI}_2 \cdot 6\text{H}_2\text{O}$, from the mother-liquor obtained in preparing the hexaiodide. The salt is not decomposed by water; F. Calzolari and U. Tagliavini obtained a complex salt with hexamethylenetetramine. A. Mosnier prepared **lead cobaltous hexaiodide**, $\text{PbI}_2 \cdot 2\text{CoI}_2 \cdot 3\text{H}_2\text{O}$, from soln. of the component salts; it is decomposed by water.

§ 21. Cobaltic Iodide and its Complex Salts

The higher iodide of cobalt—cobaltic iodide, CoI_3 —has not yet been isolated, but a remarkable number of stable complex salts of the ammine family has been prepared. The general properties are treated more fully in connection with the chlorides.

The CoA_6 or Hexammine Family.

E. Frémy,¹ and O. W. Gibbs and F. A. Genth prepared cobaltic hexammino-iodide, $[\text{Co}(\text{NH}_3)_6]\text{I}_3$, by precipitation from a soln. of a cobaltic hexammino-salt

FIG. 115.—The Cobalt Atom and its Surroundings.

- NH_3 -groups
- I-atoms (1st kind)
- I-atoms (2nd kind)

by a soln. of potassium iodide. S. M. Jørgensen obtained it by adding hydriodic acid to a soln. of the hexamminohydroxide. The orange-red to garnet-red crystals are hexakisoctahedra belonging to the cubic system, and they were described by F. M. Jäger, and W. Nowaki. The X-radiograms obtained by K. Meisel and W. Tiedje furnished data from which they derived the following structure. Each cobalt atom is surrounded by six nitrogen atoms of the six

NH_3 -groups arranged at the apices of an octahedron, Fig. 115, so that the distances between the cobalt and nitrogen atoms are 1.9 Å. These distances are exaggerated in Fig. 116. The cobalt atoms are also surrounded by two sets of iodine atoms—(i) eight iodine atoms of the first kind are arranged at the apices of a cube and at a distance of 4.7 Å. from the cobalt atom; and (ii) six iodine atoms of the second kind are arranged at the apices of another octahedron at a distance of 5.45 Å. from the cobalt atom. This gives a kind of structure which is a combination of the sodium chloride, and the calcium fluoride lattices. Each cobalt atom is arranged in the lattice as indicated in

Figs. 116 and 117. The systems about the different cobalt atoms, Fig. 115, belong in part to other cobalt atoms, and likewise also with the elementary cells, Figs. 116 and 117. As a result, there are, on the average, four $[\text{Co}(\text{NH}_3)_6]\text{I}_3$ -molecules per unit cell. The face-centred, cubic cells have an edge of length $a=10.91 \text{ \AA}$. R. W. G. Wyckoff and T. P. McCutcheon, G. Natta, O. Hassel and

Fig. 116.—The Arrangement of the Cobalt Atoms in the Lattice; and of the NH_3 -groups about each Cobalt Atom.

Fig. 117.—The Arrangement of the Different Atoms in the Face-centred Lattice.

G. B. Naess, and O. Hassel gave $a=10.88 \text{ \AA}$; H. Hentschel and F. Rinne, 10.91 \AA ; and P. Stoll, 10.92 \AA . Whilst K. Meisel and W. Tiedje calculated 1.9 \AA for the parameter between the Co and N-atoms, R. W. G. Wyckoff and T. P. McCutcheon gave 2.2 \AA ; H. Hentschel and F. Rinne, 1.64 to 1.91 \AA ; and P. Stoll, 4.1 \AA . G. B. Naess and O. Hassel studied the lattice structure. G. Natta gave for the calculated sp. gr., 2.83 ; F. M. Jäger found the sp. gr. to be 2.526 at 15° ; the mol. vol., 214.52 ; and the topic axial ratios $\chi : \psi : \omega = 5.9864 : 5.9864 : 5.9865$. W. Biltz and E. Birk, found the sp. gr. to be 2.746 at $25^\circ/4$, and its mol. vol. 197.3 ; and F. Ephraim and O. Schütz, sp. gr. 2.636 at 25° , and mol. vol., 205.6 . W. Biltz calculated the mol. vol. of the NH_3 -groups in the cobaltic hexamminoiodide to be 19 , whereas for the corresponding cobaltous salt it is 24 . Observations on the subject were also made by R. Klement, and E. Birk; and W. Biltz, E. Feytis, and L. C. Jackson studied the magnetic properties. P. Pascal, and E. Rosenbohm gave for the magnetic susceptibility, -0.323×10^{-6} mass unit.

S. M. Jörgensen found the iodide to be less soluble in water than the bromide. F. Ephraim and co-workers, and P. Mosimann observed that a sat. aq. soln., at 18° , contains 0.015 mol or 0.819 grm. per litre. F. Ephraim and P. Mosimann prepared a polyiodide, **cobaltic hexamminoenneaiodide**, $[\text{Co}(\text{NH}_3)_6]\text{I}_3.3\text{I}_2$, by the action of a soln. of iodine in potassium iodide on the hexamminochloride. When the brown needles are extracted with carbon disulphide, two-thirds of the iodine is removed. F. Ephraim found that when the hexamminoiodide is treated with liquid ammonia, or with gaseous ammonia at -21° , a reddish-yellow **cobaltic hexadecamminoiodide**, $[\text{Co}(\text{NH}_3)_6]\text{I}_3.10\text{NH}_3$, is formed, and this compound, at -15.5° , yields **cobaltic enneamminoiodide**, $[\text{Co}(\text{NH}_3)_6]\text{I}_3.3\text{NH}_3$; and at 14° , **cobaltic heptamminoiodide**, $[\text{Co}(\text{NH}_3)_6]\text{I}_3.\text{NH}_3$, which has a dissociation temp. of 45.5° . F. Ephraim and co-workers obtained reddish-brown crystals of **mercuric cobaltic hexamminopentaiodide**, $[\text{Co}(\text{NH}_3)_6]\text{I}_3.\text{HgI}_2$, of sp. gr. 3.550 at 25° , and mol. vol. 280.7 ; also **mercuric cobaltic hexamminoenneaiodide**, $[\text{Co}(\text{NH}_3)_6]\text{I}_3.3\text{HgI}_2.6\text{H}_2\text{O}$, in small, reddish-brown crystals; and **bismuth cobaltic hexamminoheptaiodide**, $[\text{Co}(\text{NH}_3)_6]\text{I}_3.\text{BiI}_3$, as a yellow precipitate. No **zinc cobaltic hexamminoiodide**, or **cadmium cobaltic hexamminoiodide** could be prepared, but stannous iodide with the hexamminoiodide forms brown crystals of presumably **stannous cobaltic hexamminoiodide**, which soon decompose. F. W. Bergstrom observed that no definite product is formed by the action of an ammonia soln. of potassium amide.

P. Pfeiffer and T. Gassmann,² and L. L. Lehrfeld heated cobaltic chloropentammino-chloride with 3 molar parts of monohydrated ethylenediamine until the mass became yellow, and then added potassium iodide to an aq. soln. of the product,

and obtained **cobaltic trisethylenediamineiodide**, $[\text{Co en}_3]\text{I}_3 \cdot \text{H}_2\text{O}$, in yellow crystals—the mother-liquid slowly deposited yellow, acicular crystals. F. M. Jäger prepared the same salt by the addition of potassium iodide to a soln. of the bromide, and in re-crystallizing the product from hot water, obtained dark red to reddish-brown crystals, which were rhombic bipyramids with the axial ratios $a:b:c = 0.8700:1:1.7399$, and had a sp. gr. of 2.270 at $25^\circ/4^\circ$. Observations on the crystals were also made by F. M. Jäger and P. Koets. J. Angerstein studied the absorption spectrum. P. Pfeiffer and T. Gassmann added that at 16° the aq. soln. contained 2.55 per cent. of the anhydrous iodide. A. Benrath and W. Kohlberg, and A. G. Bergmann found that the vap. press. measurements agreed with the existence of the *monohydrate*. P. Pfeiffer and M. Tilgner prepared **cobaltic trisethylene-diamineheptaoidide**, $[\text{Co en}_3]\text{I}_3 \cdot 2\text{I}_2$, in black, tabular or acicular crystals, by the heating of a soln. of the thiocyanate with an alcoholic soln. of iodine and potassium iodide, or by the action of a soln. of iodine and potassium iodide on the iodide. It forms yellow soln. with alcohol and pyridine; and is decomposed by dil. acids. G. Spacu and co-workers prepared **cobaltic trisethylenediaminechloroiodo-mercurate**, $[\text{Co en}_3]\text{Cl}(\text{HgI}_4)$; and **cobaltic trisethylenediamineiodomercurate**, $[\text{Co en}_3]\text{I}(\text{HgI}_4)$.

F. M. Jäger prepared the *dextro-salt*, and the *lævo-salt* by treating the corresponding bromides with a conc. soln. of potassium iodide. The rhombic bipyramids of the *dextro-salt* have the axial ratios $a:b:c = 0.8276:1:0.7386$, and of the *lævo-salt*, 0.8256:1:0.7395. The sp. gr. are, respectively, 2.289 and 2.288 at $25^\circ/4^\circ$. E. Rosenbohm gave -3.84×10^{-7} mass unit for the magnetic susceptibility of the *dextro-salt*. L. C. Jackson studied the magnetic properties; and F. M. Jäger, the optical properties. G. and P. Spacu prepared **silver cobaltic trisethylenediamineiodide**, $[\text{Co en}_3](\text{AgI}_2)_2\text{I}$; and **lead cobaltic trisethylenediamineiodide**, $[\text{Co en}_3](\text{PbI}_3)_3$. C. S. Borzekowsky prepared the *dextro-* and *lævo-forms* of **cobaltic hydroxylaminebisethylenediamineamminoiodide**, $[\text{Co}(\text{NH}_3)(\text{NH}_2\text{OH})\text{en}_2]\text{I}_3$.

P. Pfeiffer and T. Gassmann obtained optically inactive, or racemic **cobaltic tripropylenediamineiodide**, $[\text{Co pn}_3]\text{I}_3 \cdot \text{H}_2\text{O}$, by adding potassium iodide to an aq. soln. of the corresponding chloride. F. M. Jäger and H. B. Blumendal prepared cobaltic triscyclopentanediamineiodide by the action of sodium iodide on a soln. of the chloride; and the *dextro-salt*, and *lævo-salt*, by the action of sodium iodide on soln. of the corresponding optically-active chlorides. The golden-yellow needles, according to E. Rosenbohm, have a magnetic susceptibility of -0.391×10^{-6} . The magnetic properties were studied by L. C. Jackson. L. Tschugaëff and W. Sokoloff found that aq. soln., saturated at 25° , contains 5.98 per cent. of the iodide; and, according to P. Pfeiffer and T. Gassmann, one saturated at 16° contains 4.29 per cent. The salt is reprecipitated by potassium iodide; and potassium thiocyanate precipitates the corresponding thiocyanate. The *lævo-salt*, in brown needles, was prepared by L. Tschugaëff and W. Sokoloff by heating on a water-bath an aq. soln. of chloropentamminochloride and *l*-propyldiamine, and afterwards adding potassium iodide. An aq. soln. saturated at 25° contains 11.36 per cent. of the iodide—*i.e.* the solubility is nearly double that of the racemic salt. The sp. rotation of a 3.38 per cent. aq. soln. for Na-light is $[\alpha] = 23.63^\circ$. J. Frejka and L. Zahlova prepared **cobaltic trisbutylenediamineiodide**, $[\text{Co bn}_3]\text{I}_3$.

F. G. Mann and W. J. Pope obtained **cobaltic bistriaminopropanediammineiodide**, $[\text{Co}(\text{NH}_3)_2\text{ptn}_2]\text{I}_3$, in orange-yellow needles by the action of potassium iodide on a soln. of the chloride. The salt is not decomposed at 320° , it is less soluble in water than the chloride; and it is not soluble in alcohol. F. G. Mann prepared **cobaltic bisdiaminodiethylenediamminotriiodide**, $\text{Co}\{(\text{H}_2\text{N} \cdot \text{C}_2\text{H}_4)_2\text{NH}_2\}_2\text{I}_3$. A. Werner and C. Kreutzer, and A. Werner and R. Samanek prepared **cobaltic cis-bisethylenediaminediammineiodide**, $[\text{Co}(\text{NH}_3)_2\text{en}_2]\text{I}_3$, by the action of potassium iodide on a soln. of the nitrate at 60° . The garnet-red, rhombic plates are strongly refractive; 5.6 parts of water dissolve 1 part of the iodide at 23° . A. Werner and Y. Shibata prepared the *dextro-salt*, and the *lævo-salt*, in dark yellow needles by the action of ammonium iodide on the corresponding bromides. The sp. rotation for the *dextro-salt* is $[\alpha] = 29^\circ$, and for the *lævo-salt*, -28° . A. Werner and R. Samanek also prepared **cobaltic cis-bisethylenediaminediamminopolyiodide**. A. Werner and co-workers obtained **cobaltic trans-bisethylenediaminediammineiodide**, in brownish-yellow plates by the action of potassium iodide on the corresponding chloride. One part of the iodide dissolves in 40.86 parts of water at 23° . A. Werner and K. Dawe reported **cobaltic bispropylenediaminediammineiodide**, $[\text{Co}(\text{NH}_3)_2\text{pn}_2]\text{I}_3 \cdot \text{H}_2\text{O}$, by adding potassium iodide to a hot soln. of the corresponding chloride. The dark orange-red crystalline mass

gradually forms yellow needles. F. M. Jäger and H. B. Blumendal obtained **cobaltic ethylenediaminebis(cyclopentanediamine)iodide**, $[\text{Co}(\text{C}_5\text{H}_{12}\text{N}_2)_2]\text{I}_3$, in yellowish-brown needles, by fractional crystallization of the product of the action of sodium iodide on the corresponding chloride. P. Pfeiffer and T. Gassmann obtained **cobaltic propylenediamine-bisethylenediamineiodide**, $[\text{Co}(\text{en}_2\text{pn})\text{I}_3 \cdot 3\frac{1}{2}\text{H}_2\text{O}]$, in brownish-yellow needles, as in the case of the bromide. Water saturated at 16° contains 4.0 per cent. of the anhydrous salt. E. Rosenbohm said that the *dextro*-salt has a magnetic susceptibility of -0.385×10^{-6} . L. C. Jackson studied the magnetic properties. F. M. Jäger and H. B. Blumendal prepared **cobaltic cis-bisethylenediaminecyclopentaneiodide**, $[\text{Co}(\text{en}_2(\text{C}_5\text{H}_{12}\text{N}_2))\text{I}_3]$, by treating the corresponding chloride with sodium iodide. The brownish-red, rhombic bipyramids have the axial ratios $a : b : c = 1.7699 : 1 : 0.6494$. They also prepared the *dextro*-salt, and the *levo*-salt. F. M. Jäger obtained **cobaltic α -phenanthrolinebisethylenediamineiodide**, $[\text{Co}(\text{en}_2(\text{C}_{12}\text{H}_8\text{N}_2))\text{I}_3]$, by the action of sodium iodide on the chlorosulphate. The dark brown, triclinic crystals have the axial ratios $a : b : c = 0.6487 : 1 : 0.4692$. He also prepared the *dextro*-salt, and the *levo*-salt. R. Plischke, and W. A. Redeker prepared **cobaltic pyridine-bisethylenediamineamminiodide**, $[\text{Co}(\text{NH}_3)(\text{en}_2\text{py})\text{I}_3]$. F. M. Jäger and P. Koets obtained **cobaltic bistriaminotriethylaminesexiesethylenediamineiodide**, $[\text{Co}_3(\text{en}_3(\text{C}_6\text{H}_{18}\text{N}_4)_2)_2]\text{I}_3$, by the action of sodium iodide on the chloride, or of barium iodide on the sulphate. The blood-red, acicular or columnar rhombic crystals have the axial ratios $a : b : c = 0.6498 : 1 : 0.9959$. The crystals are dichroic—blood-red and orange-yellow. C. J. Dippel, and J. M. Jäger prepared **cobaltic trisdiaminopentaneiodide**, $[\text{Co}(\text{ptn}_3)\text{I}_3]$, with $\alpha\beta\delta$ - and $\beta\beta\delta$ -diaminopentanes.

S. M. Jørgensen³ prepared **cobaltic aquopentamminiodide**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{I}_3$, by neutralizing an aq. soln. of the corresponding hydroxide or carbonate with dil. hydriodic acid, and precipitating the salt with the conc. acid; and F. Ephraim, by adding potassium iodide to a conc. soln. of the corresponding chloride. The dark red octahedra or six-sided plates were found by G. Natta to have a structure similar to that of the hexamminiodide. The face-centred, cubic lattice has 4 mols. per cell, and the parameter is $a = 10.84 \text{ \AA}$. Each cobalt atom is at the centre of an octahedron, the vertices of which are occupied by the NH_3 - and H_2O -groups. The substitution of one of the NH_3 -groups by a H_2O -group produces a slight contraction in the lattice, which otherwise remains unaltered. O. Hassel, and O. Hassel and G. B. Naess also found a contraction of the lattice from $a = 10.88 \text{ \AA}$. to $a = 10.81 \text{ \AA}$. by the replacement of the NH_3 - by the H_2O -group. G. Natta calculated 2.81 for the sp. gr. F. Ephraim and O. Schütz gave 2.697 for the sp. gr. at 25° , and for the mol. vol. 201.3, corresponding with a vol. contraction of 55.8 per cent. in the formation of the compound. N. R. Dhar and G. Urbain measured the polarization tension—*vide* the hexamminochloride. P. Job studied the electro-metric titration of the soln. with silver nitrate.

S. M. Jørgensen observed that the iodide is less soluble than the bromide; and F. Ephraim and O. Schütz found that a sat. aq. soln. of the iodide has 0.155 mol per litre at 17.5° . S. M. Jørgensen said that at 100° , the aq. soln. in the presence of hydriodic acid, shows no inclination to pass into iodopentamminiodide. The aq. soln. gives no precipitate with hydrobromic acid, or with sodium dithionate, but precipitation occurs with potassium iodide, ferricyanide, chromate, and dichromate; dil. sulphuric acid forms an iodosulphate; hydrochloroplatinic acid gives a brown soln. which soon deposits platinic iodide. F. Ephraim found that at -18° in ammonia gas, the product approximates to **cobaltic aquopentadecamminiodide**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{I}_3 \cdot 10\text{NH}_3$, and as the temp. rises to 56° , all the ammonia is expelled. Various solid soln. are formed in between. F. Ephraim and P. Mosimann observed that neither **zinc cobaltic aquopentamminiodide**, nor **cadmium cobaltic aquopentamminiodide** is formed from a soln. of the component iodides, but yellowish-red needles of **mercuric cobaltic aquopentamminopentaoidide**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{I}_3 \cdot \text{HgI}_2$, are readily produced.

A. Werner prepared **cobaltic trans-aquobisethylenediamineamminiodide**, $[\text{Co}(\text{NH}_3)(\text{en}_2(\text{H}_2\text{O}))\text{I}_3 \cdot \text{H}_2\text{O}]$, in brownish-red prisms, by the action of potassium iodide on the corresponding bromide.

F. Ephraim reported **cobaltic diaquotetramminiodide**, probably $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]\text{I}_3$, to be formed in dark brown crystals with a violet tinge, by the action of potassium iodide on a soln. of the corresponding nitrate or chloride.

The CoA₅ or Pentammine Family.

A. Werner⁴ prepared **cobaltic iodopentamminiodide**, $[\text{Co}(\text{NH}_3)_5\text{I}]\text{I}_2$, by heating the aquopentamminiodide between 60° and 80°; and also by rubbing up the nitrate of the series with potassium iodide. The olive-green, crystalline powder was found by R. Klement to have a sp. gr. of 2.926 at 25°/4°, and a mol. vol., 179.4. E. Birk, and W. Biltz discussed the mol. vol. of the contained NH_3 -groups. F. Ephraim found that at 20° a litre of water dissolves 0.002 mol of the salt. The polarization tension was studied by N. R. Dhar and G. Urbain.

A. Werner obtained **cobaltic iodopentamminochloride**, $[\text{Co}(\text{NH}_3)_5\text{I}]\text{Cl}_2$, by rubbing up the nitrate with ammonium chloride and a little water, and then adding conc. hydrochloric acid to the cold aq. soln. The dark green, crystalline mass was found by R. Klement to have a sp. gr. 2.355 at 25°/4°, and a mol. vol. 145.2. The mol. vol. of the contained NH_3 -groups was discussed by E. Birk, and W. Biltz. R. Ephraim observed that a sat., aq. soln. at 20° has 0.0154 mol per litre. The cold, aq. soln. was found by A. Werner to give precipitates with nitric and hydrobromic acids, and with potassium iodide, chromate, or dichromate, but not with sulphuric acid, sodium dithionate, ammonium sulphate or carbonate, or with potassium cyanide or thiocyanate. A. Werner prepared **cobaltic iodopentamminobromide**, $[\text{Co}(\text{NH}_3)_5\text{I}]\text{Br}_2$, in an analogous manner. The yellowish-green, crystalline powder was found by R. Klement to have a sp. gr. 2.926 at 25°/4°, and a mol. vol. 179.4. E. Birk, and W. Biltz discussed the mol. vol. of the contained NH_3 -groups. F. Ephraim observed that a sat., aq. soln. has 0.00076 mol of the salt per litre at 20°.

F. Ephraim prepared **cobaltic bromopentamminiodide**, $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{I}_2$, by the action of potassium iodide on the bromide of the series. The dark violet, tabular crystals were found by R. Klement to have a sp. gr. 2.721 at 25°/4°, and a mol. vol. 175.6; F. Ephraim and O. Schütz gave 2.665 for the sp. gr. at 25°, and 179.3 for the mol. vol. This corresponds with a vol. contraction of 55.8 per cent. in the formation of the salt. E. Birk, and W. Biltz discussed the mol. vol. of the contained NH_3 -groups. F. Ephraim found that a sat., aq. soln. had 0.0101 mol per litre at 20°. J. N. Brønsted and co-workers discussed the solubility in water, and in methanol. E. Schmidt prepared **cobaltic bromoaquobisethylenediamineiodide**, $[\text{Co}(\text{en}_2(\text{H}_2\text{O})\text{Br})\text{I}_2 \cdot \text{H}_2\text{O}]$. C. S. Borzekowsky prepared the dextro- and lævo-forms of **cobaltic bromohydroxylaminebisethylenediamineiodide**, $[\text{Co}(\text{NH}_2\text{OH})\text{en}_2\text{Br}]\text{I}_2$.

S. M. Jörgensen obtained **cobaltic chloropentamminiodide**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{I}_2$, by treating a soln. of the corresponding nitrate with potassium iodide; or the chloride with sodium iodide. R. Klement gave 2.502 for the sp. gr. at 25°/4°, and 173.3 for the mol. vol.; F. Ephraim and O. Schütz gave 2.417 for the sp. gr. at 25°, and 179.3 for the mol. vol. The vol. contraction in the formation of the compound was also studied by W. Biltz, and E. Birk. F. Ephraim observed that a sat., aq. soln. has 0.0418 mol per litre at 19°. J. N. Brønsted and co-workers discussed the solubility in water and in methanol. S. M. Jörgensen, and F. Ephraim and P. Mosimann described a **cobaltic chloropentamminopolyiodide**, prepared by the action of a soln. of iodine in hydriodic acid on the corresponding carbonate, or of a soln. of iodine and potassium iodide on the nitrate. F. Ephraim found that by treating the salt with ammonia at -21°, **cobaltic chlorohenamminiodide**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{I}_2 \cdot 6\text{NH}_3$, is formed, and this, at -8°, passes into **cobaltic chlorohexamminochloride**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{I}_2 \cdot \text{NH}_3$. F. Ephraim and P. Mosimann, and S. M. Jörgensen obtained **mercuric cobaltic chloropentamminotetraiodide**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{I}_2 \cdot \text{HgI}_2$, in brown plates; S. M. Jörgensen, **mercuric cobaltic chloropentamminohexaiodide**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{I}_2 \cdot 2\text{HgI}_2$, in sparingly soluble, brown needles; and F. Ephraim and P. Mosimann, **bismuth cobaltic chloropentamminoctoidide**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{I}_2 \cdot 2\text{BiI}_3$, as a red, crystalline powder.

A. Werner and W. E. Boës obtained **cobaltic bromobisethylenediamineaminoiodide**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Br}]\text{I}_2 \cdot \text{H}_2\text{O}$, in reddish-brown needles, by the action of ammonium iodide on the corresponding dithionate. E. Berl prepared **cobaltic bromobisethylenediaminehydroxylamineiodide**, $[\text{Co}(\text{NH}_2\text{OH})\text{enBr}]\text{I}_3$. J. Meisenheimer and E. Kiderlen prepared **cobaltic chloroethylaminebisethylenediamineiodide**, $[\text{Co en}_2(\text{C}_2\text{H}_5\text{NH}_2)\text{Cl}]\text{I}_2$; **cobaltic trans-chloroallylaminebisethylenediamineiodide**, $[\text{Co en}_2(\text{C}_3\text{H}_5\text{NH}_2)\text{Cl}]\text{I}_2$, in dark violet-red plates, sparingly soluble in water; **cobaltic chloroanilinebisethylenediamineiodide**, $[\text{Co en}_2(\text{C}_6\text{H}_5\text{NH}_2)\text{Cl}]\text{I}_2$, in reddish-brown prisms, decomposed at 40° to 50° ; **cobaltic chlorotoluidinebisethylenediamineiodide**, $[\text{Co en}_2(\text{C}_6\text{H}_7\text{NH}_2)\text{Cl}]\text{I}_2$, in reddish-brown, six-sided prisms which decompose at 35° ; and **cobaltic chlorobenzylaminebisethylenediamineiodide**, $[\text{Co en}_2(\text{C}_7\text{H}_7\text{NH}_2)\text{Cl}]\text{I}_2$, in raspberry-red needles. R. Vogel prepared **cobaltic chloropyridinebisethylenediamineiodide**, $[\text{Co en}_2\text{py}]\text{Cl}]\text{I}_2$.

G. T. Morgan and J. D. M. Smith⁵ obtained **cobaltic hydroxypentamminoiodide**, $[\text{Co}(\text{NH}_3)_5(\text{OH})]\text{I}_2$, as a violet, crystalline powder, by treating the chloride with potassium iodide. M. Rosner obtained **cobaltic hydroxydipyridinetriamminoiodide**, $[\text{Co}(\text{NH}_3)_3\text{Py}_2(\text{OH})]\text{I}_2$. A. Werner prepared hydrated **cobaltic cis-hydroxyaquobisethylenediamineiodide**, $[\text{Co en}_2(\text{H}_2\text{O})(\text{OH})]\text{I}_2$. Brownish-red needles of the *monohydrate* are formed by adding pyridine to a dil. aq. soln. of the *cis*-diaquobisethylenediaminebromide, and then potassium bromide, and re-crystallizing the product from its aq. soln. R. Klement obtained the *dihydrate*, in small, brown crystals, by saturating with potassium iodide a cold, 10 per cent. aq. soln. of the corresponding phosphate. A. Werner obtained **cobaltic trans-hydroxyaquobisethylenediamineiodide**, by adding potassium iodide to an aq. soln. of a salt of the *trans*-diaquobisethylenediamine; or by heating *trans*-diaquobisethylenediaminechloride first with conc. potash-lye and then with potassium iodide. The reddish-brown plates are sparingly soluble in water.

The CoA₄ or Tetrammine Family.

H. J. S. King⁶ prepared **cobaltic dihydroxytetramminoiodide**, $[\text{Co}\{\text{Co}(\text{NH}_3)_4(\text{OH})_2\}_3]\text{I}_6$. H. Seibt prepared **cobaltic cis-difuobisethylenediamineiodide**, $[\text{Co en}_2\text{F}_2]\text{I}$, as a red, crystalline powder, by the action of sodium iodide on a soln. of difuobisethylenediaminefluoride; and **cobaltic trans-difuobisethylenediamineiodide**, in green needles, by the action of ammonium iodide on the corresponding fluoride. A. Werner obtained **cobaltic cis-dichlorotetramminoiodide**, $[\text{Co}(\text{NH}_3)_4\text{F}_2]\text{F}$, in greyish-blue needles, by rubbing up the corresponding dithionate with ammonium chloride, and treating a soln. of the product with potassium iodide. The salt decomposes on keeping. A. Werner, and A. Werner and A. Klein prepared **cobaltic trans-dichlorotetramminoiodide** as a siskin-green, soluble powder by the action of potassium iodide on the corresponding hydrosulphate. The sp. gr. found by F. Ephraim and O. Schütz is 2.342 at 25° , the mol. vol. is 138.7, and the vol. contraction during the formation of the compound is 57.8 per cent. The aq. soln. decomposes in a short time. S. M. Jørgensen, P. Larisch, and A. Werner and P. Larisch prepared **cobaltic cis-dichlorobisethylenediamineiodide**, $[\text{Co en}_2\text{Cl}_2]\text{I}$, by adding potassium iodide to a sat., aq. soln. of the corresponding chloride. P. Larisch found that the dark violet, crystalline powder dissolves in 100 c.c. of water at 1° . S. M. Jørgensen, P. Larisch, and T. S. Price and S. A. Brazier prepared **cobaltic trans-dichlorobisethylenediamineiodide**, from the corresponding chloride, by the addition of potassium iodide. According to P. Larisch, 0.250 grm. of the green, tabular crystals dissolves in 100 c.c. of water at 1° . G. and P. Spacu prepared double salts: **cadmium cobaltic dichlorobisethylenediamineiodide**, $[\text{Co en}_2\text{Cl}_2]_2\text{CdI}_4$; and **mercury cobaltic dichlorobisethylenediamineiodide**, $[\text{Co en}_2\text{Cl}_2]_2\text{HgI}_3$. C. Rix, and A. Werner prepared **cobaltic trans-dichloroethylenediamineaminoiodide**, $[\text{Co}(\text{NH}_3)_2\text{enCl}_2]\text{I}$, as a green to brown precipitate, by adding potassium iodide to a cold, aq. soln. of the corresponding chloride. The powder is sensitive to light.

G. and P. Spacu prepared the **polyiodides** $[\text{Co en}_2(\text{NO}_2)_2]\text{I}_4$; $[\text{Co en}_2(\text{CNS})_2]\text{I}_3$;

$[\text{Co en}_2\text{Cl}_2]\text{I}_3$; $[\text{Co en}_2\text{I}_2]\text{I}_3$; $\text{Co}[\text{Co en}_2(\text{OH})_2]_3\text{I}_3$; $\text{Co}[\text{Co en}_2(\text{OH})_2]_3\text{I}_6$; and $[\text{Co en}_3]\text{I}_3$.

A. Werner and A. Wolberg prepared **cobaltic trans-dibromotetramminoiodide**, $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{I}$, in greenish-brown prisms, by the action of potassium iodide on the corresponding chloride. The salt is sparingly soluble in water, and it decomposes when kept for a long time. A. Werner obtained **cobaltic cis-dibromobis-ethylenediamineiodide**, $[\text{Co en}_2\text{Br}_2]\text{I}$, in scales resembling graphite, by adding potassium iodide to a soln. of the corresponding bromide. M. L. Ernsberger and W. R. Brode studied the absorption spectrum. A. Werner and A. Grün prepared **cobaltic bromochloroaquatrimminoiodide**, presumably $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{ClBr}]\text{I} \cdot n\text{H}_2\text{O}$, as a brown precipitate, by the action of potassium iodide on a soln. of the corresponding bromide; and similarly with **cobaltic bromochloroaquoethylenediamineamminoiodide**, presumably $[\text{Co}(\text{NH}_3)\text{en}(\text{H}_2\text{O})\text{ClBr}]\text{I}$.

Complexes with Two or More Cobalt Atoms.

G. Vortmann⁷ prepared **cobaltic peroxo-decamminoiodide**, $(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5\text{I}_4$, by adding potassium iodide to an oxidized ammoniacal soln. of cobaltous chloride; or by triturating the corresponding nitrate with a sat. soln. of potassium iodide. The small, green needles are stable in air; and sparingly soluble in water. They are decomposed, with the evolution of oxygen, by a large excess of water.

A. Werner and E. Kindscher prepared **cobaltic diol-octamminoiodide**, $[(\text{NH}_3)_4\text{Co} \cdots (\text{OH})_2 \cdots \text{Co}(\text{NH}_3)_4]\text{I}_4 \cdot 2\text{H}_2\text{O}$, by the action of potassium iodide on a soln. of the corresponding chloride. The dark violet crystals decompose above 60° ; they are coloured brown by exposure to air; and are readily dissolved by water. J. V. Dubsy and H. Frank, and H. Frank obtained **cobaltic diol-quaterethylenediamineiodide**, $[\text{en}_2\text{Co} \cdots (\text{OH})_2 \cdots \text{Co en}_2]\text{I}_4$, as a brownish-red, crystalline powder, by the action of potassium iodide on a soln. of the bromide.

A. Werner prepared **cobaltic μ -amino-peroxo-quaterethylenediamineiodide**, $[\text{en}_2\text{Co}=(\text{NH})_2\text{O}_2=\text{Co en}_2]\text{I}_3 \cdot 5\text{H}_2\text{O}$, in small, brown needles, by rubbing up cobaltic μ -amino-peroxo-quaterethylenediaminebromide with aq. ammonia and then adding sodium iodide; and also by rubbing up the corresponding dithionate with a soln. of potassium iodide. The salt is not precipitated from aq. soln. by potassium or ammonium bromide. The *dextro*-salt and the *laevo*-salt were obtained by A. Werner and co-workers from the corresponding μ -amino-peroxo-salt, as above. The sp. rotation of 0.125 per cent. aq. soln. is $[\alpha] = \pm 160^\circ$.

A. Werner and F. Steinitzer obtained **cobaltic iminohexamminoiodide**, $\text{Co}_2(\text{NH}_3)_6(\text{NH})\text{Cl}_4$, by treating a warm, aq. soln. of diaquo- μ -amino-ol-hexammine-nitrate with hydriodic acid. The pale brown powder is sparingly soluble in cold water; and it is decomposed by warm water. A. Werner obtained **cobaltic μ -amino-ol-quaterethylenediamineiodide**, $[\text{en}_2\text{Co} \cdots (\text{NH}_2)(\text{OH}) \cdots \text{Co en}_2]\text{I}_4$, as a pale red, crystalline powder, by the action of sodium iodide on an acetic acid soln. of μ -amino-peroxo-quaterethylenediaminenitrate, adding sodium thiosulphate in excess, and salting out with sodium iodide. A. Werner obtained the *laevo*-salt from the corresponding μ -amino-peroxo-nitrate, as just indicated.

A. Werner, and I. Fürstenberg prepared **cobaltic μ -amino-diol-hexamminoiodide**, $[(\text{NH}_3)_3\text{Co} \cdots (\text{NH}_2)(\text{OH})_2 \cdots \text{Co}(\text{NH}_3)_3]\text{I}_3$, by the action of potassium iodide on a soln. of the bromide. The brownish-red needles are sparingly soluble in water, and the aq. soln. reacts neutral. The aq. soln. decomposes when heated.

A. Werner and G. Jantsch obtained **cobaltic diaquo-tetrol-quaterethylenediamineiodide**, $[\text{en}_2\text{Co}=(\text{OH})_2 \cdots \text{Co}(\text{H}_2\text{O})_2 \cdots (\text{OH})_2=\text{Co en}_2]\text{I}_4 \cdot 2\text{H}_2\text{O}$, by rubbing up a soln. of the sulphate with barium chloride, then with potassium iodide, and salting out the product from the aq. soln. by potassium iodide at 30° . The brownish-red powder is sparingly soluble in cold water, but readily soluble in hot water. It suffers no loss in weight over conc. sulphuric acid.

A. Werner prepared **cobaltic hexol-sexiesethylenediamineiodide**, $[\text{Co}\{(\text{OH})_2 = \text{Co en}_2\}_3]\text{I}_6 \cdot 3\text{H}_2\text{O}$, by the action of sodium iodide on a conc., aq. soln. of the corresponding nitrate. The violet-brown, crystalline powder is sparingly soluble in cold water, but it dissolves readily in hot water and at the same time is partially decomposed.

§ 22. Cobalt Sulphides

M. von Orłowsky,¹ O. Schumann, E. Schürmann, E. F. Anthon, E. V. Britzke and A. F. Kapustinsky, G. Tammann and H. O. von Himmelstjerna, and

FIG. 118.—Freezing-point Curves of the System: Co-S.

W. Guertler discussed the relative affinity of the metals of the iron group for sulphur. According to J. L. Proust, when sulphur is projected on to the red-hot metal, combination is attended by fusion, and the mass becomes incandescent. P. Berthier heated dry cobalt sulphate in a carbon crucible at a white-heat, and obtained what T. H. Hiortdahl regarded as **cobalt tetratrisulphide**, Co_4S_3 ; and T. H. Hiortdahl obtained the same product by passing hydrogen sulphide over red-hot cobaltic oxide. The grey, greyish-yellow, or brass-yellow product has a granular fracture. It dissolves in acids, with the evolution of hydrogen sulphide, and presumably hydrogen. It was also prepared by K. Jellinek and J. Zakowsky, and R. Scheuer. V. Caglioti and G. Roberti found that the structure resembles that of bornite, and corresponds with a cubic,

face-centred lattice having $a=9.91$ Å. K. Friedrich examined mixtures of cobalt with up to 33.6 per cent. of sulphur, and the results are summarized in Fig. 118. Cobalt alone separates from alloys rich in cobalt, and the f.p. curve falls to a eutectic at 879° and 26.6 per cent. of sulphur; it then rises to a maximum at 935° and 29.3 per cent. of sulphur, corresponding with the tetratrisulphide. This compound forms solid soln. with up to 72.3 per cent. of cobalt. The form of the curve indicates the existence of a compound CoS , but alloys of this composition lose sulphur at ordinary atm. press. At lower temp., there are indications of the formation of a **cobalt hexitapentasulphide**, Co_6S_5 —the composition may be Co_5S_4 . It was found that the mixtures become porous as the sulphur is increased and the colour passes progressively from cobalt-white to bronze-yellow. Only alloys with over 68.7 per cent. of cobalt are attracted by a magnet.

J. Middleton described a simple **cobaltous sulphide**, CoS , or **cobalt sulphide**, as occurring in steel-grey masses at the Khetri mines, Jaipur—also spelt Jeypoor, and Syepoore—Rajputana, India. Hence the mineral was called **jaipurite**—also **jeypoorite**, by W. A. Ross; **syepoorite**, by J. F. L. Hausmann, and J. Nicol; and **Graukobalterz**, by F. von Kobell. According to R. A. Cooper, the so-called mineral **modderite** is jaipurite. The evidence is not conclusive. J. Middleton said that the mineral is used by Indian jewellers for staining gold a delicate rose-colour. The sp. gr. is 5.45. According to F. R. Mallet, only cobaltite and danaite occur in the Jaipur locality, and the cobalt ore from the Khetri mines, sold to the Indian enamellers under the name of *sehta*, produces different shades of blue, not red, enamels on gold and silver. A. Breithaupt also described a mineral resembling linnæite from Reuss, in Rutenia, and hence called it **rutenite**. The compact,

silver-white to bronze-yellow material has a black streak, a hexahedral cleavage, an uneven fracture, sp. gr. 4.923, and hardness 4 to 5. M. Adam supposed that this mineral is the same as jaipurite; C. F. Plattner said that rutenite is a cobalt sulphide with very little nickel, and traces of arsenic.

J. L. Proust, and W. A. Lampadius observed that cobalt and sulphur unite with incandescence, when the mixture is heated. R. Scheuer said that 475° is a suitable temp., and if this temp. be exceeded very much, the product will have too small a proportion of sulphur. R. Schenck and E. Raub obtained cobalt sulphide by the action of sulphur dioxide on the metal at 700° . The reaction: $3\text{Co} + \text{SO}_2 = \text{CoS} + 2\text{CoO}$, is irreversible; they also obtained the sulphide by the action of cobalt sulphate on the metal at about 300° : $\text{CoSO}_4 + 4\text{Co} = \text{CoS} + 4\text{CoO}$ —the vap. press. is about 1 atm. at 540° .

A. Baumé obtained the sulphide by heating cobalt with an alkali and calcium sulphate. J. L. Proust also prepared the sulphide by dehydrating the hydrated sulphide, and also by the action of sulphur on cobalt oxide. E. Weinschenk obtained regular crystals of the sulphide by sublimation from a mixture of cobalt oxide, sulphur, and ammonium chloride, and also by heating a mixture of cobalt oxide and ammonium thiocyanate in a sealed tube at 180° . R. Scheuer obtained a mixture of sulphides— CoS_2 , Co_2S_3 , and CoS —by passing hydrogen sulphide over the oxide at a high temp.—at 500° , the disulphide predominates; at 650° , the hemitrisulphide; and at 700° , the hemitrisulphide and the monosulphide are present in about equal proportions. G. P. Schweder obtained the sulphide by reducing cobalt sulphate with hydrogen, carbon, or carbon monoxide; A. Mourlot, with carbon; and H. Rose, with admixed sulphur in an atm. of hydrogen. T. H. Hiortdahl obtained the sulphide in steel-grey, prismatic crystals by fusing a mixture of anhydrous cobalt sulphate, barium sulphide, and an excess of sodium chloride; and H. Baubigny, by heating a neutral soln. of cobalt sulphate, sat. with hydrogen sulphide, in a sealed tube. A. Carnot added that when hydrogen sulphide is passed over a heated cobalt salt, a mixture of sulphides is formed, not of constant composition. G. Geitner obtained the sulphide by heating cobalt sulphite in a sealed tube at 200° .

Solutions of cobalt salts, in the presence of free acid, are not precipitated by hydrogen sulphide, but, in the absence of free acid, **hydrated cobaltous sulphide** is precipitated. The formation of this hydrate by the action of hydrogen sulphide on a soln. of, say, cobalt acetate, by the action of water saturated with hydrogen sulphide on a slurry of cobalt hydroxide or carbonate, and by the action of an alkali sulphide on a soln. of a cobalt salt, was described by J. L. Proust, K. Jellinek and J. Zakowsky, L. L. de Koninck, L. Moser and M. Behr, O. Ruff and B. Hirsch, R. Scheuer, and A. Villiers. F. Strohmeier obtained a precipitate which filters readily by saturating with hydrogen sulphide 100 c.c. of a 0.1N-soln. of a cobalt salt, adding 5 c.c. of 5N- NH_4OH , and passing hydrogen sulphide into the boiling soln. The precipitate is washed with a hot soln. of 0.1N- NH_4NO_3 and 0.05N- $(\text{NH}_4)_2\text{S}$. According to H. Baubigny, the composition of the product of the action of hydrogen sulphide on neutral and feebly acidic soln. of cobalt salts depends on the concentration of the soln., on the nature of the acid—*vide* 10. 57, 9—on the concentration of the hydrogen sulphide in the soln., and on the time. Cobalt sulphide precipitates more quickly than nickel sulphide from neutral, and very feebly acidic soln., and in more acidic soln., nickel sulphide is precipitated more quickly. The error due to the incompleteness of the precipitation, with increasing acidity of the soln., is illustrated by Fig. 119, due to M. M. Haring and M. Leatherman. G. Bruni and M. Padoa studied the effect of increasing the conc. of the hydrogen sulphide in the soln. by working at press. above atmospheric.

FIG. 119.—The Effect of the Acidity of the Solution on the Precipitation of Cobalt Sulphide.

A. Terreil found that if acetates, citrates, tartrates, and salts of other organic acids be present, cobalt sulphide is precipitated from soln. of cobalt salts by hydrogen sulphide, and this the more rapidly, the less the acidity of the soln. All the cobalt is not precipitated if oxalates are present; and F. Field observed that tartaric or citric acid inhibits the precipitation of cobalt sulphide by hydrogen sulphide. The subject was discussed by F. Uebelhör, H. Vestner, L. L. de Koninck, L. L. de Koninck and M. Ledent, L. Bruner, H. Delffs, G. Chesneau, O. F. Tower, and A. Villiers—*vide* nickel sulphide. U. Dreyer and A. Richter obtained cobaltous sulphide by the action of sodium sulphide on a soln. of potassium cobaltic nitrite. O. W. Gibbs said that when a soln. of a cobaltous salt is treated with a boiling soln. of sodium sulphide, the precipitated sulphide is stable in air, and the precipitate is not soluble in an excess of colourless ammonium or sodium monosulphide, but with higher sulphides, the cobalt sulphide may dissolve—the soln. is stable in air, and it is not decomposed by boiling, or by the addition of sulphuric acid, but the sulphide is precipitated by ammonium chloride. According to W. Herz, cobalt sulphide prepared by precipitation from a soln. of cobalt nitrate, by ammonium sulphide, and washed by decantation with water, is, when freshly-prepared, soluble in dilute, say, 2*N*-hydrochloric acid, with the evolution of hydrogen sulphide. When the precipitate is exposed to air, it is partly converted into cobalt sulphate, and when treated with dil. hydrochloric acid, it partly dissolves without evolving hydrogen sulphide; the remainder of the cobalt sulphide is insoluble, presumably because it has been polymerized or coagulated—*vide* nickel sulphide. S. M. Kusmenko found that with mixtures of cobalt and zinc or manganese sulphates in gelatin, the less soluble sulphide is precipitated first by sodium sulphide. According to G. Chesneau, and R. Scheuer, when a soln. of a cobalt salt is treated with a soln. of an alkali polysulphide, sat. with sulphur, a black **cobalt hemiheptasulphide** is formed, approximating Co_2S_7 . The black crystals are said to be insoluble in a soln. of an alkali monosulphide, but soluble in a soln. of sulphur in alkali monosulphide.

A. Terreil, and F. J. Faktor observed that when sodium thiosulphate is added to a rose-red soln. of a cobalt salt, the colour becomes blue, and when the mixture is boiled, some cobalt sulphide is precipitated, and on evaporating the mixture and heating it to 100° or 120°, the conversion to sulphide is complete. O. W. Gibbs, and J. T. Norton observed that cobalt is quantitatively precipitated as sulphide when a cobalt salt is heated with sodium thiosulphate in neutral soln., or in soln. acidified with acetic acid, but not so if a mineral acid is present. O. Brunck found that sodium hyposulphite precipitates the sulphide from soln. of cobalt salts—particularly if the liquid be warm; the presence of ammonia favours the precipitation. R. Schiff and N. Tarugi found that ammonium thioacetate in ammoniacal, but not in acidic, soln. precipitates cobalt sulphide. E. Beutel and A. Kutzelnigg studied the anodic formation of sulphide films.

H. Vestner observed that with 0.001*N*- to 0.0001*N*-soln. of cobalt salts, hydrogen sulphide furnishes a **colloidal solution** of cobalt sulphide; and C. Winssinger prepared a colloidal soln. of cobalt sulphide by working with very dil. soln. and removing the soluble salts by dialysis. The greenish-brown hydrosol can be prepared only in very dil. soln., since it so easily flocculates; and it is readily oxidized by air. The preparation of the hydrosol was also described by A. Lottermoser. A. Müller employed glycerol to prevent the coagulation of the hydrosol, and J. Hausmann recommended gelatin as a protective colloid. The preparation of rhythmic rings by the diffusion of a soln. of sodium sulphide in gelatin associated with a cobalt salt, was discussed by J. Hausmann, S. M. Kusmenko, and O. F. Tower and E. E. Chapman; and F. E. Lloyd and V. Moravsek, and E. R. Riegel obtained rhythmic rings in silica gel. P. B. Ganguly and N. R. Dhar studied the coagulation of the colloidal soln. in light.

Precipitated cobalt sulphide is a black powder, but the silver-white crystals prepared by E. Weinschenk have a reddish tinge. According to N. Alsén, W. F. de

Jong and H. W. V. Willems, P. P. Ewald and C. Hermann, and V. M. Goldschmidt, the crystals of the anhydrous sulphide, like millerite, are trigonal, with $a=3.37$ Å., $c=5.14$ Å., and $a:c=1:1.52$. V. Caglioti and G. Roberti gave $a=3.38$ Å., $c=5.20$ Å., and $a:c=1:1.54$; the Co-S atoms are 2.33 Å. apart. The subject was discussed by A. Westgren, O. Stelling, and J. W. Gruner. J. Middleton gave 5.45 for the sp. gr. of jaipurite; and A. Breithaupt, 4.923 for the sp. gr. of rutenite. W. F. de Jong and H. W. V. Willems calculated 5.98 for the sp. gr. from the lattice constants. H. V. Regnault obtained 0.12512 for the sp. ht. between 13° and 98°. A. Mourlot found that the sulphur can be nearly all expelled by heating the sulphide in an electric-arc furnace. The m.p. of cobalt sulphide depends on the sulphur-content, and decreases as the proportion of sulphur is reduced, Fig. 117; K. Friedrich gave 1116° for the m.p. of CoS, and W. Biltz said that the m.p. exceeds 1100°. J. Thomsen gave for the heat of formation $(\text{Co}_2\text{S}, \text{Aq.})=21.71$ Cals., and M. Berthelot, 21.9 Cals.; and J. Thomsen gave for the reaction $[\text{Co}(\text{OH})_2, \text{H}_2\text{S}_{\text{aq.}}]=17.41$ Cals.; and for $[\text{Co}(\text{NO}_3)_2, \text{H}_2\text{S}_{\text{aq.}}]=-3.68$ Cals. The subject was discussed by G. Beck, and K. Jellinek and J. Zakowsky. W. Herz studied the entropy, and the vibration frequency. O. C. M. Davis and F. W. Rixon studied the relation between the heat of formation and the colour.

M. Kimura and M. Takewaki observed that cobalt sulphide strongly absorbs ultra-violet rays; A. Mickwitz studied the absorption spectrum; O. Stelling, the X-ray absorption spectrum; O. Rohde, and B. Aulenkamp, the photo-electric properties; and F. Trey, the electrolysis of the compressed powder. W. A. Lampadius, and G. Wiedemann said that cobalt sulphide is feebly ferromagnetic; T. H. Hiortdahl said that it is non-magnetic; and S. Veil observed that the magnetic susceptibility decreases with repeated heating under water at 120° to 210°. W. Klemm and W. Schüth found the mol. magnetic susceptibilities at 20°, 250°, 290°, 365°, and 425° to be, respectively, $\chi_{\text{mol.}} \times 10^6 = 557, 436, 443, (456),$ and 434 for a field of 2040 gauss.

According to H. Rose, if cobalt sulphide and sulphur be heated in hydrogen, the products obtained vary according to the temp.—cobalt disulphide, hemitrisulphide, and the monosulphide, and at a white-heat, *cobalt hemisulphide*, Co_2S . G. P. Schweder also noted the reduction of the heated sulphide by hydrogen. S. Miyamoto noted that the sulphide is reduced by hydrogen in the silent discharge. G. C. Winkelblech, H. W. F. Wackenroder, R. Scheuer, and W. Herz observed that moist, precipitated sulphide slowly oxidizes when it is exposed to air, with the formation of cobalt sulphate. P. de Clermont and H. Guiot observed that when the moist, freshly-precipitated sulphide is exposed to air, oxidation is not rapid enough to produce a rise of temp. such as occurs with nickel and manganese sulphides. O. W. Gibbs said that the dry sulphide is stable in air at ordinary temp., and oxidizes to sulphate only when it is heated. K. Friedrich observed that when the sulphide is heated in air, sulphur dioxide begins to be evolved at 684°; and in oxygen, at 708°, when the grain-size is 0.1 to 0.2 mm.; with increasing grain-size, the temp. of oxidation is raised. The sulphide does not decrepitate when heated at a low temp. F. Feigl showed that when boiled with animal charcoal in alkaline soln., cobalt sulphide is oxidized to sulphate by the oxygen adsorbed by the charcoal. A. Maifert found that ozone converts the sulphide first into sulphate, and then into sulphuric acid and cobalt peroxide.

T. H. Hiortdahl observed that water slowly transforms cobalt sulphide into the sulphate. H. V. Regnault, and F. Foreman found that at a red-heat, water vapour attacks the sulphide moderately; and J. A. McLarty, that with water vapour under press., cobalt oxide and hydrogen sulphide are formed. According to O. Weigel, water dissolves 41.62×10^{-6} mol of cobalt sulphide per litre, or 0.000379 per cent. L. Moser and M. Behr gave $10^{-9.28}$ mol per litre for the solubility in water, and 1.9×10^{-27} for the solubility product. A. Mickwitz calculated for the solubility, 0.3×10^{-5} to 1.0×10^{-5} per cent. metal cobalt. Observations were also made by L. Bruner and J. Zawadzky, and I. M. Kolthoff. J. L. R. Morgan

and A. H. Gotthalf found the relative solubility products of some sulphides, in mols per litre, in the presence of the S'' - and HS' -ions, contained in 0.1N- K_2S , to be Ni, 0.0191; Co, 0.0034; Cu, 0.00021; and Pb, 0.00024. A. Mickwitz found that in dil. soln., with Na_2S as precipitating agent, sat. soln. contain 0.3×10^{-5} per cent. of Co, and the precipitate is **cobalt hydroxyhydrosulphide**, $Co(OH)(HS)$, and when an excess of hydrogen sulphide is used as precipitant, there is evidence of the formation of **cobalt hydrosulphide**, $Co(SH)_2$. According to J. A. Arfvedson, if hydrogen be passed over red-hot cobalt sulphate, sulphur dioxide and water are evolved, and what was thought to be **cobalt oxysulphide**, Co_2OS , or $CoO.CoS$, is formed. When heated in air to redness, this product forms sulphur dioxide and cobaltic oxide; and with cold hydrochloric acid, cobalt oxide passes into soln., and cobalt sulphide remains; with the hot acid, some cobalt sulphide is also dissolved.

H. Rose found that cobalt sulphide is not attacked by chlorine in the cold, and the attack is slow when the sulphide is heated. E. Zielinsky studied the chloridizing of the sulphide. H. W. F. Wackenroder said that the precipitated sulphide dissolves in mineral acids when tolerably concentrated, but is very sparingly soluble in cold, dil. acids. E. Weinschenk observed that crystalline cobalt sulphide is attacked very slowly by conc. hydrochloric acid; and O. W. Gibbs, and L. L. de Koninck said that the sulphide is insoluble in dil. hydrochloric acid, but T. H. Hiortdahl said that it is soluble. Although cobalt and nickel sulphides are virtually insoluble in cold, dil. hydrochloric acid, neither is precipitated in the presence of that reagent by hydrogen sulphide; consequently, the sulphide probably changes into a less soluble form as soon as it has been precipitated—*vide* nickel sulphide. L. Moser and M. Behr found that freshly-precipitated, moist cobalt sulphide dissolves in hot or cold 0.5N-HCl, with the evolution of hydrogen sulphide; and air-dried cobalt sulphide dissolves partially in hydrochloric acid without giving off hydrogen sulphide. The air-dried sulphide is thus supposed to consist of sulphate mixed with insoluble, or polymerized sulphide. W. Herz noted that the precipitated sulphide becomes insoluble in 2N-HCl, as it is allowed to age. A. S. Komarowsky observed that the presence of a few drops of a 3 per cent. soln. of hydrogen dioxide makes cobalt sulphide dissolve very easily in 0.5N-soln. of mineral acids. P. Berthier observed that the moist sulphide dissolves in sulphurous acid; and J. Milbauer and J. Tucek, that the sulphide is oxidized by sulphur dioxide to form sulphate:

	500°	600°	700°	800°
Cobalt sulphate .	44.08	17.29	10.18	6.97 per cent.
Cobalt oxide .	—	53.75	71.29	91.93 „

H. Danneel and F. Schlottmann found that cobalt sulphide resists attack by sulphuryl chloride at ordinary temp., and at 300° to 350°, 5 to 9 per cent. is decomposed in one hour. L. Moser and M. Behr found that at 20°, a 2N-soln. of sulphuric acid, saturated with hydrogen sulphide, dissolves 1.72×10^{-4} mol of the cobalt sulphide per litre. V. Stanek observed that when the freshly-precipitated sulphide is heated with colourless ammonium sulphide in a sealed tube, at 200°, for 8 hrs., it suffers no perceptible change; but R. Popper found that cobalt sulphide is completely soluble in a soln. of ammonium polysulphide. P. de Clermont, and P. de Clermont and J. Frommel found that the sulphide is slowly decomposed by a boiling soln. of ammonium chloride.

G. P. Schweder observed that the sulphide is desulphurized when heated with carbon; and A. Mourlot noted the same thing in an electric furnace. F. Feigl found that the sulphide is oxidized to sulphate when boiled with water and bone charcoal. According to T. H. Hiortdahl, cobalt sulphide dissolves very slowly in acetic acid, but H. W. F. Wackenroder, and L. L. de Koninck said that the sulphide is scarcely soluble in dil. acetic acid. A. S. Komarowsky observed that in the presence of a little 3 per cent. soln. of hydrogen dioxide, the dissolution of the sulphide

in acetic acid proceeds very quickly. F. Field observed that the sulphide is slightly soluble in tartaric and citric acids. L. L. de Koninck said that the sulphide is not soluble in a cold soln. of potassium cyanide; and A. Guyard added that the freshly-precipitated sulphide is soluble in not very dil. soln. of potassium cyanide, and in this respect it differs from nickel sulphide—J. Haidlen and R. Fresenius said that a brownish-yellow soln. of a complex cyanide is formed. A. Guyard found that a hot soln. of alkali thiocyanate slowly dissolves the sulphide. B. L. Moldavsky and Z. I. Kumari studied the catalytic effect of the sulphide on the hydrogenation of thiophene.

N. Parravano and P. Agostini observed that aluminium, in the thermite process, reduces the sulphide to metal. J. B. Cammerer observed that a soln. of ferric chloride slowly transforms the sulphide into cobaltous chloride. E. Schürmann found that cobalt sulphide in contact with soln. of copper sulphate or lead nitrate is completely converted; partially decomposed in contact with soln. of zinc, nickel, or ferrus sulphate; and not decomposed by a soln. of manganese sulphate. E. F. Anthon observed that precipitated cobalt sulphide precipitates sulphides from aq. soln. of cadmium sulphate, lead acetate, ferric chloride, nickel nitrate, copper sulphate, and silver nitrate. C. Palmer and E. S. Bastin found that cobalt sulphide precipitates silver from a soln. of silver nitrate. According to R. Schenck and E. Raub, nickel reacts rapidly with sulphur dioxide at 550°, but equilibrium is established only after many days, complete conversion into nickel oxide and monosulphide being effected. The equilibrium is univariant, as there are three solid phases, but by removing part of the sulphur dioxide, one of these disappears and the equilibrium becomes bivariant. The three phases appear to be nickel oxide, nickel sulphide, and the γ solid solution; with low pressures of sulphur dioxide, the nickel sulphide phase disappears. The reverse reaction, with the formation of nickel from nickel oxide and sulphide, proceeds only as far as the solid solution phase below the m.p., at about 1400°; bundles of fine, hair crystals of this phase, or possibly of Ni_3S_2 , can be seen throughout the reacting mass in the early stages of this reaction.

H. de Sénarmont, and R. Scheuer prepared **cobaltosic sulphide**, Co_3S_4 , as a dark grey powder, by heating a soln. of cobalt chloride and ammonium polysulphide in a sealed tube at 160°. I. and L. Bellucci obtained it by keeping a mixture of cobalt carbonate, potassium carbonate and sulphur at a white-heat for a long time. W. F. de Jong and H. W. V. Willems obtained it by heating precipitated cobalt sulphide for 10 hrs. at 400° to 450° in a current of hydrogen sulphide. The X-radiogram coincides with that of linnæite, and it has a face-centred, cubic lattice $a=9.36 \text{ \AA}$, 8 mols. per unit cell; and a calculated sp. gr. of 4.86. The X-radiograms of G. Menzer indicate that the three minerals, linnæite, Co_3S_4 , polydymite, Ni_3S_4 , and sychnodymite, $(\text{Co,Cu,Ni})_3\text{S}_4$, are structurally the same; and M. N. Short and E. V. Shannon concluded that there are ternary and binary series of isomorphous mixtures in which the terminal members are ideal polydymite, ideal linnæite, and the unknown sulphomagnetite, Fe_3S_4 —*vide infra*. H. de Sénarmont found that cobaltosic sulphide is not attacked by dry air; and J. Joly noted that sulphur begins to be evolved near 480°. J. Lemberg found that a boiling sulphuric acid soln. of silver sulphate colours a section blue in about 5 mins.; and bromine in alkaline soln. produces a dark film in 15 mins. M. Leo observed that in a soln. of a salt of gold, a film of gold is deposited on the sulphide; and with a soln. of potassium bromate, it is blackened. E. F. Smith found that the sulphide is completely decomposed by sulphur monochloride in a sealed tube at 170°.

J. J. Berzelius, and L. R. von Fellenberg prepared **cobaltic sulphide**, Co_2S_3 , or **cobalt sesquisulphide**, by heating cobalt oxide strongly with sulphur and potassium hydroxide or carbonate, and washing the cold product—R. Schneider added that the cobaltic sulphide so obtained is impure. The sulphide is obtained by heating to bright redness, cobalt chloride with 12 times its weight of a mixture of equal parts of sodium carbonate, and sulphur. J. J. Berzelius obtained it by

heating cobaltic oxide not quite to redness in a current of hydrogen sulphide and J. A. Arfvedson, by passing hydrogen sulphide over red-hot cobalt oxysulphide. T. H. Hiortdahl, and R. Scheuer obtained cobaltic sulphide by heating a mixture of cobalt and sulphur preferably between 350° and 400° ; or by the action of hydrogen sulphide on cobaltic oxide between 600° and 650° —some cobalt monosulphide and disulphide are formed at the same time. R. Scheuer observed that yellow ammonium sulphide precipitates cobalt disulphide, along with a little cobaltic sulphide, from a cold soln. of a cobaltous salt; and when the mixture is boiled, with exclusion of air, cobaltic sulphide is formed in excess. E. M. Dingler observed that when an ammoniacal soln. of a cobalt salt is oxidized by air, and then treated with a yellow soln. of ammonium sulphide, hydrated cobaltic sulphide is precipitated; and the same product is obtained when a cobaltic hexammine or pentammine salt is similarly treated. Cobaltic sulphide appears in iron-grey, tabular crystals. F. W. Clarke reported that the sp. gr. is 4.8. I. and L. Bellucci said that cobaltic sulphide is non-magnetic, and when heated, gives off sulphur. It is not decomposed by water or by alkali-lye. L. R. von Fellenberg observed that when heated in chlorine, it is decomposed, forming sulphur and cobalt chlorides. R. Schneider found that it is slowly attacked by cold hydrochloric acid and aqua regia, and when boiled, sulphur separates out. According to H. Fleck, the hydrated cobaltic sulphide is not soluble in a soln. of potassium cyanide—*vide infra*, horbachite.

According to J. J. Setterberg, **cobalt disulphide**, CoS_2 , can be prepared by rapidly igniting the recently-precipitated carbonate, and heating to a little below redness a mixture of the product with 3 times its weight of sulphur—if the product is not black, it is again mixed with sulphur and ignited. L. Playfair and J. P. Joule used a similar process. I. and L. Bellucci obtained, not the disulphide, but only cobaltic sulphide by this process, and by keeping the temp. at a white-heat for a long period. Cobaltous sulphide is also obtained by passing hydrogen sulphide over cobaltic oxide at a temp. much below redness and boiling the dark grey mass with hydrochloric acid. R. Scheuer employed a temp. between 250° and 600° , and obtained the disulphide mixed with cobaltic and cobaltous sulphides. He also obtained it by heating a mixture of cobalt and sulphur to 175° to 225° . Yellow ammonium sulphide also produces this sulphide mixed with cobaltic sulphide when it is added to a hot or a cold soln. of a cobaltous salt. W. F. de Jong and H. W. V. Willems obtained the disulphide by heating powdered cobalt sulphide with sulphur at 160° for 30 to 40 hrs., and washing out the free sulphur with carbon disulphide. K. Johansson described cobaltiferous pyrite—**cobalt pyrite**, $(\text{Co}, \text{Fe})\text{S}_2$, of sp. gr. 4.965, and hardness 6.

The X-radiogram showed that the crystals are cubic, and of the pyrite type, with the parameter $a=5.64$ Å., the Co-S atoms are 2.38 Å. apart. The lattice structure was also discussed by J. W. Gruner, V. M. Goldschmidt, P. Niggli, and P. P. Ewald and C. Hermann. According to W. F. de Jong and H. W. V. Willems, the calculated sp. gr. is 4.55. According to L. Playfair and J. P. Joule, the sp. gr. is 4.269. J. J. Setterberg, and R. Scheuer found that the dull black powder gives off sulphur at a red-heat to form the grey monosulphide; it is not attacked by boiling alkali, or by acids, with the exception of nitric acid and aqua regia. The product obtained by the second process is oxidized to sulphuric acid and cobaltous sulphate when exposed, in a moist state, to air.

R. Schneider² melted cobalt, or a cobalt salt, with potassium carbonate and sulphur, and, on washing the cold product with water, obtained greyish-white, hexagonal plates mixed with a black, crystalline powder, but he was unable to separate the two. J. Milbauer melted cobalt oxide with five times its weight of potassium thiocyanate for half an hour at a red-heat, and washed the product with water. The dark grey mass had a metallic lustre, and under the microscope showed a crystalline structure. The analysis corresponded with **potassium cobalt decasulphide**, $\text{K}_2\text{Co}_{11}\text{S}_{10}$. It dissolves slowly in hydrochloric acid, and in aqua

regia in the cold; rapidly when heated. Hydrofluoric and sulphuric acids dissolve it only when warm. A soln. of ammonium sulphide, even when hot, has no action; organic acids, 12 per cent. hydrochloric acid, alkali-lye, and soln. of potassium cyanide, copper sulphate, and silver nitrate are without action. H. Brunner reported **sodium cobalt disulphide**, Na_2CoS_2 , to be formed as a yellow, crystalline mass, by heating cobalt oxalate with sodium thiosulphate. The product is easily oxidized in air. F. J. Faktor heated a mixture of anhydrous cobalt chloride and anhydrous sodium thiosulphate, and obtained a green mass which, when washed with water and alcohol, furnished **sodium cobalt pentasulphide**, $\text{Na}_2\text{Co}_4\text{S}_5$, as a black powder. I. and L. Bellucci obtained only cobalt sesquisulphide when mixtures of a cobalt salt, alkali hydroxide, and sulphur are fused at a high temp. A similar product was obtained in the corresponding attempt to prepare **barium cobalt sulphide**.

W. L. Faber described a mineral from the Patapsco mine in Carroll Co., Maryland, and he called it **carrollite**. Analyses by W. L. Faber, J. L. Smith and G. J. Brush, E. V. Shannon, W. F. de Jong and A. Hoog, and F. A. Genth correspond with **copper sulphocobaltite**, $\text{CuS} \cdot \text{Co}_2\text{S}_3$, or $\text{Cu}(\text{CoS}_2)_2$; it can also be regarded as a member of the group of **sulphomagnetites**, R_3S_4 , which includes *polydymite*, *linnaëite*, and *synchodymite*—*vide* nickel sulphides. The mineral occurs in octahedral crystals belonging to the cubic system, and it also occurs massive. Its colour is light steel-grey, with a faint reddish tint. Its fracture is uneven, approaching conchoidal, and the lustre is metallic. W. F. de Jong and A. Hoog observed that the X-radiograms are very similar to those of polydymite, and linnaëite. The face-centred, cubic lattice has eight R_3S_4 -, or CuCo_2S -molecules per unit cell; and the parameter $a=9.458 \text{ \AA}$. The sp. gr. is 4.85; and the hardness, 5.5.

W. Guertler and H. Schack found that lead and cobalt and their sulphides are incompletely miscible when molten; and in the system: $\text{Pb}-\text{Co}-\text{PbS}-\text{CoS}$, they observed the solid phases: $\text{Pb}+\text{Co}+\text{Co}_5\text{S}_4$; $\text{Pb}+\text{PbS}+\text{Co}_5\text{S}_4$; and $\text{Co}_5\text{S}_4+\text{CoS}+\text{PbS}$. M. Houdard heated a mixture of aluminium and cobalt in a current of hydrogen sulphide, and obtained golden-yellow spangles, which rapidly blackened. No definite **aluminium cobalt sulphide** was formed. F. Feigl reported **stannic cobalt sulphide** to be formed when a mixed soln. of stannic and cobalt salts is heated with hydrogen sulphide. W. Guertler, and W. Guertler and H. Schack made a study of a part of the ternary system: $\text{Pb}-\text{Co}-\text{S}$, but did not observe the formation of **lead cobalt sulphide**.

In 1746, G. Brandt³ found a ferruginous cobalt sulphide—"cobalt with iron and sulphuric acid"—at Bastnaes, near Riddarhyttan, Sweden; A. Cronsted called it *cobaltum ferro sulphurato mineralisatam*; C. Linnæus, *cobalt pyriticosum*; and B. G. Sage, and J. B. L. Romé de l'Isle, *mine de cobalt sulfureuse*, after W. Hisinger's analysis, which showed the mineral to be a cobalt sulphide. J. F. L. Hausmann called it *cobalt pyrites*; C. F. Rammelsberg called it *cobalt-nickel pyrites*; F. S. Beudant, *koboldin*; and W. Haidinger, **linnaëite**, after Linnæus. J. D. Dana described a nickeliferous variety from Siegen, Prussia, and called it *siegenite*—*vide infra*; and one from Müsen, Prussia, he called *musenite*.

The occurrences of linnaëite in Westphalia and the Rhine provinces were described by A. Breithaupt, C. Heusler, R. Hundt, H. Laspeyres, F. Roth, R. Scheibe, C. Schnabel, M. Schulze, and J. C. Ullmann; in Saxony, by A. Frenzel; in Siberia, by M. Websky; in Moravia, by F. A. Kolenati, and F. Kretschmer; in Great Britain, by A. Terreil and A. des Cloizeaux; in Sweden, by W. Hisinger, G. Leonhard, A. Erdmann, and J. J. Berzelius; at Katanga, Belgium Congo, by H. Buttgenbach; in the United States—Maryland and Missouri—by F. A. Genth.

Analyses were reported by T. Haege, F. C. Wernekinck, W. Witteborg, C. F. Rammelsberg, P. T. Cleve, G. Wolf, M. Legraye, and F. A. Genth. M. L. Frankenheim, and L. S. Randall gave the formula, $\text{CoS} \cdot \text{Co}_2\text{S}_3$, or Co_3S_4 ; C. F. Rammelsberg gave $2\text{RS} \cdot \text{RS}_2$, and later, R_2S_{11} , or $2\text{RS} \cdot 3\text{R}_2\text{S}_3$; P. Groth, and A. Schoep, $(\text{Ni}, \text{Co}, \text{Fe})(\text{Ni}, \text{Co}, \text{Fe})\text{S}_2\text{CoS}_2$, or $(\text{Co}, \text{Ni})_3\text{S}_4$; H. F. Collins, $(\text{Ni}, \text{Cu}, \text{Fe}, \text{Co})\text{S} \cdot \text{CoS}_2$;

W. Stahl, $(\text{Ni}, \text{Co}, \text{Cu}, \text{Fe})_4\text{S}_5$; and A. Eichler and co-workers, $5\text{Co}_3\text{S}_4 \cdot 6\text{NiS}_4$. The mineral linnæite was considered by M. N. Short and E. V. Shannon to be one of the terminal members, Co_3S_4 , of the ternary isomorphous series, $(\text{Co}, \text{Ni}, \text{Fe})_3\text{S}_4$, just as polydymite, Ni_3S_4 , is taken to be a second end-member, and Fe_3S_4 , a third end-member. The formula, $\text{CoS} \cdot \text{Co}_2\text{S}_3$, or $\text{Co}(\text{CoS}_2)_2$, makes linnæite analogous with the spinels, or a member of the *sulpho-spinels*.

Linnæite occurs in granular or compact masses as well as in octahedral crystals belonging to the cubic system. The fracture is uneven and almost conchoidal. The colour is pale steel-grey, or cream with a tinge of yellow, and it tarnishes to a yellowish-red, or to copper-red; the streak is blackish-grey; and the lustre is metallic. The cubic cleavage is imperfect. Twinning sometimes occurs about the (111)-plane, as in the spinels. F. Becke found that the corrosion figures are analogous to those of magnetite. The subject was also discussed by H. Baumhauer. The crystals were examined by C. Klein, J. C. Ullmann, M. Schulze, R. Scheibe, H. Laspèyres, R. Novacek, A. Terreil and A. des Cloizeaux, P. T. Cleve, and F. A. Genth. G. Menzer examined the X-radiograms of polydymite, linnæite, and sychmodymite, and found them almost identical. The face-centred, cubic lattice has the parameter $a=9.398 \text{ \AA}$.; and there are eight Co_3S_4 -molecules in the elementary cell. W. F. de Jong found $a=9.26 \text{ \AA}$. for linnæite from Littfeld; 9.42 \AA ., for that from Müsen. An artificial preparation, obtained by heating cobaltous sulphide in hydrogen sulphide at 400° to 450° for 10 hrs., was very like natural linnæite. G. Natta and L. Passerini found that the cubic lattice of Co_3S_4 and of Ni_3S_4 is of the spinel type, with $a=9.41 \text{ \AA}$. C. F. Rammelsberg gave 4.8 for the sp. gr.; P. T. Cleve, 4.755, and 4.825; C. Schnabel, 5.00; A. Eichler and co-workers, 4.85; H. Buttgenbach, 4.82; and I. I. Saslawsky, 4.808 to 4.816. The last-named also studied the mol. vol. W. F. de Jong calculated a sp. gr. 4.86 from the lattice data. The hardness is 5 to 6. H. Fizeau gave for the coeff. of thermal expansion $\alpha=0.041037$ at 40° . J. Joly gave 480° for the m.p. F. Beijerinck found that the linnæite is a good electrical conductor; and T. W. Case showed that an exposure of the mineral to light does not perceptibly affect its electrical resistance. E. T. Wherry found linnæite to be a fair radio-detector. J. Lemberg observed that an alkaline soln. of bromine attacks the mineral and produces a surface film of metal peroxide. E. F. Smith observed that the mineral is broken down by sulphur monochloride at 170° . Linnæite dissolves in nitric acid, with the separation of sulphur. J. Lemberg found linnæite is not readily coloured by a soln. of silver sulphate, but a blue coloration appears after a prolonged action at 100° .

The proportion of nickel in the linnæite of the Mine la Motte, Madison Co., exceeds that of the cobalt, and in that case M. N. Short and E. V. Shannon prefer the term **siegenite**, indicated above. The analysis agrees with $(\text{Fe}, \text{Co}, \text{Ni})_3\text{S}_4$; the mineral is isotropic; it has a cream colour with a tinge of yellow; no cleavage pits have been observed; with nitric acid a polished surface acquires a brown stain, and there is some effervescence; mercuric chloride gives indication of producing a brown stain in places; and negative results were obtained with hydrochloric acid, soln. of potassium cyanide and ferric chloride, and with potash-lye. These properties all resemble those of polydymite and of linnæite, but differ from violarite in the absence of a perfect cubic cleavage, and in the colour.

A. Knop⁴ described a mineral occurring with the chalcopyrite in the gneiss at Horbach, near St. Blasien, in the Black Forest. It was called **horbachite**. Analyses were reported by A. Knop, and E. Weinschenk. C. F. Rammelsberg represented the composition by the formula: $15\text{Fe}_2\text{S}_3 \cdot 4\text{NiS}_3$; and P. Groth and K. Mieleitner, by $\text{Fe}_8\text{Ni}_2\text{S}_{15}$, or $(\text{Fe}, \text{Ni})_2\text{S}_3$. E. Weinschenk regarded horbachite as a mixture of iron and nickel monosulphides, $(\text{Fe}, \text{Ni})\text{S}$, when $\text{Fe} : \text{Ni} = 3 : 1$ or $4 : 1$. The origin of the mineral was discussed by W. Sauer, and E. Beyschlag and co-workers. The colour of horbachite is dark bronze-brown or steel-grey. The streak is black. It occurs in crystalline masses, with an imperfect cleavage. The sp. gr. is 4.43; and the hardness, 4.5. F. Beijerinck said that the mineral

is a very good electrical conductor. The mineral readily decomposes under the influence of water and moisture, forming sulphates of iron and nickel.

W. Guertler⁵ discussed the nickel-cobalt sulphides. W. Guertler and H. Schack observed that cobalt pentitattetrasulphide, Co_5S_4 , and nickel tritadisulphide, Ni_3S_2 , form a continuous series of solid soln. above 475° ; below this temp., the mass is completely decomposed, with the separation of two new solid soln.

§ 23. Cobaltous Sulphate

F. A. C. Gren,¹ and W. A. Lampadius obtained a soln. of **cobaltous sulphate**, or simply **cobalt sulphate**, CoSO_4 , by dissolving the metal or the oxide in dil. sulphuric acid. An aq. soln. of cobaltous sulphate is obtained by dissolving the oxide, hydroxide, or carbonate in dil. sulphuric acid; and on evaporating the liquid at ordinary temp., the *heptahydrate*, $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$, crystallizes out—I. Koppel and H. Wetzel said that the heptahydrate crystallizes from the soln. below $40\cdot7^\circ$, and C. D. Carpenter and E. R. Jette, below $45\cdot1^\circ$.

Anhydrous cobaltous sulphate was prepared by E. Rothoff, and J. L. Proust by the dehydration of the hydrated salt at a dull red-heat; T. E. Thorpe and J. I. Watts recommended maintaining the hydrate at 250° until all the combined water has been expelled; and the Kali Forschungsanstalt observed it by heating a sat. soln. in an autoclave at 200° . The anhydrous salt was prepared by A. Étard, by boiling a soln. of the hydrated salt in conc. sulphuric acid; A. W. Davidson, by adding a little conc. sulphuric acid to an acetic acid soln. of cobalt nitrate; and by P. Klobb, by adding the hydrated salt to molten ammonium sulphate, and heating the mixture, protected from reducing gases, until the ammonium salt is all volatilized. C. Lepierre and M. Lachaud employed a similar process, and observed that when ammonium hydrosulphate is employed, instead of the normal salt, the cobalt sulphate furnishes fusiform, prismatic, hexagonal crystals, whereas with the normal salt, canary-yellow, octahedral crystals are formed. The difference is due to the presence of about 0.5 per cent. of free sulphuric acid in the fusiform crystals. A. Chatillon, H. P. Corson, R. Romer, T. Thomas, and R. Hocart and A. Serres prepared crystals of the salt; and F. Feigl and H. J. Kapulitzas obtained it from nickel-free oxide.

The heptahydrate occurs rarely as a mineral. The mineral was called *cobalt vitriol* by M. le Blanc, B. G. Sage, J. H. Kopp, and C. C. von Leonhard. It was also called *red vitriol*. F. S. Beudant proposed the name *rhodalose*—from $\rho\acute{o}\delta\acute{o}\epsilon\iota\varsigma$, rose-coloured, and $\alpha\lambda\varsigma$, salt—but this gave way to W. Haidinger's term *bieberite*, after the longest-known locality, Bieber, in Hesse, where it occurs in the rubbish of some old mines. C. F. Rammelsberg mentioned its occurrence in some mines at Siegen; F. Sandberger, at Alpirsbach; J. F. Vogl, at Joachimstal, Bohemia; A. Lacroix, at Chalanches, Dept. Isère, France; and W. J. Taylor, at Tres Puntas, Copiapo, Chili. C. M. Kersten noted the occurrence of the heptahydrate on specimens of cobalt speiss kept in museums. Analyses of bieberite were reported

by G. C. Winkelblech, C. F. Rammelsberg, F. S. Beudant, and J. H. Kopp; and of the heptahydrate, by J. L. Proust, E. Mitscherlich, and C. F. Bucholz.

I. Koppel and H. Wetzel found that, with sat., aq. soln., the heptahydrate is the solid phase up to 40°, and he estimated that the transition from the heptahydrate to the *hexahydrate*, $\text{CoSO}_4 \cdot 6\text{H}_2\text{O}$, occurs at about 40.7°, because J. C. G. de Marignac observed that the hexahydrate separates from the aq. soln. between 40° and 50°. The transition temp. is lowered in the presence of sodium sulphate. C. D. Carpenter and E. R. Jette gave 45.1° for the transition temp. E. Mitscherlich, W. Müller-Erzbach, and T. E. Thorpe and J. I. Watts said that the hexahydrate is obtained by crystallization from an aq. soln. of cobalt sulphate between 20° and 30°. R. Rhomer also prepared the hexahydrate. W. Müller-Erzbach said that the hexahydrate can be obtained by drying the heptahydrate over sulphuric acid; and L. de Boisbaudran also obtained the hexahydrate by carefully warming the heptahydrate, or by contact of the heptahydrate with a fragment of the hexahydrate—*vide infra*, the thermal decomposition of the sulphate. L. Playfair and J. P. Joule, G. N. Wyrouboff, T. E. Thorpe and J. I. Watts, and E. S. Larsen and M. L. Glenn reported the *pentahydrate*, $\text{CoSO}_4 \cdot 5\text{H}_2\text{O}$, by drying the heptahydrate or the hexahydrate over sulphuric acid. T. E. Thorpe and J. I. Watts obtained the *tetrahydrate*, $\text{CoSO}_4 \cdot 4\text{H}_2\text{O}$, by drying the powdered heptahydrate to a constant weight over sulphuric acid; H. O. Hofman and W. Wanjukoff, by passing a current of dry air over the heptahydrate; A. Fröhde, by adding conc. sulphuric acid to a conc. soln. of cobalt sulphate; and G. Vortmann, by heating cobaltic chloropentamminochloride with a little water and conc. sulphuric acid until all is dissolved, and then heating the mixture on a sand-bath at 220°. When, on cooling, the tetrahydrate separates out, the sulphuric acid is poured away from the crystalline powder, which is washed with cold water and alcohol, and dried on a porous tile. R. Rohmer prepared the tetrahydrate. G. Vortmann reported the possible existence of a *trihydrate*, $\text{CoSO}_4 \cdot 3\text{H}_2\text{O}$; and T. E. Thorpe and J. I. Watts, and L. Playfair and J. P. Joule said that the *dihydrate*, $\text{CoSO}_4 \cdot 2\text{H}_2\text{O}$, is formed by boiling the powdered heptahydrate with absolute alcohol; and M. A. Rakuzin and D. A. Brodsky, by allowing the higher hydrate to stand for some time over sulphuric acid. R. Rohmer also prepared the dihydrate. According to A. and H. Benrath, the solid phase in the aq. soln. at 97° is the *monohydrate*, $\text{CoSO}_4 \cdot \text{H}_2\text{O}$, which E. Woulf, H. Lescœur, and A. Étard prepared by mixing a conc. soln. of cobalt sulphate with cold, conc. sulphuric acid. R. Rohmer also prepared the monohydrate. T. E. Thorpe and J. I. Watts obtained the monohydrate by heating the heptahydrate to 100°; M. A. Rakuzin and D. A. Brodsky, by heating the heptahydrate 3 hrs. at 98°; F. Krafft, and A. Adolphi, by confining a higher hydrate in vacuo over phosphorus pentoxide; H. O. Hofman and W. Wanjukoff, by passing dry air over the heptahydrate at 58°; E. S. Larsen and M. L. Glenn, by drying the hexahydrate in a desiccator; G. Vortmann, from the mother-liquor after the preparation of the tetrahydrate; W. Ipatéeff and B. Zrjagin, by heating 1.5*N*- or 2*N*- CoSO_4 in a hydrogen or nitrogen atm. under press. at 150°, but J. H. Weibel added that in hydrogen or carbon monoxide, there is no separation at 150°, metal and oxide are precipitated at 250°, and metal only at 300°. The evidence of the chemical individuality of many of those hydrates is not very convincing. A. P. Rostkowsky's vap. press. curves show that only the hepta-, hexa-, and monohydrates are formed as chemical individuals. R. Reinicke studied the hydrates.

P. Klobb said that the **crystals** of the anhydrous salt are amaranth-red octahedra belonging to the cubic system. A. Étard, and C. Lepierre and M. Lachaud reported what they considered to be dimorphous forms—hexagonal and cubic—*vide supra*. R. Hocart and A. Serres found that the crystals of the salt dehydrated at 400° and 700° in ammonium hydrosulphate, are rhombic, with a space-lattice having $a=4.65$ Å., $b=0.71$ Å., and $c=8.45$ Å., and 4 mols. per unit cell. The dimensions of the lattices of the specimens are the same, but the structures and magnetic

properties are different. The carmine-red crystals of the heptahydrate were found by H. J. Brooke to be monoclinic with the axial ratios $a:b:c$ 1.1835:1:1.4973, and $\beta=104^\circ 55'$; and J. C. G. de Marignac gave 1.1815:1:1.5325, and $\beta=104^\circ 40'$. Observations were made by E. Mitscherlich. A. Rosenstiehl observed that the crystals of the heptahydrate are isomorphous with the corresponding heptahydrated zinc, manganese, iron, and nickel sulphates, and the subject was discussed by A. Arzruni, C. F. Rammelsberg, and E. S. von Fedoroff. J. M. Thomson noted the seeding of supersaturated soln. of magnesium sulphate with crystals of heptahydrated cobalt sulphate. E. S. Larsen and M. L. Glenn found the optic axial angle, $2V$, of the monoclinic tablets is near 90° ; M. W. Porter gave for $2V=88^\circ 1'$, and he noted cleavages on the (001)- and the (110)-faces. H. G. K. Westenbrink examined the X-radiogram and calculated for the cell parameters $a=15.45$ A., $b=13.08$ A., and $c=20.04$ A., and there are 4 mols. per unit cell. The red crystals of the hexahydrate were found by J. C. G. de Marignac to be monoclinic prisms with the axial ratios $a:b:c=1.3957:1:1.6976$, and $\beta=98^\circ 41'$. The crystals are isomorphous with the corresponding salts of magnesium and zinc. G. N. Wyruboff gave for the optic axial angle $2H_a=8^\circ$, and reported a possible dimorphous form. G. Roasio discussed the orientation of the crystals grown in a magnetic field. E. S. Larsen and M. L. Glenn found that the crystals of the pentahydrate are triclinic with a medium optic axial angle, $2V$. A. Fröhde said that the tetrahydrate furnishes a crystalline powder of a peach-blossom colour, and a similar remark was made by G. Wouff about the monohydrate; E. S. Larsen and M. L. Glenn obtained the monohydrate in fibres and crusts by evaporating an aq. soln. of the salt to dryness, whereas that obtained by the dehydration of the hexahydrate in a desiccator furnishes crystals with an optic axial angle having $2V$ nearly 90° .

According to L. Playfair and J. P. Joule, the **specific gravity** of the anhydrous sulphate is 3.531; O. Pettersson gave 3.614, 3.615 at 15.6° to 16° ; L. Playfair, 3.444; T. E. Thorpe and J. I. Watts, 3.472 at 157° ; and C. Lepierre and M. Lachaud, 3.65 for the octahedral crystals, and 3.64 for the prismatic crystals. E. Birk and W. Biltz gave 3.791 at $15^\circ/4^\circ$ for crystals dehydrated at a dull red-heat; G. L. Clark and co-workers, 3.710 at $25^\circ/4^\circ$ for crystals dehydrated at 280° ; and E. Moles and M. Crespi, 3.666 at $25^\circ/4^\circ$ for crystals dehydrated at 350° . H. Schiff gave 1.924 for the sp. gr. of crystals of the heptahydrate; O. Pettersson, 1.958 and 1.964 for crystals at 15.5° to 15.6° ; H. Schröder, 1.958; E. Gunther, 1.938; B. Gossner, 1.948; G. L. Clark and co-workers, 1.948 at $24^\circ/5^\circ$; M. H. Belz, 1.950; E. Widmer, 1.96 at 18° to 21° ; and E. Moles and M. Crespi, 1.930 at $25^\circ/4^\circ$. H. G. K. Westenbrink calculated the sp. gr. to be 1.889 from the lattice constants. For the hexahydrate, T. E. Thorpe and J. I. Watts gave 2.019 at $15^\circ/15^\circ$; B. Gossner, 2.000; and G. L. Clark and co-workers, 2.029 at $25^\circ/34^\circ$. For the pentahydrate, T. E. Thorpe and J. I. Watts, and L. Playfair gave 2.134; and E. Widmer, 2.2 at 18° to 21° . For the tetrahydrate, T. E. Thorpe and J. I. Watts gave 2.327 at $15^\circ/15^\circ$. For the dihydrate, T. E. Thorpe and J. I. Watts, and L. Playfair gave 2.712. For the monohydrate, T. E. Thorpe and J. I. Watts gave 3.125 at $15^\circ/15^\circ$; and E. Moles and M. Crespi, 3.076 at $25^\circ/4^\circ$. Determinations of the sp. gr. of aq. soln. were made by G. Charpy, F. Dreyer, A. M. Morrison, J. Wagner, W. W. J. Nicol, G. Quincke, R. W. Roberts, R. C. Cantelo and A. J. Berger, G. Jäger and H. Decker, W. Manchot and co-workers, and J. N. Rakshit. The *International Critical Tables* gave for soln. with C per cent. of CoSO_4 :

C .	.	.	1	2	4	6	8 per cent.
Sp. gr.	0°	.	1.0107	1.0215	1.0436	1.0662	1.0890
	25°	.	1.0072	1.0174	1.0380	1.0588	1.0800

B. Cabrera and co-workers gave for 0.2212 per cent. soln., 1.2638 $\{1-0.0327(\theta-20)\}$, and for 0.1478 per cent. soln., 1.1649 $\{1-0.0326(\theta-20)\}$. The **molecular volume**

of the salt was discussed by E. N. Gapon, R. C. Cantelo and H. E. Phifer, and J. A. Groshans. T. E. Thorpe and J. I. Watts studied the sp. vol. of cobalt sulphate and of its hydrates; E. Moles and M. Crespi, the mol. vol. of the water of hydration; and E. N. Gapon, the relation between the sp. gr., the m.p., and the ionization of salts. A. Baladin, and H. H. Stephenson studied the contraction which occurs in the formation of the anhydrous salt from its elements; A. Baladin, H. H. Stephenson, J. N. Rakshit, and G. L. Clark and co-workers, the contraction during the formation of the heptahydrate from the anhydrous salt and water; G. L. Clark and co-workers, and J. N. Rakshit, the contraction which occurs during the formation of the hexahydrate; J. N. Rakshit, the pentahydrate; G. L. Clark and co-workers, and J. N. Rakshit, the tetrahydrate; and J. N. Rakshit, the monohydrate. C. Charpy, and J. N. Rakshit studied the vol. contraction of the anhydrous salt when it is dissolved in water. F. Dreyer gave for the temp. of maximum density of aq. soln. with C per cent. of cobalt sulphate:

C	0	0.181	0.366	0.735	1.536	1.823 per cent.
Temp.	3.96°	3.70°	3.44°	2.92°	1.78°	1.43°

M. Torre measured the rate of **diffusion** of cobalt sulphate in water and found for the change in concentration, in grams of CoSO_4 per 100 c.c., after 24 hrs., with an initial conc. of:

Rate of diffusion	0.775 grm. per 100 c.c.			0.155 grm. per 100 c.c.		
	30°	40°	50°	30°	40°	50°
	0.194	0.322	0.450	0.041	0.065	0.087

E. Dittler discussed the diffusion of the salt in the crystalline form; and J. J. Coleman, aq. soln. G. Tamman discussed the relation of the mol. attraction to the **internal pressure**; S. Oka, the **surface tension** of the soln.; and Z. H. Skraup and co-workers, the capillary rise of the soln. in paper. R. C. Cantelo and A. J. Berger, and O. Pulvermacher made observations on the **viscosity**, and J. Wagner found for the relative values of the viscosity, water unity, at 25°:

CoSO_4	N	0.5N	0.25N	0.125N
η	1.3543	1.1590	1.0766	1.0402

and for soln. containing:

η	21.167 per cent. CoSO_4				7.239 per cent. CoSO_4			
	15°	25°	35°	45°	15°	25°	35°	45°
	1.9360	1.4620	1.1300	0.8995	0.8672	0.6872	0.5496	0.4508

H. Kopp found the **specific heat** of the heptahydrate between 15° and 80° to be 0.343. K. Jauch, and N. de Kolossowsky studied the subject. W. A. Tilden gave 96° to 98° for the **melting-point** of the heptahydrate; and E. N. Gapon studied the relation between the sp. gr., the m.p., and the ionization. L. Kahlenberg found the **lowering of the freezing-point** of aq. soln. containing 1.457 and 14.143 grms. of CoSO_4 per 100 grms. of water to be, respectively, 0.209° and 1.587°; and for soln. with 0.879, 10.54, and 17.58 grms., H. C. Jones and F. H. Getman gave, respectively, 0.143°, 1.187°, and 2.073°. Observations were made by F. Dreyer, and N. Tarugi and G. Bombardini. L. Kahlenberg measured the **raising of the boiling-point** of aq. soln. with 4.446, 9.596, 20.60, and 32.84 grms. of CoSO_4 per 100 grms. of water, and found, respectively, 0.110°, 0.262°, 0.568°, and 1.055°.

G. Wiedemann, W. Müller-Erbach, and H. Lescœur measured the **vapour pressure** of the heptahydrate, p mm., and C. D. Carpenter and E. R. Jette observed:

p	25.00°	40.18°	45.07°	45.17°	50.16°	55.29°	60.22°	65.16°	70.16°
	17.0	48.1	66.0	66.5	84.9	107.7	134.9	167.3	204.3

there is a transition point at 45.1°, where the vap. press. of the hepta- and the hexahydrates and of a sat. soln. are the same. Observations were made by W. C. Schumb. A. P. Rostkowsky gave for the heptahydrate, and the hexahydrate,

18 mm. at 25°. He observed evidence of the existence of only the hepta-, hexa-, and monohydrates. G. Tammann found the lowering of the vap. press. of aq. soln. with 10.55, 28.89, and 52.16 grms. CoSO_4 per 100 grms. of water to be, respectively, 7.5, 20.4, and 54.2 mm. Observations were also made by H. Lescœur, and I. Bencowitz and H. T. Hotchkiss. C. C. Tanner studied Soret's effect.

H. Baubigny and E. Péchard, and M. A. Rakuzin and D. A. Brodsky found that the **dehydration** of the heptahydrate readily occurs, with the loss of a mol. of water, to form the hexahydrate, by exposure to dry air; and L. de Boisbaudron noted that gentle warming of the heptahydrate has a similar result. M. A. Rakuzin and D. A. Brodsky observed that the dihydrate is formed over sulphuric acid. L. Hackspill and A. P. Kieffer, F. Krafft, and A. Adolphs found that the monohydrate is formed in vacuo over phosphorus pentoxide. T. E. Thorpe and J. I. Watts found that the heptahydrate is completely dehydrated at 250°, and that at 100°, the heptahydrate passes into the monohydrate. Observations were made by A. Étard, G. Vortmann, C. Gaudefroy, and M. Copisarow. F. Krafft said that the seventh mol. of water is retained by exposing the salt in the vacuum required for producing the cathode light. When gently heated in a current of dry air, the hydrated sulphate was found by H. O. Hofman and W. Wanjukoff to become anhydrous at 276°; E. Moles and M. Crespi said 220° to 260°; and for complete dehydration, A. Adolphs, K. Friedrich and co-workers, and L. Hackspill and A. P. Kieffer recommended 300° to 420° for complete dehydration—*vide supra*. P. Théodoridès gave 275° for the transition temp. of the monohydrate to the anhydrous sulphate.

P. Klobb observed no change in the anhydrous sulphate at ordinary temp., but at high temp., F. A. C. Gren, and J. C. G. de Marignac noted that the salt is decomposed into cobalt oxide, sulphur dioxide, and oxygen. According to J. L. Proust, the crystals of the heptahydrate give off water when heated, and become rose-coloured, but they do not lose sulphur trioxide at a red-heat. A. Ditte said that the **thermal decomposition** of the sulphate begins at 440°; G. Marchal, 690°; J. A. Hedvall and J. Heuberger, 940°; and K. Friedrich and A. Blickle gave 880° for the temp. of decomposition; and K. Flick, 905°, and 760 mm. press. W. N. Hartley observed that there is no evidence of decomposition at 300°, and that salt becomes lilac-coloured between 500° and a red-heat, but, on cooling, the original red colour of the salt is restored. O. Barth found the anhydrous sulphate to be stable at 600°; 3.4 per cent. decomposition can be detected after heating 3 hrs. at 615°; and complete decomposition occurred after heating 2 hrs. at 735°. H. O. Hofman and W. Wanjukoff gave 692° for the beginning of dissociation, and 720° to 770° for the temp. of complete dissociation. R. Schenck and E. Raub observed that the dissociation press. for $2\text{CoSO}_4 = 2\text{CoO} + 2\text{SO}_2 + \text{O}_2$, rises very rapidly in the vicinity of 900°. The temp. of decomposition is lowered appreciably in the presence of porcelain sherds. G. Marchal observed that the decomposition of the sulphate begins at about 690°, and that the partial press. of the gaseous constituents, p mm., and the total press., P mm., are:

	720°	800°	845°	900°	950°	1000°	1030°
P	1.15	3.8	9.18	29.1	67.4	144	217.7
p_{SO_3}	0.1	0.25	0.69	2.18	8.17	11.25	17.08
p_{SO_2}	0.7	2.36	6.07	17.95	41.49	88.50	133.74
p_{O_2}	0.35	1.18	3.03	8.97	20.74	44.25	66.87

H. H. Willard and R. D. Fowler based a method of separating the metals on the differences in the rates of thermal decomposition.

J. Thomsen gave for the **heat of formation** $(\text{Co}, \text{H}_2\text{SO}_4\text{Aq.}) = 19.71$ Cals.; $(\text{Co}, \frac{1}{2}\text{O}_2, \text{H}_2\text{SO}_4\text{Aq.}) = 88.07$ Cals.; $(\text{Co}, \text{O}_2, \text{SO}_2, 7\text{H}_2\text{O}) = 162.97$ Cals.; and M. Berthelot gave $(\text{Co}, \text{S}, 2\text{O}_2, 7\text{H}_2\text{O}) = 234.05$ Cals. R. Schenck and E. Raub gave 228.8 Cals. for the heat of formation of CoSO_4 . J. Thomsen gave for the **heat of neutralization** $(\frac{1}{2}\text{Co}(\text{OH})_2, \frac{1}{2}\text{H}_2\text{SO}_4) = 12.336$ Cals. G. Marchal gave 50.6 Cals. for the **heat of dissociation** of the anhydrous sulphate between 820° and 950°. J. Thomsen

gave for the **heat of solution** of a mol of the heptahydrate in 800 mols of water, -3.57 Cals.; and P. A. Favre and C. A. Valson gave -1.68 Cals. for the heat of soln. of the heptahydrate. T. E. Thorpe and J. I. Watts studied the relation between the sp. vol. of the various hydrates and the heat of soln.

The **index of refraction** of the heptahydrate was found by E. Widmer for Na-light to be 1.483 , and the molecular refraction 55.68 . According to E. S. Larsen and M. L. Glenn, the indices of refraction of the monoclinic heptahydrate are $\alpha=1.477$, $\beta=1.483$, and $\gamma=1.489$, the dispersion is feeble, and the optical character is negative. M. W. Porter gave $\alpha=1.4748$, $\beta=1.4820$, and $\gamma=1.4885$. E. S. Larsen and M. L. Glenn gave for the uniaxial hexahydrate, $\alpha=1.531$, $\beta=1.549$, and $\gamma=1.552$, and the optical character is negative. They gave for the triclinic pentahydrate, $\alpha=1.529$, $\beta=1.546$, and $\gamma=1.548$, and the optical character is negative. E. Widmer gave for the mean value in Na-light, 1.545 , and for the mol. refraction, 35.17 . The fibrous monohydrate has $\alpha=1.600$, and $\gamma=1.645$, and the crystals $\alpha=1.603$, $\beta=1.639$, and $\gamma=1.683$, and the optical character is positive. H. C. Jones and F. H. Getman measured the index of refraction of aq. soln. with C mols of CoSO_4 per litre, and found :

C . . .	0.0567	0.2267	0.6799	0.9066	1.1199	1.1333
μ . . .	1.32751	1.33248	1.34423	1.34974	1.35240	1.35588

Measurements were also made by L. R. Ingersoll, and R. W. Roberts. Observations on the **magnetic rotation** of the plane of polarization of aq. soln. were made by R. Wacksmuth, L. R. Ingersoll, M. Schérer and R. Cordonnier, F. Allison and E. J. Murphy, R. W. Roberts, and E. Miescher. W. Ackroyd and H. B. Knowles said that the heptahydrate is almost opaque to the **X-rays**. R. Robl observed no luminescence in **ultra-violet light**; and M. Trautz, no **triboluminescence**. T. Svensson studied the **photoelectric effect** with soln. of the sulphate; and P. Niggli, the reflexion maxima.

According to W. N. Hartley, the **colour** of the anhydrous sulphate is rose-red, or, according to G. L. Clark and co-workers, lavender-red. W. N. Hartley observed that the rose-red colour persists at 300° , but at 500° to a red-heat, it becomes lilac, and decomposition then begins. The original colours of the sulphate return on cooling. The presence of traces of nitrate, chloride, or ammonium salts make the salt red. Hot, conc. sulphuric acid does not change the colour of the salt, although F. G. Donnan and H. Bassett said that the boiling acid imparts a bluish tinge. M. Bamberger and R. Grengg observed that the colour of the heptahydrate at ordinary temp., is dark red; but at -190° , the colour is pale yellowish-red. A. H. Pfund added that there is a maximum reflection in the ultra-red at 9.05μ . The colour of dil. aq. soln. is rose-red, and that of conc. soln. is a deep red. H. M. Vernon, and M. Kahanowicz and P. Orecchioni studied the changes in colour which occur on dilution, and on raising the temp., when the colour becomes blue—*vide supra*, the colour of cobaltous chloride. The colour, and **absorption spectra** of soln. of cobalt sulphate were examined by P. Bovis, F. L. Cooper, A. Étard, A. Hantzsch, J. Hildebrand, R. Hill and O. R. Howell, R. A. Houston and co-workers, H. C. Jones and co-workers, J. Lifschitz and E. Rosenbohm, B. E. Moore, R. W. Roberts and co-workers, W. J. Russell, and P. Vaillant. A. Müller discussed the colour of a mixed soln. of cobalt and nickel sulphates.

E. Franke found the eq. **electrical conductivity**, λ , of soln. with a gram equivalent of the salt in v litres, at 25° , to be :

v . . .	32	62	128	256	512	1064
λ . . .	62.35	72.45	81.88	91.68	100.6	108.0

Observations were made by P. D. Chroustschoff, N. Tarugi and G. Bombardini, G. Vicentini, and R. C. Cantelo and A. J. Berger. H. H. Hosford and H. C. Jones, and H. C. Jones and co-workers gave for the mol. conductivity, μ , of soln. with a mol of the salt in v litres, when the temp. coeff. is a , and the degree of ionization, α :

v	2	16	32	128	512	1024	2048
μ { 0°	29.47	49.26	56.26	75.89	94.88	101.9	110.9
μ { 25°	55.10	91.97	105.4	143.4	180.2	196.9	214.1
α { $0^\circ-10^\circ$	0.97	1.63	1.88	2.56	3.21	3.57	3.75
α { $10^\circ-25^\circ$	1.06	1.76	2.02	2.79	3.55	3.95	4.38
α { $25^\circ-35^\circ$	1.04	1.74	2.04	2.87	3.79	4.23	4.51
α { 0°	26.6	44.4	50.7	68.4	85.6	91.9	100.0
α { 25°	25.7	43.0	49.2	67.0	84.2	92.0	100.0

R. C. Cantelo and E. C. Payne found that the **transport numbers**, n , of cobalt Co^{++} , in soln. of cobalt sulphate, are :

$N\text{-CoSO}_4$	0.233	0.753	1.444	1.860	2.833	3.994
n	0.396	0.373	0.316	0.286	0.260	0.149

It is assumed that complex ions are formed, and that the decreasing value of the transport numbers corresponds with an increase in the amounts of cobalt carried to the anode as complex ions. The subject was studied by R. W. Money and C. W. Davies, and H. C. Jones and co-workers. P. Vaillant calculated the **degree of ionization**, α per cent., from the conductivity data—*vide supra*. According to H. G. Denham, the degrees of **hydrolysis** and the **H^+ -ion concentration** of aq. soln. with a mol of the salt in v litres, at 25° , are :

v	2	4	8	16	32
$[\text{H}^+] \times 10^4$	0.313	0.210	0.163	0.107	0.093
Hydrolysis	0.0031	0.0042	0.0065	0.0085	0.0149

The hydrolysis with nickel sulphate is greater than with cobalt sulphate. M. le Blanc, P. Baumann, S. Labendzinsky; A. Coehn and M. Gläser, and H. W. Toepffer studied the **decomposition potential** of soln. of cobalt sulphate, and noted the anodic oxide formation at 1.248 volts with $N\text{-CoSO}_4$, and the evolution of oxygen at 1.448 volts. A. Coehn and M. Gläser found that in slightly alkaline soln., cobalt sulphate furnishes oxide at 1.21 volts; in slightly acidic soln., cobalt oxide is deposited on the anode at 1.52 volts; and in more strongly acidic soln., no oxide is deposited. The deposited oxide has the composition $\text{Co}_2\text{O}_3 \cdot n\text{H}_2\text{O}$ —with thin deposits, $n=2$, and with thick deposits, $n=3$. H. T. Kalmus and co-workers gave 2.16 volts for the decomposition potential of $N\text{-CoSO}_4$ with platinum electrodes; K. F. Ochs studied the **electromotive force** of the cells $\text{Pt}_{\text{platinized}} | \text{CoSO}_4, \text{H}_2\text{SO}_3 | \text{KI}, \text{I} | \text{Pt}$, and $\text{Pt}_{\text{platinized}} | \text{CoSO}_4, \text{H}_2\text{O}_2, \text{H}_2\text{SO}_4 | \text{KI}, \text{I} | \text{Pt}$; and H. G. Denham, the cell $\text{H}_2 | \text{CoSO}_4\text{aq.} | \text{NH}_4\text{NO}_3\text{aq.} | \text{Hg}_2\text{Cl}_2 | \text{Hg}$. H. Fresenius and F. Bergmann, and A. Gaiffe studied the **electrolysis** of soln. of cobalt sulphate with platinum electrodes—*vide supra*—and E. S. Hedges noted periodic fluctuations of the potential. J. Lifschitz observed the **Becquerel effect**. R. Saxon made some observations on the electrolysis of these soln.; and A. N. Schtschukareff studied the magnetic effect which occurs in the electrolysis of soln. of the sulphate.

The **magnetic properties** of the anhydrous sulphate were studied by G. Wiedemann, P. Plessner, P. Weiss and G. Foëx, E. Feytis, G. Jäger and H. Decker, M. H. Belz, A. Chatillon, R. Hocart and A. Serres, P. Krishnamurti, P. Hausknecht, T. Ishiwara, and K. Honda and T. Ishiwara. P. Théodoridès gave for the **magnetic susceptibility** of the anhydrous sulphate, $\chi = 62.25 \times 10^{-6}$ mass unit; A. Serres gave :

$\chi \times 10^6$	280.5° 66.91	364.5° 53.31	476.6° 42.10	594.6° 34.29	695.4° 29.75	728.5° 28.46
--------------------	-----------------	-----------------	-----------------	-----------------	-----------------	-----------------

and L. C. Jackson :

$\chi \times 10^6$	16.5° 62.21	-103.35° 96.96	-195.73° 169.7	-252.55° 378.8	-255.56° 420.7	-258.23° 461.8
--------------------	----------------	-------------------	-------------------	-------------------	-------------------	-------------------

According to P. Théodoridès, A. Chatillon, and A. Serres, the Curie point is near 0° ; P. Théodoridès observed an irregularity in the curve at 275° corresponding with the transformation of the monohydrate into the anhydrous salt. Observations

were made by T. Ishiwara, P. C. Ray and H. Bhar, N. S. Krishnan and co-workers, P. Weiss, B. Cabrera and co-workers, and L. C. Jackson and H. K. Onnes. G. Meslin gave 73.6×10^{-6} vol. unit for the magnetic susceptibility of the heptahydrate; and W. Finke gave 70.9×10^{-6} vol. unit in the direction of the a -axis, 64.0×10^{-6} vol. unit in the direction of the b -axis, and 68.5×10^{-6} vol. unit in the direction of the c -axis. P. Weiss and G. Foëx gave for the sp. susceptibility, $\chi = 31.9 \times 10^{-6}$ mass unit at 20° ; M. H. Belz, 33.85×10^{-6} mass unit at 16° . E. Feytis, L. C. Jackson and H. K. Onnes, A. A. Lutheroth, P. Weiss and E. D. Bruins, P. Weiss and G. Foëx, and B. Cabrera made observations on the subject; and L. C. Jackson gave:

	19°	-103.5°	-195.7°	-209.2°	-252.6°	-258.24°
$\chi \times 10^6$	37.0	61.6	126.9	144.6	403.0	535.9

L. C. Jackson's results for the reciprocal mol. susceptibility of the heptahydrate and

FIG. 120.—The Effect of Temperature on the Reciprocal Molecular Magnetic Susceptibility.

the anhydrous salt are summarized in Fig. 120. B. W. Bartlett studied the subject, E. Feytis gave for the monohydrate, $\chi = 53.6 \times 10^{-6}$ mass unit. G. Meslin observed that aq. soln. of cobalt sulphate are paramagnetic, and observations were made by G. Wiedemann. O. Liebknecht and A. P. Wills gave 65.6×10^{-6} mass unit at 18° ; G. Jäger and H. Decker, and S. Meyer, 58.1×10^{-6} mass unit at 18° ; G. Quincke, 73×10^{-6} mass unit at 18° to 20° ; P. Weiss and G. Foëx, 31.9×10^{-6} at 20° ; and G. Meslin, 34.5×10^{-6} at atm. temp. P. Vaillant, A. Quartaroli, B. Cabrera and co-workers, H. Stüdemann, C. Statescu, R. H. Weber, and A. Chatillon made observations on the

effect of the concentration of the soln. on the magnetic properties; and G. Jäger and H. Decker gave for soln. with C per cent. of CoSO_4 , at 20° :

C	1.172	0.938	0.703	0.293	0.117	0.023 per cent.
$\chi \times 10^{-6}$	-0.0032	-0.1419	-0.2805	-0.5340	-0.6456	-0.7148

The magneton numbers of the anhydrous salt were discussed by B. Cabrera, A. Chatillon, G. Foëx, L. C. Jackson, A. Serres, P. Théodoridès, and P. Weiss and G. Foëx; those of the heptahydrate, by B. Cabrera, and L. C. Jackson and co-workers; and those of the aq. soln., by A. Chatillon, A. Quartaroli, R. H. Weber, and P. Weiss and G. Foëx. The magnetic moment of the anhydrous salt was discussed by K. Honda and T. Ishiwara. W. Sucksmith studied the gyromagnetic effect. H. E. Armstrong and E. H. Rodd, and G. Roasio observed the orientation of the crystals of the heptahydrate grown in a magnetic field; and W. König, the effect of the deformation of gelatin cylinders containing the salt.

G. P. Schweder found that when the sulphate is heated in hydrogen, it is reduced to sulphide, provided the temp. is not too high; J. H. Weibel studied the reaction; and S. Miyamoto observed the reduction with hydrogen and the silent discharge. According to J. L. Proust, the crystals of the heptahydrate have a faintly astringent, slightly bitter, metallic taste; and G. Vortmann noted that the anhydrous salt in air is very hygroscopic. The heptahydrate effloresces in dry air, as previously indicated. E. S. Larsen and M. L. Glenn, H. Baubigny and E. Péchard, and A. P. Rostkowsky also noted the efflorescence of the hexahydrate in dry air. G. Vortmann noted that the monohydrate is rather less hygroscopic than the anhydrous salt. P. Klobb noted that the sulphate is not chemically changed by exposure to air at ordinary temp. A. Mailfert observed that with ozone, sulphuric

acid and a peroxide are formed. E. Brunner studied the oxidation of aq. soln. by ozone.

F. A. C. Gren, P. Klobb, and C. Lepierre and M. Lachaud noted that the anhydrous sulphate dissolves slowly in boiling water; and G. Vortmann added that the monohydrate dissolves more slowly than the anhydrous salt. G. J. Mulder, C. von Hauer, E. Tobler, C. L. Wagner, R. M. Caven and W. Johnston, C. Montemartini and L. Losana, A. and H. Benrath, and I. Koppel and H. Wetzel measured the solubility of cobalt sulphate, *S* grms. of CoSO_4 in 100 grms. of soln., and their results correspond with:

	0°	10°	20°	30°	40°	50°	60°	70°	80°	100°
<i>S</i> .	20.35	23.40	26.58	29.70	32.81	35.56	37.65	39.66	41.18	45.35

I. Koppel and H. Wetzel, in agreement with J. C. G. de Marignac, said that the heptahydrate is the solid phase up to 40.7° , when it passes into the hexahydrate. C. D. Carpenter and E. R. Jette gave 45.1 for this transition point; and A. P. Rostkowsky observed only the three hydrates—hepta-, hexa-, and monohydrates. P. Théodorides gave 215° for the transition temp., $\text{CoSO}_4 \cdot \text{H}_2\text{O} \rightleftharpoons \text{CoSO}_4 + \text{H}_2\text{O}$, based on magnetic observations; I. Koppel and H. Wetzel gave -3.0° for the eutectic temp. of the heptahydrate. A. Étard observed a decreasing solubility with a rise of temp. above 100 , and a soln. sat. at 15° begins to deposit a solid at about 145° , so that at 220° the soln. contains only 1 per cent. of salt, and at 250° the amount of salt in soln. approaches zero. According to K. Jableczynsky and co-workers, the rate of dissolution of the hydrate in water and non-aqueous solvents follows the rule characteristic of that for the less soluble solids. D. N. Bhattacharyya and N. R. Dhar, and N. R. Dhar noted the tendency of the salt to form supersaturated soln.

As indicated above, the salt is slightly hydrolyzed in aq. soln. A number of basic salts have been reported, although there is little to show which are chemical individuals, and which are mixtures. According to H. Fuchs, when cobaltous hydroxide is shaken with soln. of cobalt sulphate, until equilibrium is attained, the conc. of the soln. attains 25 grms. in 100 grms. of water, the solid phase assumes a constant composition for concentrations up to 30 grms. of cobalt sulphate per 100 grms. of water, and approximates **cobalt tetroxysulphate**, $\text{CoSO}_4 \cdot 4\text{CoO} \cdot 14\text{H}_2\text{O}$, or $[(\text{H}_2\text{O} \cdot \text{H}_2\text{O})_2 \cdot \text{Co} \cdot (\text{OCo} \cdot \text{H}_2\text{O} \cdot \text{H}_2\text{O})_4] \text{SO}_4 (\text{H}_2\text{O})_2$, in accord with the observations on the vap. press. of the *tetradecahydrate* that 4 mols. of water are lost over conc. sulphuric acid, to furnish the *decahydrate*, $[(\text{H}_2\text{O} \cdot \text{H}_2\text{O})_2 \cdot \text{Co} \cdot (\text{OCo} \cdot \text{H}_2\text{O})_4] \text{SO}_4 (\text{H}_2\text{O})_2$. At 100° , 4 mols of water were lost in 7 hrs., and $[(\text{H}_2\text{O})_4 \cdot \text{Co} \cdot (\text{OCo} \cdot \text{H}_2\text{O})_2] \text{SO}_4 (\text{H}_2\text{O})_2$ was formed. S. U. Pickering reported **cobalt trioxysulphate**, $4\text{CoO} \cdot \text{SO}_3$, to be formed by adding alkali-lye to soln. of cobalt sulphate. J. Habermann reported cobalt tetroxysulphate, $\text{CoSO}_4 \cdot 4\text{CoO} \cdot 4\text{H}_2\text{O}$, to be formed by adding aq. ammonia gradually to a boiling, neutral soln. of cobalt sulphate. The blue, flocculent precipitate is stable at ordinary temp. It loses some water at 150° , and all is lost at 288° to 292° , to furnish $5\text{CoO} \cdot \text{SO}_3$. W. Feitknecht found that the lattice of the salt of the type $\text{CoSO}_4 \cdot 3\text{Co}(\text{OH})_2$, consists of alternate layers of the normal salt and hydroxide. D. Strömholm reported **cobalt pentoxysulphate**, $6\text{CoO} \cdot \text{SO}_3 \cdot n\text{H}_2\text{O}$, to be formed by adding sodium hydroxide, carbonate, or hydrocarbonate to a soln. of cobalt sulphate; and N. Athanasesco, the decahydrate, $6\text{CoO} \cdot \text{SO}_3 \cdot 10\text{H}_2\text{O}$, as a bluish-green, crystalline powder, by boiling an aq. soln. of 5 grms. of cobalt sulphate with 1 or 2 grms. of calcium or barium carbonate, for 6 to 8 hrs., evaporating the liquid down to 40 c.c., and then heating the product in a sealed tube at 200° . A. Bernardi found that cobaltous sulphate behaves like the chloride (*q.v.*) towards sodium hydroxide, producing a green precipitate. R. Kuhn and A. Wassermann studied the action of the sulphate on **hydrogen dioxide**.

H. Wolfmann found that the salt in soln. in dil. sulphuric acid is oxidized by **fluorine** to cobaltic sulphate. F. Ephraim, and C. Hensigen observed that **hydrogen**

chloride does not attack anhydrous cobalt sulphate at ordinary temp. S. E. Moody found that the salt in boiling, aq. soln. is hydrolyzed by a mixture of **potassium iodide and iodate**: $3\text{CoSO}_4 + 5\text{KI} + \text{KIO}_3 + 3\text{H}_2\text{O} = 3\text{Co}(\text{OH})_2 + 3\text{K}_2\text{SO}_4 + 3\text{I}_2$. S. S. Bhatnagar and co-workers said that the reaction is not influenced by a magnetic field. Unlike ferrous hydroxide similarly formed, the precipitated cobaltous hydroxide is not oxidized. The action of **hydrogen sulphide** on a soln. of the salt was studied by G. Bruni and M. Padoa, and H. Baubigny and E. Péchard—*vide supra*. C. Montemartini and L. Losana studied the system with **sulphuric acid** and cobalt sulphate. H. Brintzinger and H. Osswald studied the complex sulphates, $[\text{Co}_2(\text{SO}_3)_4]^{4-}$. J. T. Norton found that when the sulphate is heated with **sodium thiosulphate** in a sealed tube, at 140° to 200° , cobalt sulphide and sulphur are formed. C. Dufraisse and D. Nakae studied the catalytic oxidation of soln. of **sodium sulphite** in the presence of cobalt sulphate. C. Montemartini and L. Losana studied the solubility of the salt in **sulphuric acid**, and in soln. of potassium sulphate; and A. B. Prescott, the decomposition of the sulphate by hydrochloric acid. C. Montemartini and L. Losana observed the formation of **cobalt hydrosulphate**, $\text{CoSO}_4\text{H}_2\text{SO}_4$, or $\text{Co}(\text{HSO}_4)_2$.

G. Gore, and E. C. Franklin and C. A. Kraus noted that anhydrous cobalt sulphate is insoluble in liquid **ammonia**. W. R. Hodgkinson and C. C. Trench studied the reduction of the sulphate heated in ammonia gas. H. Rose observed that the sulphate vigorously absorbs ammonia, to form **cobaltous hexamminosulphate**, $\text{CoSO}_4 \cdot 6\text{NH}_3$. The reaction is accompanied by the evolution of heat, to form a pale red, voluminous powder. The compound was also prepared by M. A. Rakuzin and D. A. Brodsky, G. L. Clark and co-workers, and E. Birk and W. Biltz. F. Ephraim said that the reaction is favoured by the condensation of the ammonia. E. Frémy obtained it by the action of ammonia on a conc., aq. soln. of cobalt sulphate while air is excluded, and then precipitating the salt with alcohol. E. Birk and W. Biltz found the sp. gr. to be 1.6545 at $25^\circ/4^\circ$, and the mol. vol. 155.5. F. Ephraim discussed the mol. vol. of the contained ammonia; and the dissociation press. of the ammonia, p mm., was found to be:

	66°	80.5°	90°	98.5°	102.5°	106°	109.5°
p	87	174	292	414	484	538	596

so that the dissociation temp. at 760 mm. works out to be 389.5° ; the calculated heat of formation is 73.9 Cals. per mol. of NH_3 . The powder is electrified when shaken. According to H. Rose, the salt is readily soluble in aq. ammonia; but it is hydrolyzed by water. When heated to redness, the salt melts, turns blue, evolves much ammonia, and gives a small sublimate of ammonium sulphite. D. M. Bose studied the magnetic properties; and G. Wiedemann found that the magnetic susceptibility is similar to that of ammonium cobaltous sulphate.

According to F. Ephraim, there is evidence of the formation of a higher ammine, probably the **decammine**, at very low temp. The **pentammine**, described by G. L. Clark and co-workers, could not be prepared by F. Ephraim. At temp. between 106° and 116° , the hexammine passes into violet-rose **cobaltous tetramminosulphate**, $\text{CoSO}_4 \cdot 4\text{NH}_3$. The dissociation press. of the tetrammine at 113.5° , 124° , and 135° are, respectively, 210, 404, and 656 mm., so that the dissociation temp. at 760 mm. is 409.5° . The heat of formation is 14.78 Cals. per mol. of ammonia. G. L. Clark and co-workers reported **cobaltous diaquotetramminosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]\text{SO}_4$, to be formed by passing ammonia into a hot, conc. soln. of cobaltous sulphate, and subsequently cooling the liquid; or by heating a mixture of 20 grms. of hydrated cobaltous sulphate, 40 c.c. of conc., aq. ammonia, and 10 c.c. of alcohol in a press. flask heated on a water-bath. The red crystals have a sp. gr. 1.804; and mol. vol. 143.67; and they are stable in dry air, but oxidize in moist air. F. Ephraim observed the formation of what is possibly **cobaltous triamminosulphate**, $\text{CoSO}_4 \cdot 3\text{NH}_3$, by heating a higher ammine between 132° and 135° , and **cobaltous diamminosulphate**, $\text{CoSO}_4 \cdot 2\text{NH}_3$, by heating a

higher ammine at 254°. The dissociation press. of the violet powder at 147° is 40 mm. If a higher ammine be heated between 254° and 257°, **cobaltous hemiamminosulphate**, $\text{CoSO}_4 \cdot \frac{1}{2}\text{NH}_3$, is formed. Its dissociation temp. exceeds 320°. G. Poma added a soln. of cobalt sulphate to a soln. of potassium iodide saturated with ammonia, and obtained rose-red **potassium cobaltous hexamminodiiodosulphate**, $2\text{KI} \cdot \text{CoSO}_4 \cdot 6\text{NH}_3$, which is easily oxidized in air; he also obtained the analogous **potassium cobaltous hexamminodibromosulphate**, $2\text{KBr} \cdot \text{CoSO}_4 \cdot 6\text{NH}_3$. O. R. Foz and L. de Boucher studied the amminosulphates.

T. Curtius and F. Schrader observed that a flesh-coloured precipitate is formed when **hydrazine hydrate** is added to a soln. of cobalt sulphate; and H. Franzen and O. von Mayer prepared **cobaltous trihydrazinesulphate**, $\text{CoSO}_4 \cdot 3\text{N}_2\text{H}_4$, in a similar manner. The buff, crystalline powder is insoluble in water; it is decomposed by boiling water; and is readily soluble in dil. acids and in aq. ammonia. P. C. Ray and H. Bhar found the magnetic susceptibility at 26° to be 35.9×10^{-6} mass unit. W. Feldt observed that when a soln. of **hydroxylamine sulphate** and cobaltous sulphate, in an atm. of hydrogen, is treated with an alcoholic soln. of hydroxylamine, rose-red, acicular crystals of **cobaltous diaquohydroxylamine-sulphate**, $\text{CoSO}_4 \cdot \text{NH}_2\text{OH} \cdot 2\text{H}_2\text{O}$, are formed. The salt is insoluble in cold water, but soluble in hot water. The hot, aq. soln. is quickly oxidized. W. Manchot and co-workers found that soln. with 12.217 and 24.433 grms. of CoSO_4 per 100 c.c. dissolve, respectively, 27.8 and 17.5 c.c. of **nitrous oxide**. F. L. Usher, and G. Hüfner studied the absorption of **nitric oxide** by soln. of cobalt sulphate. P. C. and N. Ray obtained a complex **cobaltous ethylphosphonium sulphate**, $\text{CoSO}_4 \cdot \{(\text{C}_2\text{H}_5)_4\text{P}\}_2\text{SO}_4 \cdot 8\text{H}_2\text{O}$. A. V. Pavlinova studied the oxidation of ammoniacal solutions of **arsenites** in presence of cobaltous sulphate as catalyst.

W. Manchot and co-workers found that soln. with 12.356 and 24.712 grms. of CoSO_4 per 100 c.c. dissolve, respectively, 0.94 and 38.0 c.c. of **acetylene**. G. P. Schweder noted that when heated with **carbon**, at not too high a temp., cobalt sulphate is reduced to cobalt sulphide. J. H. Weibel studied the action of **carbon monoxide**. C. A. L. de Bruyn found that 100 parts of absolute **methyl alcohol** dissolve 1.04 parts of anhydrous cobalt sulphate at 18°; and 54.5 parts of the heptahydrate at 18°, and 42.8 parts at 3°; also 100 parts of 93.5 per cent. methyl alcohol dissolve 13.3 parts of the heptahydrate at 3°; and 100 parts of 50 per cent. methyl alcohol dissolve 1.8 parts of the heptahydrate at 3°. Again, 100 parts of absolute **ethyl alcohol** dissolve 2.5 parts of the heptahydrate at 3°. G. C. Gibson and co-workers found the solubilities in methyl and ethyl alcohols, *S* gram. of CoSO_4 per 100 grms. of solvent, to be:

CH ₃ OH					C ₂ H ₅ OH			
	15°	25°	45°	55°	15°	25°	45°	55°
S	0.300	0.418	0.373	0.267	0.017	0.018	0.023	0.026

F. W. O. de Coninck found that **ethylene glycol** dissolves 3 to 3.2 per cent. of cobalt sulphate, and A. Grün and F. Bockisch obtained a complex salt, $\text{CoSO}_4 \cdot 3\text{C}_2\text{H}_6\text{O}_2 \cdot \text{H}_2\text{O}$; they also prepared a complex with **glycerol**, namely, $\text{CoSO}_4 \cdot 3\text{C}_3\text{H}_5(\text{OH})_3 \cdot \text{H}_2\text{O}$; and with **glycerol- α -monomethylin**, $\text{CoSO}_4 \cdot 2\text{C}_4\text{H}_{10}\text{O}_3$. C. Dufraisse and D. Nakae studied the catalytic oxidation of **acetaldehyde**, **benzaldehyde**, **furfuraldehyde**, **styrene**, and **turpentine** in the presence of cobalt sulphate. J. Persoz observed that **acetic acid** precipitates cobalt sulphate from its aq. soln., and F. L. Cooper studied the absorption spectrum of soln. in conc. acetic acid. A. W. Davidson found that the anhydrous sulphate is insoluble in a soln. of **ammonium acetate**. A. Naumann found that the heptahydrate is insoluble in **ethyl acetate**, and in **benzonitrile**. S. Hakomori studied the action of **oxalic acid**, and of **citric acid**. F. W. O. de Coninck observed that **glycol** can dissolve 2.5 per cent. of cobalt sulphate. A. Werner and W. Spruck, J. Meyer and K. Gröhler, and W. Hieber and co-workers studied the complex salt with **ethylenediamine**, $[\text{Co en}_3]\text{SO}_4$; J. Frejka and L. Zahlova, with **diaminobutane**; F. Calzolari, and

M. R. Menz, the complex salt with **hexamethylenetetramine**, $\text{CoSO}_4 \cdot \text{C}_6\text{H}_{12}\text{N}_4 \cdot 9\text{H}_2\text{O}$; M. R. Menz, with **camphidine**; and A. Rosenheim and co-workers, with **thiocarbamide**, $2\text{CoSO}_4 \cdot 3\text{CS}(\text{NH}_2)_2$. Boiling **aniline** was found by A. L. Leeds to have no influence on the anhydrous sulphate, and S. Glasstone and co-workers, and D. Tombeck obtained a complex, with aniline, namely, $\text{CoSO}_4 \cdot 4\text{C}_6\text{H}_5\text{NH}_2$; G. Spacu and R. Ripan, with **benzylamine**; J. Moitessier, and H. Schjerning, with **phenylhydrazine**; W. Hieber and co-workers, and R. Cernatescu and co-workers, with **phenylenediamine**; A. Smolka and A. Friedrich, with **phenylguanidine**; E. Thilo and H. Heilborn, with **diacetyldioxime**, $[\text{Co}(\text{CH}_3\text{CNOH})_2]\text{SO}_4$; F. Reitzenstein, F. Schlegel, R. F. Weinland and K. Effinger, A. Hantzsch, and G. Spacu and co-workers, with **pyridine**; G. Canneri, with **guanidine**; F. L. Hahn and co-workers, with **α -acetaminopyridine**; E. Borsbach, and F. Reitzenstein, with **quinoline**; P. C. and N. Ray, with **ethylsulphonium sulphate**, $\text{CoSO}_4 \cdot \{(\text{C}_2\text{H}_5)_3\text{S}\}_2 \cdot \text{SO}_4 \cdot 10\text{H}_2\text{O}$; W. Hieber and co-workers, with **trihydroxyethylamine**; K. A. Jensen and E. R. Madsen, with **thiosemicarbazide**; and A. Tettamanzi and B. Carli, with **triethanolamine**. A. V. Pavlinova studied the oxidation of ammoniacal solutions of **potassium ferrocyanide** in the presence of cobalt sulphate as catalyst.

G. Gore discussed the adsorption of cobalt sulphate from its aq. soln. by **silica**. R. Kremann and co-workers found that **zinc** or **cadmium** will precipitate cobalt from soln. of its sulphate; and that at room temp. the precipitate contains metal and hydroxide—the proportion of hydroxide decreases with a rise of temp., and increases with the ratio of the zinc or cadmium to the precipitated cobalt. T. Heymann and K. Jellinek studied the equilibrium with **nickel**: $\text{Ni} + \text{Co} \rightleftharpoons \text{Co} + \text{Ni}$; and R. Schenck and E. Raub represented the reaction with **cobalt**: $\text{CoSO}_4 + 4\text{Co} = 4\text{CoO} + \text{CoS}$. E. J. Mills and J. J. Smith studied the mutual precipitation of cobalt and nickel by hydroxides by adding **alkali-lye** to aq. soln. of their sulphates—*vide supra*, basic salts. G. Vortmann found that boiling alkali-lye has very little action on the monohydrated sulphate. J. A. Hedvall, and J. A. Hedvall and J. Heuberger found that moist strontium oxide begins to react with the anhydrous sulphate at 2° to 30° ; and the dry oxide, at 60° . The reaction with **baryta** begins at 328° ; with **strontia**, at 431° ; with **lime**, at 533° ; and with **magnesia**, at 592° . D. Balareff and B. Srebrow studied the reaction with baryta. R. Schenck and E. Raub studied the action of the sulphate on **cobalt sulphide** (*q.v.*); and O. Ruff and B. Hersch, the action of **ferrous sulphide**, and of **nickel hydroxide**. W. Meigen found that aq. soln. of cobalt sulphate, colour **calcite** blue; and **aragonite**, lilac. D. Längauer studied the system: $\text{CoSO}_4 + 2\text{KCl} = \text{CoCl}_2 + \text{K}_2\text{SO}_4$. J. L. Proust discussed the sympathetic ink (*q.v.*) made with a soln. of cobalt sulphate.

The double salts of cobalt sulphate.—J. L. Proust,² and E. Mitscherlich prepared **ammonium cobaltous disulphate**, $(\text{NH}_4)_2\text{Co}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$, by crystallization from a soln. of the component salts. A. and H. Benrath's study of the system: $\text{CoSO}_4 - (\text{NH}_4)_2\text{SO}_4 - \text{H}_2\text{O}$, is summarized in Fig. 121. The region of the 1:1:6 double salt is stippled, and Co_1 , Co_2 , and Co_3 refer, respectively, to the mono-, hexa-, and hepta-hydrates of cobalt sulphate. R. M. Caven and W. K. Gardner's observations on the ternary system, at 25° , are summarized in Fig. 122. The ruby-red crystals of the double salt are either short prisms, or more or less tabular; they were found by J. C. G. de Marignac to be monoclinic, with the axial ratios $a:b:c=0.7392:1:0.4985$, and $\beta=106^\circ 56'$; A. E. H. Tutton gave $0.7386:1:0.4975$, and $\beta=107^\circ 2'$. The crystals were also examined by J. Grailich and V. von Lang, and W. Hofmann. The optic axial angles observed by A. Murmann and L. Rotter were $2E=155^\circ 12'$, and $2V_a=81^\circ 39'$. A. E. H. Tutton gave:

	Li-	C-	Na-	Tl-	Cd-	F-light
$2E$. . .	$156^\circ 17'$	$156^\circ 35'$	$158^\circ 38'$	$160^\circ 47'$	—	—
$2H_a$. . .	$72^\circ 38'$	$72^\circ 36'$	$72^\circ 26'$	$72^\circ 16'$	$72^\circ 30'$	$72^\circ 3'$
$2H_o$. . .	$85^\circ 50'$	$85^\circ 46'$	$85^\circ 20'$	$84^\circ 54'$	$84^\circ 39'$	$84^\circ 20'$
$2V_a$. . .	$82^\circ 1'$	$82^\circ 2'$	$82^\circ 9'$	$82^\circ 17'$	$82^\circ 21'$	$82^\circ 27'$

The value of $2E$ for Na-light is $153^\circ 5'$ at 70° , corresponding with a decrease in the optic axial angle to the extent of 5.5° for a rise of temp. of 55° . F. Halla and E. Mehl examined the X-radiograms, and obtained for the parameters $a=9.23$ A., $b=12.49$ A., and $c=6.23$ A., and $B=106^\circ 56'$, and the elementary cell contains 2 mols. The pleochroism of the crystals was discussed by H. de Sénarmont, J. Müller, A. Murmann and L. Rotter, and C. Ehlers. H. Schiff gave 1.873 for the sp. gr.; F. L. Perrot, 1.88; O. Pettersson, 1.902 at 18° , and 1.907 at 16.6° ;

FIG. 121.—The Ternary System :
(NH_4) $_2\text{SO}_4$ - CoSO_4 - H_2O .

FIG. 122.—The Ternary System :
(NH_4) $_2\text{SO}_4$ - CoSO_4 - H_2O , at 25° .

H. Schröder, 1.893; R. Krickmeyer, 1.905 at $18^\circ/4^\circ$; F. Halla and E. Mehl, 1.899 to 1.909 at $25^\circ/4^\circ$; and A. E. H. Tutton, 1.901 at $20^\circ/4^\circ$, and for the mol. vol. 206.40. J. A. Groshaus, and O. Pettersson studied the mol. vol. and the contraction which attends the formation of the salt. B. Bertisch studied solid soln. of copper and cobalt ammonium sulphates. A. E. H. Tutton gave for the topic axial ratios, or the mol. distance ratios, $\chi:\psi:\omega=6.1860:8.3753:4.1667$. G. Quincke found the sp. gr. of a 12.64 per cent. soln. to be 1.1055. A. E. H. Tutton found that the salt, when heated, gives off water without melting. R. M. Caven and J. Ferguson found the vap. press., p mm., of the hexahydrate to be :

	35.3°	43.8°	50.7°	61.7°	67.3°	82.2°
p	5.7	11.8	19.3	41.2	58.7	140.9

or $\log p=7.600+3329T^{-1}-1,039,000T^{-2}$ as it passes to the dihydrate. The heat of hydration of the dihydrate is 74.8 Cals. per mol. of water vapour at 50° , and 1.03 Cals. per mol. of liquid water. E. Rouyer studied the mol. raising of the b.p. of aq. soln., and found indications of a marked dissociation of the double salt at 100° . C. Schaefer and M. Schubert observed maxima in the reflection at 9.15μ , and 16.18μ , and the first maximum when taken parallel to the a -axis, is at 9.15μ ; to the b -axis, 9.21μ ; and to the c -axis, 8.83μ . A. E. H. Tutton found the refractive indices to be, for :

	Li-	C-	Na-	Tl-	Cd-	F-	G-light
α	1.4871	1.4876	1.4902	1.4930	1.4946	1.4964	1.5018
β	1.4922	1.4927	1.4953	1.4982	1.4998	1.5014	1.5067
γ	1.5001	1.5006	1.5032	1.5060	1.5076	1.5094	1.5148

The mean value for Na-light is 1.4962; and the double refraction, $\gamma-\alpha=0.0130$. E. Widmer gave 1.4962 for the mean value in the Na-light; and H. de Sénarmont, 1.492. A. Murmann and L. Rotter, for yellow-light, $\alpha=1.489$, $\beta=1.494$, and $\gamma=1.501$; and $\beta=1.492$ for red-light, and 1.497 for green-light. A. E. H. Tutton gave $\beta=1.4826+441,773\lambda^{-2}+449,400,000,000\lambda^{-4}+\dots$. The index α is reproduced if the constant 1.4826 is reduced by 0.0051; and the index γ , if the constant 1.4826 is increased by 0.0079. Observations at 70° show that the values of α are diminished by about 0.0020, and the values of γ by about 0.0025 for 55° rise of temp. The sp. refractions for the μ^2 -formula for the $C(H_a)$ and H_γ (near G)-rays are, respectively, $\alpha=0.1515$, and 0.1552; $\beta=0.1528$, and 0.1565; and $\gamma=0.1549$,

and 0.1586; the corresponding mol. refractions are $\alpha=59.43$, and 60.89 ; $\beta=59.95$ and 62.22 ; and $\gamma=60.77$, and 62.22 ; or with the μ -formula and the C -ray, $\alpha=100.64$, $\beta=101.70$, and $\gamma=103.33$ -mean 101.89 ; the sp. dispersions for the μ^2 -formula and the G - and C -rays are $\alpha=\beta=\gamma=0.0037$; and the mol. dispersions $\alpha=1.46$, and $\beta=\lambda=1.45$. C. Ehlers discussed the absorption spectrum of the solid; and W. W. Coblentz, the absorption spectrum of the soln.; L. R. Ingersoll, and R. W. Roberts studied the magnetic rotation of the plane of polarization; and W. L. Goodwin, the feeble transparency for X-rays. Observations on the magnetic susceptibility were made by G. Wiedemann, and N. S. Krishnan and co-workers. W. Finke gave for the susceptibilities of the hexahydrate in the three axial directions, a , b , and c , respectively, 55.95×10^{-6} , 43.55×10^{-6} , and 45.50×10^{-6} vol. unit. H. Moehle found the magnetic susceptibility to be 3.84×10^{-6} mass unit. I. I. Rabi observed with the three planes of symmetry at 27° , $\chi_1=29.6 \times 10^{-6}$, $\chi_2=21.4 \times 10^{-6}$, and $\chi_3=25.7 \times 10^{-6}$ mass unit; and L. C. Jackson, at 17.8° , -232.7° , and 258.22° , respectively, $\chi \times 10^6=24.61$, 241.2 , and 321.6 mass unit—see Fig. 119. Observations were also made by L. C. Jackson and H. K. Onnes. The magneton numbers were also discussed by L. C. Jackson, L. Pauling and M. L. Huggins, and L. C. Jackson and H. K. Onnes. According to G. Quincke, the magnetic susceptibility of an aq. soln. of the salt is 37.2×10^{-6} mass unit at 18° to 20° . Observations were also made by H. Moehle, and B. W. Bartlett. H. E. Armstrong and E. H. Rodd studied the crystallization in a magnetic field. C. von Hauer found that at 20° , a sat. soln. has 14.9 ; at 40° , 20.8 ; at 60° , 25.6 ; and at 80° , 33.0 per cent. of the anhydrous salt; J. Locke observed that at 25° , a litre of water can dissolve 147.2 grms. of the anhydrous salt; and E. Tobler found the solubility, S grms. of anhydrous salt per 100 grms. of water, to be:

	0°	10°	18°	23°	35°	40°	45°	50°	60°	75°
S	8.9	11.6	15.2	17.1	19.6	22.3	25.0	28.7	34.5	43.3

Observations on the solubility were also made by B. Bertisch, and H. T. Kalmus and co-workers. A. Watt described the use of the salt for the electrodeposition of cobalt. S. Miyamoto studied the reduction of the salt by hydrogen in the silent discharge. E. Alberts studied the action of carbon dioxide. G. Spacu and R. Ripan prepared a complex with benzylamine, namely, $[\text{Co}(\text{NH}_2\text{CH}_2.\text{C}_6\text{H}_5)_2(\text{H}_2\text{O})_2] \cdot (\text{NH}_4\text{SO}_4)_2$; and with pyridine, $[\text{Co py}_2(\text{H}_2\text{O})_4](\text{NH}_4\text{SO}_4)_2$.

C. Lepierre and M. Lachaud prepared **ammonium cobalt pentasulphate**, $2(\text{NH}_4)_2\text{SO}_4 \cdot 3\text{CoSO}_4$, by fusing anhydrous cobalt sulphate, or the oxide, hydroxide, or carbonate, with 5 or 6 times its weight of ammonium hydrosulphate. The carmine-red, octahedral, cubic crystals can be rapidly washed with cold water and alcohol. The crystals become hydrated in contact with water. If the salt is heated with ammonium sulphate, it furnishes octahedral crystals of anhydrous cobalt sulphate.

T. Curtius and F. Schrader obtained **hydrazine cobaltous disulphate**, $(\text{N}_2\text{H}_5)_2\text{Co}(\text{SO}_4)_2$, in rose-red, microscopic crystals, by mixing conc. soln. of hydrazine and cobalt sulphates. One part of the salt dissolves in 305.16 parts of water at 12° . When the red, ammoniacal soln. is boiled, it furnishes a red precipitate of $\text{CoSO}_4 \cdot 3\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$. The salt is oxidized by nitric acid, and it is insoluble in hydrochloric acid.

J. L. Proust, and E. Mitscherlich prepared **potassium cobaltous disulphate**, $\text{K}_2\text{Co}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$, from a mixed soln. of the component salts. The red crystals of the *hexahydrate* resemble those of the corresponding potassium magnesium disulphate. F. R. Mallet prepared carmine-red, tetrahedral crystals of the anhydrous salt by fusing a mixture of the component sulphates in theoretical proportions. C. von Hauer obtained very well-developed crystals in the presence of some zinc sulphate. The salt rapidly forms the hexahydrate on exposure to air. O. Aschan, O. Aschan and G. V. Petrelius, and H. Marshall obtained it by the action of a soln. of potassium persulphate on cobalt sulphate. A. Ploin studied solid

soln. of copper and cobalt potassium sulphates. G. Calcagni and D. Marotta studied the f.p. curves of the binary system: $\text{K}_2\text{SO}_4\text{-CoSO}_4$, and the results are summarized in Fig. 123. The compound $\text{K}_2\text{SO}_4\cdot\text{CoSO}_4$ is formed, and decomposes at 560° ; and there is also formed **potassium cobaltous trisulphate**, $\text{K}_2\text{SO}_4\cdot 2\text{CoSO}_4$, which crystallizes at 736° , and has a eutectic at about 725° with 31 per cent. K_2SO_4 . At 735° there is a eutectic corresponding with 60 per cent. K_2SO_4 . There is no sign of the **potassium cobaltous pentasulphate**, $3\text{K}_2\text{SO}_4\cdot 2\text{CoSO}_4$, reported by S. P. Sadtler to be formed in crystals with a definite m.p., when the component salts are fused together in theoretical proportions. This salt was also examined by O. W. Gibbs and F. A. Gent, and A. A. Julien. R. M. Caven and W. Johnston examined the ternary system: $\text{CoSO}_4\text{-K}_2\text{SO}_4\text{-H}_2\text{O}$, at 25° , and expressing the concentrations of sat. soln. in mols of salt per 1000 grms. of water, they obtained the following results (plotted in Fig. 124):

CoSO_4	0	0.150	0.239	0.458	1.095	2.205	2.557	2.536	2.433
K_2SO_4		0.680	0.737	0.780	0.531	0.240	0.212	0.190	0
		K_2SO_4			$\text{K}_2\text{Co}(\text{SO}_4)_2\cdot 6\text{H}_2\text{O}$			$\text{CoSO}_4\cdot 7\text{H}_2\text{O}$	

A. and H. Benrath's study of the ternary system is summarized in Fig. 125. The region of the 1:1:6 double salt is stippled. Co_1 , Co_6 , and Co_7 , respectively, denote the mono-, hexa-, and hepta-hydrates of cobalt sulphate. Observations on the crystals were made by E. Mitscherlich, W. Hofmann, and J. Grailich and

FIG. 123.—The Freezing-point Curves of the System: $\text{K}_2\text{SO}_4\text{-CoSO}_4$.

FIG. 124.—The System: $\text{K}_2\text{SO}_4\text{-CoSO}_4\text{-H}_2\text{O}$, at 25° .

FIG. 125.—The Ternary System: $\text{K}_2\text{SO}_4\text{-CoSO}_4\text{-H}_2\text{O}$.

V. von Lang. C. Montemartini and L. Losana studied the quaternary system: $\text{CoSO}_4\text{-K}_2\text{SO}_4\text{-H}_2\text{SO}_4\text{-H}_2\text{O}$, at temp. between 0° and 25° . The solid phases were CoSO_4 , $\text{CoSO}_4\cdot 6\text{H}_2\text{O}$, $\text{CoSO}_4\cdot 2\text{H}_2\text{O}$, $\text{CoSO}_4\cdot \text{H}_2\text{SO}_4$, $\text{K}_2\text{SO}_4\cdot \text{CoSO}_4\cdot 6\text{H}_2\text{O}$, $\text{KHSO}_4\cdot \text{H}_2\text{O}$, $\text{KHSO}_4\cdot \text{H}_2\text{SO}_4$, and $\text{K}_2\text{SO}_4\cdot \text{KHSO}_4\cdot \text{H}_2\text{O}$.

According to A. E. H. Tutton, the crystals of the hexahydrate, $\text{K}_2\text{Co}(\text{SO}_4)_2\cdot 6\text{H}_2\text{O}$, are prismatic or tabular, monoclinic crystals with the axial ratios $a:b:c = 0.7404:1:0.5037$, and $\beta = 104^\circ 55'$. A. Murmann and L. Rotter gave $0.7327:1:0.4705$, and $\beta = 105^\circ 7'$. There is a cleavage parallel to the $(\bar{2}01)$ -face. The optic axial angles, measured by A. E. H. Tutton, are:

	Li-	C-	Na-	Tl-	F-light
$2E$	$113^\circ 56'$	$114^\circ 0'$	$114^\circ 25'$	$114^\circ 56'$	$115^\circ 40'$
$2H_a$	$61^\circ 4'$	$61^\circ 2'$	$60^\circ 51'$	$60^\circ 40'$	$60^\circ 12'$
$2H_o$	$96^\circ 13'$	$96^\circ 5'$	$95^\circ 40'$	$95^\circ 11'$	$94^\circ 35'$
$2V$	$68^\circ 38'$	$68^\circ 29'$	$68^\circ 41'$	$68^\circ 44'$	$68^\circ 48'$

A rise of temp. increased $2E$ about $2^\circ 15'$ for 50° rise of temp. Observations on the crystals were also made by H. Töpsöe and C. Christiansen; and the formation of solid soln. with the corresponding $K_2SO_4 \cdot CuSO_4 \cdot 6H_2O$, by A. Plöin. H. Schröder gave 3.105 for the sp. gr. of the anhydrous salt; and for the hexahydrate, H. Schiff gave 2.154; R. Krickmeyer, 2.218 at $20^\circ/4^\circ$; O. Pettersson, 2.205 at 16.8° , and 2.214 at 16.6° ; and A. E. H. Tutton, 2.219 at $20^\circ/4^\circ$, 195.68 for the mol. vol., and for the mol. distance ratios, *i.e.* the topic axial angles, $\chi : \psi : \omega = 6.0405 : 8.1583 : 4.1093$. The subject was discussed by J. A. Groshaus. The mol. vol., and the contraction which occurs in the formation of the salt were discussed by F. Ephraim and co-workers, P. Niggli, and O. Pettersson. G. Tammann measured the rate of diffusion of the salt. R. M. Caven and J. Ferguson found the vap. press., p mm., for the hexahydrate to be :

	26.5°	39.6°	45.7°	51.1°	57.0°	60.6°	66.3°	76.3°
p . . .	7.2	19.2	30.6	44.2	64.2	81.6	114.6	201.3

or $\log p = 6.764 - 265.7T^{-1} - 451,350T^{-2}$ for the passage to the dihydrate. The heat of hydration of the dihydrate is 14.0 Cals. per mol of water vapour. R. M. Caven and J. Ferguson gave for the heat of hydration, 520 cal. of liquid water, and at 50° , 14 cal. per mol of water vapour. A. E. H. Tutton gave for the refractive indices of the hexahydrate :

	Li-	C-	Na-	Tl-	F-	G-light
α . . .	1.4780	1.4784	1.4807	1.4830	1.4861	1.4904
β . . .	1.4838	1.4842	1.4865	1.4889	1.4919	1.4961
γ . . .	1.4973	1.4977	1.5004	1.5028	1.5059	1.5105

The mean value for Na-light is 1.4892, and the double refraction $\gamma - \alpha = 0.0197$. H. de Sénarmont gave for the refractive index, 1.465; and C. Schaefer and M. Schubert, for the D -line, $\alpha = 1.4807$, $\beta = 1.4867$, and $\gamma = 1.5004$; and A. Murmann and L. Rotter gave $\beta = 1.482$ for red-light, 1.487 for yellow-light, and 1.490 for green-light. A. E. H. Tutton represented his results by $\beta = 1.4737 + 514824\lambda^{-2} + 1,962,700,000,000\lambda^{-4} + \dots$; and for α , the constant 1.4737 is diminished by 0.0058, and for γ , the constant is increased by 0.0138. The indices of refraction are lowered by about 0.0020 for 50° rise of temp. The optical character is positive. The sp. refractions with the μ^2 -formula, for the C - and G -rays, are, respectively, $\alpha = 0.1282$, and 0.1309; $\beta = 0.1295$, and 0.1322; and $\gamma = 0.1325$, and 0.1354; the mol. refractions, $\alpha = 56.08$, and 57.28; $\beta = 56.66$, and 57.84; and $\gamma = 58.00$, and 59.26; the mol refraction for the C -line with the γ -formula are $\alpha = 94.72$, $\beta = 95.87$, and $\gamma = 98.54$; the sp. dispersions for the G - and C -rays for the μ^2 -formula are $\alpha = \beta = 0.0027$, and $\gamma = 0.0029$; and the mol. dispersions $\alpha = 1.20$, $\beta = 1.18$, and $\gamma = 1.26$. These values are nearly constant for all temp. at which the crystals are stable, because refraction and sp. gr. vary with temp. in the same direction. C. Schaefer and M. Schubert found maxima in the reflection to occur in the ultra-red at 9.03μ and 15.90μ ; and the first maxima in the directions of the three axes are a at 9.10μ ; b at 8.89μ ; and c at 8.76μ . The mol. refractions were discussed by W. J. Pope, E. Widmer, and C. Ehlers; the absorption spectrum, by C. Ehlers; the slight transparency for X-rays, by W. L. Goodwin, and the feeble triboluminescence, by A. Imhof. H. Moehle found the mass susceptibility to be 3.448×10^{-6} vol. unit; and W. Finke gave for the three axial directions, a , b , and c , respectively, 66.59×10^{-6} , 49.62×10^{-6} , and 77.15×10^{-6} vol. unit. I. I. Rabi found for the three planes of symmetry, $\chi_1 = 25.9 \times 10^{-6}$, $\chi_2 = 20.1 \times 10^{-6}$, and $\chi_3 = 21.9 \times 10^{-6}$ mass unit; and L. C. Jackson, and L. C. Jackson and H. K. Onnes gave, respectively, $\chi_1 \times 10^6$, $\chi_2 \times 10^6$, and $\chi_3 \times 10^6$, at 17° , 28.4° , 23.0° , and 24.6° mass unit; at -43° , 37.0° , 27.0° , and 30.1° mass unit; and at -103° , 52.7° , 32.8° , and 38.8° mass unit. Observations were also made by B. W. Bartlett, and N. S. Krishnan and co-workers. The magneton numbers were discussed by B. Cabrera, and L. C. Jackson and H. K. Onnes. H. Baubigny and E. Péchard found that the rate of efflorescence of the crystals in dry air is considerably increased if

the salt is deposited from slightly acidic soln. J. L. Proust noted that the salt is less soluble in water than is cobalt sulphate. C. von Hauer found that a sat. soln. at 20° has 14; at 40°, 19.5; at 60°, 24.4; and at 80°, 31.8 per cent. of anhydrous salt; J. Locke, that a litre of water at 25° dissolves 128.8 grms. of anhydrous salt; and E. Tobler found that the solubility, *S* grms. of the anhydrous salt in 100 grms. of water, is:

	0°	12°	15°	20°	25°	30°	35°	40°	49°
<i>S</i>	19.1	30	32.5	34.9	45.3	51.9	55.4	64.6	81.3

Observations were made by G. J. Mulder, and R. M. Caven and W. Johnston (Fig. 124). R. M. Caven and J. Ferguson observed a dihydrate is formed at 80°, and the anhydrous salt at 95°. G. Spacu prepared complex salts with pyridine, namely, $K_2Co(SO_4)_2 \cdot 3C_5H_5N \cdot 3H_2O$, and $K_2Co(SO_4)_2 \cdot 2C_5H_5N \cdot 4H_2O$. The results of D. Längauer's study on the reciprocal pairs of salts: $CoSO_4 + K_2Cl_2 \rightleftharpoons CoCl_2 + K_2SO_4$, are summarized in Fig. 126.

FIG. 126.—Solid Phases in the Reaction:
 $CoSO_4 + K_2Cl_2 \rightleftharpoons CoCl_2 + K_2SO_4$.

FIG. 127.—The Ternary System:
 $Rb_2SO_4-CoSO_4-H_2O$.

R. Bunsen and G. Kirchhoff prepared **rubidium cobaltous disulphate**, $Rb_2Co(SO_4)_2 \cdot 6H_2O$, from a soln. of the component salts. F. R. Mallet obtained crystals of the anhydrous salt by fusing a mixture of the theoretical proportions of the component salts. A. and H. Benrath's study of the system: $Rb_2SO_4-CoSO_4-H_2O$, is summarized in Fig. 127. The region of the 1:1:6 double salt is stippled, Co_1 , Co_6 , and Co_7 , respectively, refer to the mono-, hexa-, and hepta-hydrates of cobalt sulphate. The ruby-red or reddish-brown crystals of the *hexahydrate* are usually tabular or prismatic, and belong to the monoclinic system having the axial ratios $a:b:c=0.7391:1:0.5011$, and $\beta=106^\circ 1'$. F. L. Perrot gave $0.738986:1:0.494805$, and $\beta=106^\circ 2' 25''$. A. E. H. Tutton observed that the cleavage parallel to the (201)-face is well developed. The crystals are isomorphous with those of the corresponding magnesium, zinc, cadmium, manganous, and nickel salts. The optic axial angles are:

	Li-	C-	Na-	Tl-	F-light
$2E$	129° 46'	129° 51'	130° 10'	130° 29'	130° 55'
$2H_a$	66° 37'	66° 34'	66° 19'	66° 1'	54° 37'
$2H_o$	90° 53'	90° 49'	90° 33'	90° 12'	89° 44'
$2V_a$	75° 15'	75° 14'	75° 11'	75° 8'	75° 3'

The optical axial angle $2E$ increases about 2° for every 50° rise of temp. F. L. Perrot gave 2.56 for the sp. gr., and A. E. H. Tutton, 2.567 at $20^\circ/4^\circ$, and mol. vol. 205.03. The mol. distance ratios, i.e. the topic axial ratios, $\chi:\psi:\omega=6.1494:8.3201:4.1692$. The mol. vol. and the vol. contraction were studied by F. Ephraim and co-workers, and P. Niggli. R. M. Caven and C. J. Ferguson found the vap. press., *p* mm., of the hexahydrate to be:

	28.4°	33.3°	38.4°	45.3°	52.6°	58.9°	65.1°	76.1°
<i>p</i>	4.3	6.8	9.7	16.3	26.9	41.7	59.9	112.2

or $\log p = 3.740 + 1594T^{-1} - 762,740T^{-2}$ for the passage to the dihydrate. The heat of hydration of the dihydrate is 14.3 Cals. per mol of water vapour. According to A. E. H. Tutton, the refractive indices are :

	Li-	C-	Na-	Tl-	F-	G-light
α . . .	1.4833	1.4837	1.4859	1.4882	1.4910	1.4954
β . . .	1.4889	1.4893	1.4916	1.4940	1.4968	1.5011
γ . . .	1.4985	1.4989	1.5014	1.5038	1.5068	1.5114

The mean value for Na-light is 1.4962, and the double refraction $\gamma - \alpha = 0.0130$. The optical character is positive. Observations were made by F. L. Perrot, and W. J. Pope. F. L. Perrot gave $\alpha = 1.50123$, $\beta = 1.49165$, and $\gamma = 1.48596$ for the *D*-line. A. E. H. Tutton found that the index $\beta = 1.4789 + 507,763\lambda^{-2} + 1,841,600,000,000\lambda^{-4} + \dots$. The α indices can be represented by this formula if 1.4789 be lowered by 0.0057; and the γ indices if the constant 1.4789 be raised by 0.0098. The refractive indices are lowered by about 0.0016 for 50° rise of temp. The sp. refractions with the μ^{-2} -formula for the *C*- and *G*-rays are, respectively, $\alpha = 0.1119$, and 0.1142; $\beta = 0.1130$, and 0.1153; and $\gamma = 0.1149$, and 0.1173; and the mol. refractions, $\alpha = 59.31$, and 60.53, $\beta = 59.90$, and 61.12, and $\gamma = 60.89$, and 62.18. The corresponding sp. dispersions for the *G*- and *C*-rays are $\alpha = \beta = 0.0023$, and $\gamma = 0.0024$; and the mol. dispersions, $\alpha = \beta = 1.22$, and $\gamma = 1.29$. The mol. refractions by the μ -formula, and the *C*-line, are $\alpha = 100.34$, $\beta = 101.50$, and $\gamma = 103.49$. A. A. Lutheroth studied the magnetic properties of the crystals. I. I. Rabi observed that for the three planes of symmetry, the magnetic susceptibility, at 27°, are $\chi_1 = 22.0 \times 10^{-6}$, $\chi_2 = 16.7 \times 10^{-6}$, and $\chi_3 = 19.1 \times 10^{-6}$ mass unit; and L. C. Jackson and H. K. Onnes found the values of $\chi \times 10^6$ at 25°, -195.6°, and -258.34°, are, respectively, 20.98, 65.06, and 268.0 mass unit. The magneton numbers were discussed by B. Cabrera, and L. C. Jackson and H. K. Onnes. J. Locke found that a litre of water, at 25°, dissolves 92.8 grms. of the anhydrous salt. Observations were made by E. Biron.

R. Bunsen and G. Kirchhoff prepared **cæsium cobaltous disulphate**, $\text{Cs}_2\text{Co}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$, from a soln. of the component salts; and F. R. Mallet obtained crystals of the anhydrous salt by fusing a mixture of the theoretical proportions of the component salts. The brownish-red crystals of the *hexahydrate* are prismatic, and, according to A. E. H. Tutton, they belong to the monoclinic system, and have the axial ratios $a : b : c = 0.7270 : 1 : 0.4968$, and $\beta = 107^\circ 8'$. The cleavage parallel to the (201)-face is well developed. The optic axial angle $2E$ is very large, for the Na-light the angle is probably near $156^\circ 40'$; the other optic axial angles are, for :

	Li-	C-	Na-	Tl-	F-light
$2H_a$. . .	$73^\circ 29'$	$73^\circ 12'$	$73^\circ 7'$	$72^\circ 48'$	$72^\circ 25'$
$2H_o$. . .	$87^\circ 34'$	$87^\circ 30'$	$87^\circ 19'$	$87^\circ 9'$	$86^\circ 49'$
$2V_a$. . .	$81^\circ 42'$	$81^\circ 40'$	$81^\circ 34'$	$81^\circ 29'$	$81^\circ 22'$

The sp. gr. is 2.844 at 20°/4°; the mol. vol., 218.11; and the mol. distance ratios, i.e. the topic axial ratios, are $\chi : \psi : \omega = 6.2386 : 8.5814 : 4.2632$. The mol. vol., and the vol. contraction were studied by F. Ephraim and co-workers, and P. Niggli. R. M. Caven and J. Ferguson found the vap. press., p mm., of the hexahydrate to be :

	29.2°	41.0°	47.0°	53.8°	60.2°	75.0°
p . . .	5.1	12.2	19.6	31.3	47.6	118.6

or $\log p = 8.164 - 1221T^{-1} - 313,270T^{-2}$, for the passage to the dihydrate. The heat of hydration of the dihydrate is 14.4 Cals. per mol. of water vapour. According to A. E. H. Tutton, the indices of refraction are :

	Li-	C-	Na-	Tl-	F-	G-light
α . . .	1.5028	1.5032	1.5037	1.5079	1.5112	1.5159
β . . .	1.5057	1.5061	1.5085	1.5110	1.5142	1.5188
γ . . .	1.5102	1.5106	1.5132	1.5156	1.5187	1.5237

The mean value for Na-light is 1.5091, and the double refraction $\gamma - \alpha = 0.0075$. The optical character is positive. The values for β can be represented by

$\beta = 1.4952 + 532,337\lambda^{-2} + 1,971,500,000,000\lambda^{-4} + \dots$. The α indices are closely reproduced if the constant 1.4952 is diminished by 0.0029, and the γ indices if that constant is increased by 0.0046. The refractive indices are lowered 0.0018 by a rise of temp. of 50° . The sp. refractions with the μ^2 -formula for the C - and G -rays are, respectively, $\alpha = 0.1043$, and 0.1065 ; $\beta = 0.1048$, and 0.1070 ; and $\gamma = 0.1056$, and 0.1079 ; the mol. refractions, $\alpha = 65.19$, and 66.57 ; $\beta = 65.51$, and 66.89 ; and $\gamma = 66.00$, and 67.41 ; the sp. dispersions, $\alpha = \beta = 0.0022$, and $\gamma = 0.0023$; and the mol. dispersions, $\alpha = \beta = 1.38$, and $\gamma = 1.41$. The mol. refractions with the μ -formula are $\alpha = 110.95$, $\beta = 111.58$, and $\gamma = 112.57$. Observations on the subject were made by W. J. Pope, and E. Widmer. J. Locke found that a litre of water at 25° dissolves 418.8 grms. of the anhydrous salt. The subject was studied by E. Biron.

C. F. Rammelsberg was unable to prepare **lithium cobaltous sulphate**; and G. Calcagni and D. Marotta observed no sign of such a compound on the f.p. curves of the binary system: Li_2SO_4 - CoSO_4 . There is a limited field of solid soln. from about 100 to 83 per cent. of Li_2SO_4 , and there is a eutectic at 595° and 63 per

FIG. 128.—Freezing-point Curves of the System: Li_2SO_4 - CoSO_4 .

FIGS. 129 and 130.—Mutual Solubilities of Sodium and Cobaltous Sulphates.

cent. Li_2SO_4 . J. Koppel and H. Wetzel, and H. Wetzel prepared pale red **sodium cobaltous disulphate**, $\text{Na}_2\text{Co}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$, by melting together eq. proportions of the hydrated salts at 25° ; and their observations on the system: Na_2SO_4 - CoSO_4 - H_2O are summarized in Figs. 129 and 130. Corresponding soln. are designed with similar letters in both diagrams, those without the dash refer to cobalt sulphate, and those with the dash to sodium sulphate. The curves FG and $F'G'$ refer to the solubilities of mixtures of the component sulphates; GJ and $G'J'$, to the solubility of the complex salt $\text{Na}_2\text{Co}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$; GH and $G'H'$, to that of a mixture of the complex salt and cobalt sulphate; GKL and $G'K'L'$, to that of a mixture of the complex salt and sodium sulphate; OAB , to the solubility of cobalt sulphate; $OCDE$, to the solubility of cobalt sulphate; A , to the eutectic $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$ and ice; and C , to the eutectic $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ and ice. The temp. of formation of the complex salt is 17.5° ; the transformation temp. of decahydrated sodium sulphate in the presence of cobalt sulphate, is 31.5° ; and the eutectic with a mixture of the two hydrated sulphates is -4.5° . A. and H. Benrath examined the ternary system at 97° , and the following is a selection of their results for soln. in which the proportions of sodium and cobalt sulphates are expressed in percentages by weight; x denotes the mol. proportion of CoSO_4 in the mixture, and M , the number of mols of water per mol. of salt:

CoSO_4	0	4.80	6.38	9.21	24.07	28.13	28.91	31.21	34.33
Na_2SO_4	3.50	28.08	27.64	24.89	11.76	10.34	9.01	2.96	—
x	0	13.52	17.48	25.32	65.24	74.40	74.60	90.55	100.00
M	15.56	16.32	15.56	15.62	14.97	13.43	13.79	16.45	16.4
	Na_2SO_4		$\text{Na}_2\text{Co}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$				$\text{CoSO}_4 \cdot \text{H}_2\text{O}$		

The results are plotted in Fig. 131; the dotted line refers to the sp. gr. of the soln. A. and H. Benrath's results at different temp. are summarized in Figs. 131 and 132. R. M. Caven and W. K. Gardner also studied the subject.

FIG. 131.—Equilibrium in the Ternary System: Na_2SO_4 — CoSO_4 — H_2O , at 97° .

FIG. 132.—The Ternary System: Na_2SO_4 — CoSO_4 — H_2O .

O. Aschan reported the formation of crystals of **sodium cobalt disulphate**, $\text{Na}_2\text{SO}_4 \cdot \text{CoSO}_4 \cdot 6\text{H}_2\text{O}$, by the action of cobalt turnings on a soln. of sodium persulphate; and M. Wikul, of crystals of **sodium hydrodisulphate**, $\text{NaHSO}_4 \cdot (\text{CoO})_2\text{SO}_4 \cdot 9\text{H}_2\text{O}$, by the action of a soln. of cobalt nitrate and sodium sulphate in conc. sulphuric acid. The water of hydration is expelled at 130° . G. Calcagni and D. Marotta observed that fused mixtures of sodium and cobaltous sulphates form a compound **sodium cobaltous tetrasulphate**, $3\text{Na}_2\text{SO}_4 \cdot \text{CoSO}_4$, Fig. 134, and it decomposes above 425° . Solid

FIG. 133.—The Ternary System: Na_2SO_4 — NiSO_4 — H_2O .

FIG. 134.—Freezing-point Curves of the Ternary System: Na_2SO_4 — CoSO_4 .

soln. are formed when 100 to 67 per cent. of Na_2SO_4 are present, and there is a eutectic at 575° when 50 per cent. of either component is present.

J. von Liebig described what he regarded as a **copper cobaltous sulphate**, $\text{CuSO}_4 \cdot 2\text{CoSO}_4 \cdot 30\text{H}_2\text{O}$, in monoclinic prisms resembling heptahydrated ferrous sulphate, dark green in reflected light, and rose-red in transmitted light. There was here an error in the determination of the water of crystallization, since C. von Hauer showed that the product is $\text{CuSO}_4 \cdot 2\text{CoSO}_4 \cdot 21\text{H}_2\text{O}$. He obtained this salt by the spontaneous evaporation of a soln. of cobalt sulphate in a sat. soln. of copper sulphate. The crystals are stable in air. A. Brezina showed that the crystals here are triclinic, like those of pentahydrated copper sulphate. A. Scott obtained crystals of the trihydrate, $\text{CuSO}_4 \cdot 2\text{CoSO}_4 \cdot 3\text{H}_2\text{O}$, in rose-red crystals, from a mixed

soln. of the component sulphate containing about 90 grms. of hydrated copper sulphate, 100 grms. of hydrated cobalt sulphate, 200 c.c. water, and then adding 130 c.c. of conc. sulphuric acid. It is probable that these products are solid soln. of copper and cobalt sulphates. E. Mitscherlich, A. Arzruni, E. Wohlwill, and J. W. Retgers observed that mixed soln. of the two salts furnish red, monoclinic crystals if the cobalt sulphate is in excess, and blue, triclinic crystals if the sulphate is in excess. H. D. Crockford and D. J. Brawley investigated the phases in the ternary system: $\text{CuSO}_4\text{--CoSO}_4\text{--H}_2\text{O}$ at 0° and at 25° . The results at 25° are summarized in Fig. 135. The results at 0° and at 25° indicate the presence of pentahydrated copper sulphate, and of a series of solid soln. in which copper partially replaces cobalt in heptahydrated cobalt sulphate. The crystals of isomorphous mixtures or solid soln. of the two salts, $(\text{Cu},\text{Co})\text{SO}_4\cdot 7\text{H}_2\text{O}$, were measured by B. Bertisch, H. Dufet, A. Ploin, L. de Boisbaudran, and E. Jannettaz. According to G. Brügellmann, when equal vols. of cold, sat. soln. of copper sulphate and cobalt chloride are mixed, and allowed to evaporate spontaneously, crystals containing sulphates of cobalt and copper were obtained, and chlorides of both metals remained in soln. W. Finke found the magnetic susceptibility of copper cobaltous sulphate, $\text{CoSO}_4\cdot\text{CuSO}_4\cdot 6\text{H}_2\text{O}$, to range from 23.75×10^{-6} to 28.56×10^{-6} mass unit. W. Finke

gave for the magnetic susceptibilities of $\text{CoSO}_4 + \text{CuSO}_4 + 6\text{H}_2\text{O}$ in the three axial directions, a , b , and c , respectively, 28.62×10^{-6} , 23.06×10^{-6} , and 25.57×10^{-6} mass unit. A. Étard obtained rose-red crystals of **copper cobaltous hydrosulphate**, $2\text{CuSO}_4\cdot 2\text{CoSO}_4\cdot \text{H}_2\text{SO}_4$, by heating a sat. soln. of the constituent salts with a large excess of conc. sulphuric acid, in a sealed tube, at 200° . G. Spacu and R. Ripan reported a complex salt with benzylamine, namely, $2\text{CoSO}_4\cdot \text{CuSO}_4\cdot 6\text{C}_7\text{H}_7(\text{NH}_2)\cdot 6\text{H}_2\text{O}$; and one with pyridine, $2\text{CoSO}_4\cdot \text{CuSO}_4\cdot 7\text{C}_6\text{H}_5\text{N}\cdot 5\text{H}_2\text{O}$. H. Vohl obtained violet-red crystals of **ammonium copper cobaltous sulphate**, $2(\text{NH}_4)_2\text{SO}_4\cdot \text{CuSO}_4\cdot \text{CoSO}_4\cdot 12\text{H}_2\text{O}$; and likewise also **potassium copper cobaltous sulphate**, $2\text{K}_2\text{SO}_4\cdot \text{CuSO}_4\cdot \text{CoSO}_4\cdot 12\text{H}_2\text{O}$, but E. Aston and S. U. Pickering could not

establish the chemical individuality of these products, since they have the character of solid soln. A. Ploin studied the solid soln. of the potassium salt, and B. Bertisch, of the ammonium salt with the copper salt. A. Mailhe prepared **copper cobaltous trioxydisulphate**, $2\text{CoSO}_4\cdot 3\text{CuO}\cdot 12\text{H}_2\text{O}$, or, according to A. Werner, $\text{Cu}_2(\text{OH})_4\text{Cu}=(\text{OH})_2\text{Co}(\text{SO}_4)_2\text{Co}\cdot 7\text{H}_2\text{O}$, by the action of a cold soln. of 1 to 0.5 mol of CoSO_4 per litre on $4\text{CuO}\cdot \text{H}_2\text{O}$. The salt is isomorphous with the corresponding salt of nickel. It occurs in chestnut-brown, hexagonal plates. If the soln. of copper sulphate has 0.25 mol per litre, crystals of **copper cobaltous dioxysulphate**, $2\text{CuO}\cdot \text{CoSO}_4\cdot 6\text{H}_2\text{O}$, are formed, and they are isomorphous with the corresponding nickel salt. W. A. Endriss made some observations on this subject. A. Recoura reported the basic salts, $\text{CoSO}_4\cdot 3\text{CuO}\cdot n\text{H}_2\text{O}$, to be formed by the action of a boiling, aq. soln. of cobalt sulphate on cupric hydroxide; and $\text{CoSO}_4\cdot 24\text{CuO}\cdot n\text{H}_2\text{O}$, from cupric hydroxide and a cold, aq. soln. of cobalt sulphate.

P. C. Ray and P. B. Sarkar, and P. B. Sarkar and N. Ray prepared **potassium cobaltous sulphatofluoberyllate**, $\text{CoSO}_4\cdot \text{K}_2\text{BeF}_4\cdot 6\text{H}_2\text{O}$, and **ammonium cobaltous sulphatofluoberyllate**, $\text{CoSO}_4\cdot (\text{NH}_4)_2\text{BeF}_4\cdot 6\text{H}_2\text{O}$, by crystallization from soln. of cobaltous sulphate and potassium or ammonium fluoberyllate.

G. C. Winkelblech obtained crystals of **magnesium cobaltous sulphate**, $\text{MgSO}_4\cdot 3\text{CoSO}_4\cdot 28\text{H}_2\text{O}$, from a soln. of the constituent salts; and H. Vohl reported **ammonium magnesium cobaltous sulphate**, $2(\text{NH}_4)_2\text{SO}_4\cdot \text{MgSO}_4\cdot \text{CoSO}_4\cdot 12\text{H}_2\text{O}$;

FIG. 135.—The Ternary System : $\text{CuSO}_4\text{--CoSO}_4\text{--H}_2\text{O}$, at 25° .

and **potassium magnesium cobaltous sulphate**, $2K_2SO_4 \cdot MgSO_4 \cdot CoSO_4 \cdot 12H_2O$, to be formed from soln. of the component salts, but E. Aston and S. U. Pickering could not establish the chemical individuality of these products, and they regarded them as solid soln. G. Spacu and R. Ripan reported complex salts with benzylamine, $2CoSO_4 \cdot MgSO_4 \cdot 5C_7H_7(NH_2) \cdot 7H_2O$; and with pyridine, $2CoSO_4 \cdot MgSO_4 \cdot 7C_5H_5N \cdot 5H_2O$. D. Link reported that mixed soln. of cobalt and zinc sulphates furnished red, four-sided prisms of **zinc cobaltous sulphate**, which, on exposure to air, crumble to a white powder. H. Bassett and I. Sanderson examined the cadmium-cobaltous-sulphate system at 25° and 80° , but no definite compound of the two sulphates was observed. S. Meyer studied the crystallization of the salt in a magnetic field. H. Vohl reported **ammonium zinc cobaltous sulphate**, $2(NH_4)_2SO_4 \cdot ZnSO_4 \cdot CoSO_4 \cdot 12H_2O$, and **potassium zinc cobaltous sulphate**, $2K_2SO_4 \cdot ZnSO_4 \cdot CoSO_4 \cdot 12H_2O$, from soln. of the component salts. It is probable that these products are solid soln.

FIG. 136.—The Ternary System:
 $Ti_2SO_4-CoSO_4-H_2O$.

O. Pettersson prepared ruby-red, prismatic crystals of **thallous cobaltous disulphate**, $Tl_2Co(SO_4)_2 \cdot 6H_2O$, from a mixed soln. of the component salts. The system $CoSO_4-Tl_2SO_4-H_2O$ was studied by A. and H. Benrath, H. Weiland, and H. Hamacher. A. and H. Benrath's results are summarized in Fig. 136, where the region of the 1 : 1 : 6 double salt is stippled. Co_1 , Co_6 , and Co_7 , respectively, refer to the mono-, hexa-, and the hepta-hydrates of cobalt sulphate. F. R. Mallet prepared crystals of the anhydrous salt by fusing mixtures of the com-

to A. E. H. Tutton, the crystals of the *hexahydrate* belong to the monoclinic system, and have the axial ratios $a : b : c = 0.7413 : 1 : 0.4995$, and $\beta = 106^\circ 25'$. The cleavage parallel to the (201) -face is well developed; and that parallel to the (010) -face is feeble. The optic axial angles are :

	Li-	C-	Na-	Tl-	F-light
$2E$	$122^\circ 49'$	$123^\circ 13'$	$125^\circ 31'$	$127^\circ 27'$	—
$2H_a$	$63^\circ 45'$	$63^\circ 46'$	$64^\circ 2'$	$64^\circ 12'$	—
$2H_o$	$108^\circ 39'$	$108^\circ 33'$	$107^\circ 30'$	$106^\circ 24'$	—
$2I_a$	$66^\circ 3'$	$66^\circ 7'$	$66^\circ 39'$	$67^\circ 8'$	$68^\circ 0'$

O. Pettersson gave for the sp. gr. 3.729 at 16.2° to 3.803 at 16.4° ; and A. E. H. Tutton, 3.782 at $20^\circ/4$; the mol. vol., 201.40; and the mol. distance ratios, *i.e.* the topic axial ratios, are $\chi : \psi : \omega = 6.1356 : 8.2769 : 4.1344$. The refractive indices are :

	Li-	C-	Na-	Tl-	F-	G-light
α	1.5959	1.5965	1.6009	1.6061	1.6121	1.6197
β	1.6122	1.6128	1.6176	1.6231	1.6293	1.6369
γ	1.6182	1.6188	1.6238	1.6294	1.6359	1.6435

The mean refractive index for Na-light is 1.6141; and the double refraction $\gamma - \alpha = 0.6229$. The general formula for β is $\beta = 1.5951 + 714.173\lambda^{-2} + 2,804,900,000\lambda^{-4} + \dots$. The index α is reproduced if the constant 1.5951 is diminished by 0.0167, and the index γ , if it is increased by 0.0062. The sp. refractions with the μ^2 -formula for the $C(H_a)$ - and the H_γ (near G)-rays are, respectively, $\alpha = 0.0900$, and 0.0928 ; $\beta = 0.0920$, and 0.0949 ; and $\gamma = 0.0927$, and 0.0957 ; and the mol. refractions, $\alpha = 68.57$, and 70.72 ; $\beta = 70.08$, and 72.28 ; and $\gamma = 70.63$, and 72.88 ; the sp. dispersions for G - and C -rays, $\alpha = 0.0028$, $\beta = 0.0029$, and $\gamma = 0.0030$; and the mol. dispersions, $\alpha = 2.15$, $\beta = 2.20$, and $\gamma = 2.25$. The mol. dispersions by the μ -formula are $\alpha = 120.13$, $\beta = 123.42$, and $\gamma = 124.62$, mean 122.72.

H. Vohl reported crystals of **ammonium manganous cobaltous sulphate**,

$2(\text{NH}_4)_2\text{SO}_4 \cdot \text{MnSO}_4 \cdot \text{CoSO}_4 \cdot 12\text{H}_2\text{O}$, and of **potassium manganous cobaltous sulphate**, $2\text{K}_2\text{SO}_4 \cdot \text{CoSO}_4 \cdot 12\text{H}_2\text{O}$, to be formed from mixed soln. of the component salts. What evidence is available with other salts favours the assumption that these products are solid soln. J. W. Retgers investigated the complete series of solid soln. formed with the heptahydrated cobaltous and ferrous sulphates; and there is no sign of the formation of a **ferrous cobaltous sulphate**. A. Étard reported **ferrous cobaltous hydrosulphate**, $2\text{FeSO}_4 \cdot 2\text{CoSO}_4 \cdot \text{H}_2\text{SO}_4$, to be formed by treating a sat. soln. of the component salts with a large excess of cold sulphuric acid. B. Gossner and M. Arm reported, $\text{K}_2\text{H}_{10}(\text{SO}_4)_6 \cdot 3\text{Fe}(\text{OH})_3 \cdot 4\text{CoSO}_4 \cdot 4\text{H}_2\text{O}$. H. G. K. Westenbrink observed that the introduction of cobalt sulphate in ferrous sulphate has very little influence on the space-lattice of ferrous sulphate. H. Vohl reported **ammonium ferrous cobaltous sulphate**, $2(\text{NH}_4)_2\text{SO}_4 \cdot \text{FeSO}_4 \cdot \text{CoSO}_4 \cdot 12\text{H}_2\text{O}$, and **potassium ferrous cobaltous sulphate**, $2\text{K}_2\text{SO}_4 \cdot \text{FeSO}_4 \cdot \text{CoSO}_4 \cdot 12\text{H}_2\text{O}$, but these products may be solid soln.

J. G. Gentile³ found that a conc. soln. of cobaltous sulphate gives a green precipitate of **cobaltous oxysulphate**, $\text{Co}_2\text{O}_3 \cdot 6\text{CoSO}_4 \cdot 15\text{H}_2\text{O}$, when treated with conc. aq. ammonia, and the precipitate gradually passes into soln. Water re-precipitates a similar product.

P. C. Ray and P. B. Sarkar⁴ prepared monoclinic crystals of **ammonium cobalt sulphatofluoberyllate**, $(\text{NH}_4)_2\text{BeF}_4 \cdot \text{CoSO}_4 \cdot 6\text{H}_2\text{O}$, and of **potassium cobalt sulphatofluoberyllate**, $\text{K}_2\text{BeF}_4 \cdot \text{CoSO}_4 \cdot 6\text{H}_2\text{O}$, in isomorphous series with Ni, Fe, Mn, Cd, Zn, and Mg in place of Co. H. Siefert studied the crystals.

§ 24. Cobaltic Sulphate and its Complex Salts

H. Marshall¹ prepared hydrated cobaltic sulphate, $\text{Co}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$, by the electrolysis of a sat. soln. of cobaltous sulphate in dil. sulphuric acid (1 : 8) in a platinum dish as anode, and as cathode, a piece of platinum wire in a porous cell containing dil. sulphuric acid. E. Oberer, H. Copaux, and S. Swann and T. S. Xanthakos also prepared this salt electrolytically. E. Oberer studied the

theory of the process. Other things being equal, increasing the concentration of the acid in the electrolyte from $\frac{1}{3}N$ - to $5N$ - H_2SO_4 , raised the proportion of $Co^{+++} : Co^{++}$ from 0.26 : 1 to 2.72 : 1; increasing the concentration of the cobaltous salt from 0.005 to 0.133 gram-atom lowered the proportion of $Co^{+++} : Co^{++}$ from 5.43 : 1 to 3.45 : 1; lowering the temp. from 30° to -7° , raised the proportion $Co^{+++} : Co^{++}$ from 0.24 : 1 to 7.22 : 1; and raising the current density from 0.5 amp. to 1 amp. to 2 amp., altered the ratio $Co^{+++} : Co^{++}$ from 1.48 : 1 to 1.77 : 1 to 1.18 : 1. The potential of the cobaltous-cobaltic sulphate soln. referred to the normal hydrogen electrode, was studied by A. B. Lamb and A. T. Larson. E. Oberer found that in the presence of $2N$ - H_2SO_4 , for soln. with C grms. of the salts in 50 c.c. of water :

Co^{+++}	0.102	0.103	0.287
Co^{++}	1.372	0.171	0.260
Maximum potential	-1.705	-1.741	-1.759 volts

H. Marshall observed that cobaltic sulphate collects about the anode in a dry atmosphere, or if gently warmed, it loses water, and rapidly decomposes, becoming first of a brownish colour, which quickly gives place to pink. If kept in a moderately moist atmosphere, this does not take place nearly so readily; some which has been kept in a tightly-stoppered tube for months does not show any signs of decomposition. Treated with water, it dissolves, but immediately begins to decompose, becoming of a dark purplish colour, quickly changing to a greyish, neutral tint, and ultimately becoming pink. The oxygen liberated is evolved briskly during the process. The greyish tint seems to indicate that the colours of the cobaltous and cobaltic salts are nearly complementary. S. R. Benedict obtained what he regarded as a soln. of nickelic sulphate, by digesting nickelic oxide with a nearly sat. soln. of potassium hydrosulphate, but not so with cobaltic sulphate. A. Mailfert noted the formation of a brown precipitate when ozone acts on a feebly acidic soln. of cobalt sulphate, and P. Jannasch and W. Gottschalk regarded the precipitate as hydrated cobaltic oxide. E. Brunner, and S. Jahn discussed the formation of a soln. of cobaltic sulphate by the action of ozonized oxygen on a soln. of cobalt sulphate. The formation of the crystals by oxidizing a soln. of cobalt sulphate with fluorine, was described by F. Fichter and co-workers, E. Oberer, N. C. Jones, and W. D. Bancroft and N. C. Jones. H. Wolfmann obtained cobaltic sulphate by the action of fluorine on a sulphuric acid soln. of cobaltous fluoride :

A soln. of 2.4 grms. of heptahydrated cobaltous fluoride in 1.5 c.c. of $8N$ - H_2SO_4 , at 30° , was treated with fluorine whilst the soln. was slowly cooling to 0° . The soln. becomes brown, then green, and then acicular crystals, with a silky lustre, are formed. In about $1\frac{1}{2}$ hrs., the platinum crucible contains bluish-green crystals of cobaltic sulphate; and there is a risk of choking the inner tube by the formation of these crystals.

J. Topp observed two bands at $612m\mu$ and $400m\mu$ in the absorption spectrum in the visible region; and a band at $300m\mu$ in the ultra-violet. E. Miescher also studied the absorption spectrum. E. Oberer studied the decomposition of the green, aq. soln. of cobaltic sulphate whereby oxygen is developed and cobaltous sulphate is formed, by a reaction which is symbolized : $Co_2(SO_4)_3 + H_2O = 2CoSO_4 + H_2SO_4 + O$. The velocity constants, k_1 and k_2 , on the assumption that the reaction is, respectively, of the first and second orders, are :

Time	.	15	60	120	180	240	345 mins.
k_1	.	0.00201	0.00188	0.00192	0.00179	0.00163	0.00132
k_2	.	0.00119	0.00132	0.00152	0.00164	0.00164	0.00144

Neither of the results for k_1 and k_2 is conclusive, but it is thought that they agree best with the assumption that the reaction is of the first order, and that it is retarded by the increasing concentration of the acid produced in the reaction. The electrode potential of soln. in $2N$ - H_2SO_4 , with platinum electrodes at 0° , is 1.759 volt for a soln. with 0.287 gm. Co^{+++} and 0.260 gm. Co^{++} in 50 c.c. R. H. Weber found the mol. magnetic susceptibility to be 4860×10^{-6} mass unit.

H. Marshall observed that cobaltic sulphate dissolves very easily, and without

immediate decomposition, in dil. sulphuric acid. Such a soln. is greenish-blue, but gradually decomposes completely in the course of a day or two. It is, of course, very easily decomposed by all reducing agents. It gives a black precipitate when alkali is quickly added. The solid is also soluble in conc. acetic and nitric acids. Conc. sulphuric acid dissolves it, with formation of a deep reddish-brown solution. With hydrochloric acid, cobaltous salt and chlorine are formed. In agreement with H. Marshall, H. Wolfmann observed that ice-cold water rapidly decomposes the salt, and with warm water, the decomposition is instantaneous: $\text{Co}_2(\text{SO}_4)_3 + \text{H}_2\text{O} = 2\text{CoSO}_4 + \text{H}_2\text{SO}_4 + \text{O}$. M. Wikul prepared a salt corresponding with **cobaltyl sulphate**, $(\text{CoO})_2\text{SO}_4$. S. Jahn found that ozone decomposes the soln. until a state of equilibrium is attained: $\text{Co}^{+++} \rightleftharpoons \text{Co}^{++}$. E. Oberer found that the decomposition of the aq. soln. is accelerated by the catalytic action of finely-divided platinum, and by the addition of cobaltous sulphate. H. Marshall, F. Fichter and H. Wolfmann, and E. Brunner observed that soda-lye gives a black precipitate; hydrochloric acid dissolves the salt, forming a blue soln. which gives off chlorine; with potassium iodide, iodine is liberated; dil. sulphuric acid forms a green soln. in the cold, which decomposes when warmed; conc. sulphuric acid forms a reddish-brown soln.; conc. nitric acid forms a green soln., which becomes red when warmed; dil. nitric acid immediately decomposes the salt; acetic acid forms a green soln.; glycerol forms a rose-red soln.; ethyl alcohol immediately decomposes the salt—H. Copaux added that the alcohol is oxidized to aldehyde; and the salt is insoluble in ether and in carbon disulphide, and both liquids rapidly decompose the salt. A. Naumann and J. Schröder said that the sulphate is insoluble in pyridine.

H. Marshall, and E. Oberer prepared **ammonium cobaltic disulphate**, $\text{NH}_4\text{Co}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$, or *cobaltic alum*, $(\text{NH}_4)_2\text{SO}_4 \cdot \text{Co}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$. H. Marshall said: The sulphate was electrolyzed till a large quantity of cobaltic salt had separated. The temp. was then allowed to rise to about 20° , and dil. acid added to dissolve the solid which still remained. The roughly-calculated quantity of ammonium sulphate in fine powder was now added (only a small proportion of the cobalt passes to the inner cell) and a weak current passed until this was practically all dissolved. The clear liquid was then decanted and cooled by a freezing mixture. In this way a large crop of minute, octahedral crystals of the alum was obtained. By more slowly cooling, larger crystals, recognizable with the naked eye, or easily with a hand-lens, separated; they had a fine, deep blue colour. That they were regular octahedra was shown by their behaviour in polarized light. F. Müller observed that the vap. press. of the salt, p mm., is 6.5 at 15° , 40 at 28° , and 91 at $35\text{--}5^\circ$. H. Marshall, and E. Oberer prepared **potassium cobaltic disulphate**, $\text{KCo}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$, by the method employed for the ammonium salt; and H. Copaux, by mixing eq. proportions of well-cooled soln. of the component salts, and washing the crystalline precipitate, first with acetic acid, and then with acetone. H. Marshall added that the alums behave towards water and acids like the cobaltic sulphate. They also decompose when they lose water. The crystals cannot be completely freed from mother-liquor by a porous plate, but may subsequently be pressed between filter-paper, with which, however, they must not be left long in contact.

J. L. Howe and E. A. O'Neal, and E. Oberer prepared **rubidium cobaltic disulphate**, $\text{RbCo}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$, by electrolyzing a soln. of the component sulphates acidified with sulphuric acid; and H. Copaux, by mixing soln. of the component sulphates as in the case of the potassium salt. The deep blue, octahedral crystals are stable in dry air, but decompose in moist air. J. Locke found the m.p. to be 47° . In water, oxygen and cobaltous sulphate are formed; blue soln. are formed with dil. hydrochloric or sulphuric acid, and decomposition, with the formation of a brown soln., occurs in the presence of conc. hydrochloric or sulphuric acid. J. L. Howe and E. A. O'Neal, and E. Oberer also prepared pale greenish-blue crystals of **cæsium cobaltic disulphate**, $\text{CsCo}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$, in a similar manner. J. Locke found the m.p. to be 63° . F. Ephraim and P. Wagner found the vap.

press. to be 4 mm. at 27°, and 25 mm. at 39°; whilst above 40°, the salt decomposes, with the evolution of oxygen, and the green crystals become rose-red. J. Locke found that a litre of water at 25°, dissolves 418.8 grms. of the anhydrous salt. J. L. Howe and E. A. O'Neal said that the salt is readily decomposed by water, with the evolution of oxygen, and that the behaviour of the salt towards dil. and conc. hydrochloric and sulphuric acids resembles that of the rubidium salt. M. Wikul prepared **sodium cobaltyl sulphate**, $(\text{CoO})_2\text{SO}_4 \cdot \text{NaHSO}_4$.

The CoA_6 or Hexammine Family

E. Frémy,² J. G. Gentile, and O. W. Gibbs and F. A. Genth prepared **cobaltic hexamminosulphate**, $[\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3 \cdot 5\text{H}_2\text{O}$, by oxidizing an ammoniacal soln. of a mixture of cobaltous sulphate and chloride with air, and digesting the product with a soln. of silver sulphate in dil. sulphuric acid; or by treating the aquopentamminosulphate with aq. ammonia. L. Jacobsen used lead dioxide as oxidizing agent with an ammoniacal soln. of ammonium cobaltous sulphate; and S. M. Jörgensen saturated the corresponding chloride with freshly-prepared silver oxide, and then treated the filtrate with dil. sulphuric acid; or direct from a soln. of the chloride and sulphuric acid, followed by the addition of alcohol. T. Klobb, and F. M. Jäger found that the crystals are monoclinic prisms, with the axial ratios $a:b:c=1.1230:1:1.4143$, and $\beta=90^\circ 18'$; J. D. Dana thought that they were rhombic. E. Birk and W. Biltz found the sp. gr. of the anhydrous salt is 1.797 at 25°/4°; and the mol. vol. is 339.8. The mol. vol. of the NH_3 -groups is 18.65 when that of the corresponding cobaltous salt is 19.10. The subject was also discussed by W. Biltz. Analyses indicate that the air-dried crystalline product is the *pentahydrate*; E. Frémy, and J. G. Gentile, regarded the salt as a *tetrahydrate*. S. M. Jörgensen observed that the air-dried salt loses 4 mols. of water over conc. sulphuric acid, or at 100°, and the remaining molecule of the monohydrate is lost at 150°. A. Benrath and W. Kohlberg's observations are summarized in Fig. 137.

FIG. 137.—The Vapour Press of the Pentahydrate.

FIG. 138.—The Solubility of the Hexamminosulphate in Sulphuric Acid.

W. Biltz said that the salt loses its water of hydration at 150°; it remains constant in weight up to 193°; and it gives off all the ammonia at 213°. The polarization tension was studied by N. R. Dhar and G. Urbain. E. Feytis gave -0.315×10^{-6} mass unit for the magnetic susceptibility.

S. M. Jörgensen found that at 17.4°, 100 parts of water dissolve 1.41 parts of salt, and at 20°, 1.61 parts; F. Ephraim, P. Mosimann, and F. Ephraim and P. Mosimann said that at 18°, a sat. soln. has 0.015 mol or 1.792 grms. per litre; and J. N. Brønsted and A. Petersen gave 0.009 mol per litre at 0°, and 0.020 mol per litre at 20°. The subject was discussed by L. A. Hansen and J. W. Williams. The aq. soln. was found by O. W. Gibbs and F. A. Genth, and S. M. Jörgensen to be very stable, since on boiling the aq. or feebly ammoniacal soln., no perceptible decomposition occurs. A sat., aq. soln. gives a precipitate of the sulphate and chloride when treated with hydrochloric acid; potassium iodide precipitates an iodosulphate; but sulphuric acid gives no precipitate. According to A. Benrath,

and A. Benrath and H. Würzburger, the solubility determinations in sulphuric acid, Fig. 137, show that three solid phases may exist. With soln. containing up to 2.5 per cent. H_2SO_4 , the solid phase is the *pentahydrate*; with between 2.5 and 19.0 per cent. H_2SO_4 , the solid phase is **cobaltic hexamminosulphatodihydrosulphate**, $[\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3 \cdot \text{H}_2\text{SO}_4$, which forms prismatic crystals. Alcohol precipitates the normal sulphate from hot, aq. soln. The third phase is **cobaltic hexamminosulphatetetrahydrosulphate**, $[\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3 \cdot 2\text{H}_2\text{SO}_4$, stable in soln. with more than 19 per cent. H_2SO_4 . By adding an excess of sulphuric acid to a soln. of the normal sulphate, T. Klobb obtained **cobaltic hexamminosulphatodecahydrosulphate**, $2[\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3 \cdot 5\text{H}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$, in cubic crystals belonging to the rhombic bipyramidal system, with axial ratios $a : b : c = 0.9991 : 1 : 1.0006$. F. M. Jäger also made observations on the crystals. According to A. Benrath and H. Würzburger, the existence of this salt is doubtful. P. B. Sarkar and T. P. Barat prepared these three acid salts. F. Ephraim observed no evidence indicating that ammonia is taken up by the salt at -21° . O. W. Gibbs and F. A. Genth, and S. M. Jørgensen found that a sat. aq. soln. of the salt with nitric acid gives a mixed precipitate of sulphate and nitrate; hydrochloroplatinic acid precipitates a chlorosulphatinate; and yellow or brownish-yellow precipitates are formed with hydrosilicic acid, hydrochloroauric or hydrobromoauric acid, and with potassium dichromate.

Some double salts have been reported. T. Klobb reported octahedral or tabular crystals of **ammonium cobaltic hexamminosulphate**, $\text{NH}_4[\text{Co}(\text{NH}_3)_6](\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$, to be formed from a soln. of the component sulphates. The rhombic crystals have tetragonal symmetry, and the axial ratios $a : b : c = 0.9747 : 1 : 1.993$. The crystals were discussed by P. Groth, and F. M. Jäger. P. B. Sarkar and T. P. Barat prepared **potassium cobaltic hexamminosulphate**, $\text{K}_2\text{SO}_4 \cdot [\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3 \cdot 4\text{H}_2\text{O}$. F. Ephraim and P. Mosimann doubted the existence of this salt. O. W. Gibbs reported **thallium cobaltic hexamminosulphate**, $[\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3 \cdot \text{Tl}_2\text{O}(\text{SO}_4)_2 \cdot 5\text{H}_2\text{O}$, in yellow scales resembling talc; C. H. Wing reported yellow powders of **cerous cobaltic hexamminosulphate**, $[\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3 \cdot 3\text{CeSO}_4 \cdot \text{H}_2\text{O}$; **ceric cobaltic hexamminosulphate**, $[\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3 \cdot \text{Ce}_2(\text{SO}_4)_3 \cdot \text{H}_2\text{O}$; and **lanthanous cobaltic hexamminosulphate**, $[\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3 \cdot 3\text{LaSO}_4 \cdot \text{H}_2\text{O}$.

J. B. Rogojsky reported **cobaltic hexamminochlorosulphate**, $[\text{Co}(\text{NH}_3)_6](\text{SO}_4)\text{Cl} \cdot 3\text{H}_2\text{O}$, to be formed by treating the corresponding chloride with silver sulphate in the cold, and evaporating the filtrate over sulphuric acid. H. Schiff obtained the salt from eq. proportions of soln. of chloride and sulphate; J. M. Krok, by the action of chlorine on the iodosulphate; L. Jacobsen, by the action of chlorine or of silver chloride on an ammoniacal soln. of ammonium cobaltous sulphate; and T. Klobb, from a soln. of the corresponding chloride with dil. sulphuric acid or a sulphate, or from a soln. of the corresponding sulphate with dil. hydrochloric acid or a chloride. O. W. Gibbs and F. A. Genth considered that the salt is not a chemical individual, but rather a solid soln. of variable composition. The reddish-yellow rectangular prisms belong to the rhombic system. T. Klobb gave for the axial ratios, $a : b : c = 0.9986 : 1 : 1.0538$, and T. V. Barker, $0.9983 : 1 : 1.0567$. The crystals were also discussed by P. Groth and G. N. Wyrouboff. O. Hassel and G. B. Naess examined the X-radiograms and showed that the crystals possess rhombic symmetry about the c -axis. T. V. Barker gave 1.765 for the sp. gr., and 196.29 for the mol. vol. A. Benrath and W. Kohlberg found that the vap. press. curve showed the existence of the *trihydrate*, but not of the *hemihydrate* reported by H. Schiff. O. Stelling studied the X-ray spectrum. T. Klobb, and O. W. Gibbs and F. A. Genth found that the salt is sparingly soluble in cold water, and less soluble than either the normal sulphate or chloride. J. N. Brønsted and A. Petersen said that at 0° a sat. soln. contains 0.01055 mol per litre. T. Klobb reported octahedral crystals of **ammonium cobaltic hexamminochlorosulphate**, $[\text{Co}(\text{NH}_3)_6]_4(\text{SO}_4)_5\text{Cl}_2 \cdot 3(\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$, by spontaneously evaporating a mixed soln. of the chlorosulphate and ammonium sulphate. The cubic (hexakisoctahedral) crystals of the salt were discussed by F. M. Jäger. There is some doubt about its individuality. S. M. Jørgensen reported **gold cobaltic hexamminochlorosulphate**, $[\text{Co}(\text{NH}_3)_6](\text{SO}_4)(\text{AuCl}_4)$,

in orange-yellow, dichroic, rectangular prisms. J. M. Krok reported **mercuric cobaltic hexamminochlorosulphate**, $[\text{Co}(\text{NH}_3)_6](\text{SO}_4)\text{Cl}.\text{HgCl}_2$, to be formed in small, yellow prisms from soln. of the component salts.

S. M. Jörgensen reported **cobaltic hexamminobromosulphate**, $[\text{Co}(\text{NH}_3)_6](\text{SO}_4)\text{Br}$, to be formed from a soln. of the corresponding bromide and dil. sulphuric acid or ammonium sulphate; or from a soln. of the corresponding sulphate and dil. hydrobromic acid or ammonium bromide. The brownish-yellow, octahedral crystals reported by S. M. Jörgensen were found by O. Hassel, and O. Hassel and G. B. Naess to be cubic, with a face centred lattice having the parameter $a=10.51 \text{ \AA}$. The structure was also discussed by F. Ephraim and W. Flügel; the anomalous birefringence, by O. Hassel and G. B. Naess. S. M. Jörgensen reported **gold cobaltic hexamminobromosulphate**, $[\text{Co}(\text{NH}_3)_6](\text{SO}_4)(\text{AuBr}_4)$, to be formed in brownish-black, dichroic needles or plates, from soln. of the component salts.

C. W. Blomstrand, and J. M. Krok obtained **cobaltic hexamminiodosulphate**, $[\text{Co}(\text{NH}_3)_6](\text{SO}_4)\text{I}$, by boiling an ammoniacal soln. of cobaltous and ammonium sulphates, and iodine, and crystallizing the precipitate from hot water; and F. Ephraim and W. Flügel, by adding, drop by drop, a soln. of potassium iodide to one of the corresponding sulphate. O. Hassel and G. B. Naess, and O. Hassel found the yellow, octahedral crystals are isotropic and belong to the cubic system. The X-radiograms show that the face-centred lattice has 4 mols. in the unit cell, which has the parameter $a=10.71 \text{ \AA}$, that the NH_3 -groups are arranged at the apices of regular octahedron about the cobalt atoms, and that four oxygen atoms are grouped about one sulphur atom. The structure resembles that of fluorspar with the complex cobalt cation in place of the Ca-atom, and the SO_4 -groups and I-atoms in place of the F-atoms. The structure was also studied by F. Ephraim and W. Flügel. J. M. Krok added that the hot, aq. soln. gives yellow, crystalline precipitates with hydrofluosilicic acid, with potassium chromate, dichromate, or oxalate, and with sodium hydrophosphate; greyish-green precipitates with potassium ferrocyanide or ferricyanide; and mercuric chloride precipitates mercuric iodide. Chlorine displaces the iodine, but not so bromine.

A. Werner and E. Berl³ obtained **cobaltic hexahydroxylaminesulphate**, $[\text{Co}(\text{NH}_2\text{OH})_6]_2(\text{SO}_4)_3.2\text{H}_2\text{O}$, by adding conc. sulphuric acid to a well-cooled (say, -15° to -20°) soln. of the corresponding chloride. The small, yellow crystals are readily soluble in water, and decompose at 90° to 100° .

J. Meyer and K. Gröhler,⁴ and L. Lehrfeld prepared **cobaltic triethylenediaminesulphate**, $[\text{Co en}_3]_2(\text{SO}_4)_3.2\text{H}_2\text{O}$, by adding alcohol to a soln. of the hydrosulphate. The yellow, crystalline powder is readily soluble in water; it is stable in contact with dil. mineral acids; sulphuric acid does not precipitate the salt from its aq. soln.; with nitric or hydrochloric acid, a mixed sulphate and nitrate or chloride separates from the soln. Boiling the aq. soln. is attended by decomposition; and the solid salt blackens at 150° . J. Meyer and K. Gröhler obtained **cobaltic triethylenediaminehydrosulphate**, $[\text{Co en}_3](\text{HSO}_4)_3$, by dissolving 7 grms. of the corresponding chloride in 60 c.c. of cold, conc. sulphuric acid, and after standing over sulphuric acid and potassium hydroxide, in vacuo, for 24 hrs., pouring the soln. into ice-cold, absolute alcohol. If a soln. of 4.5 grms. of sulphatohydrosulphate, in 40 c.c. of ice-cold sulphuric acid, be poured into ice-cold, absolute alcohol, this salt is produced in pale yellow crystals. If a soln. of 5 grms. of this hydrosulphate, in 40 c.c. of 20 per cent., ice-cold sulphuric acid, or a soln. of 3 grms. of the normal sulphate, in 35 c.c. of 25 per cent., ice-cold sulphuric acid, be poured into ice-cold, absolute alcohol **cobaltic triethylenediaminesulphatohydrosulphate**, $[\text{Co en}_3](\text{SO}_4)(\text{HSO}_4). \frac{1}{2}\text{H}_2\text{O}$, is formed as a pale yellow oil, which can be crystallized by rubbing with a glass rod. F. M. Jäger and P. Koets reported **cobaltic triethylenediaminechlorosulphate**, $[\text{Co en}_3]_2(\text{SO}_4)\text{Cl}_2.5\text{H}_2\text{O}$, to be formed by adding the theoretical proportion of silver sulphate to a soln. of the corresponding chloride. The ditrigonal crystals have the axial ratio $a : c = 1 : 3.0285$, and $\alpha = 51^\circ 0'$.

F. M. Jäger obtained **cobaltic phenanthrolinebisethylenediaminesulphate**, $[\text{Co en}_2(\text{C}_{12}\text{H}_8\text{N}_2)]_2(\text{SO}_4)_3.12\text{H}_2\text{O}$, in pale brown crystals, by adding silver sulphate to the corresponding iodide. The triclinic crystals have the axial ratios $a : b : c = 1.4062 : 1 : 0.7362$. If a conc. soln. of chloroaquobisethylenediaminesulphate be heated with a-phenanthroline for 6 to 8 hrs., golden-yellow, dichroic, triclinic needles of **cobaltic**

phenanthrolinebisethylenediaminechlorosulphate, $[\text{Co en}_2(\text{C}_{12}\text{H}_8\text{N}_2)]_2(\text{SO}_4)\text{Cl}\cdot 2\text{H}_2\text{O}$, are formed. F. M. Jäger and P. Koets digested the chloroaquobisethylenediaminesulphate with an aq. soln. of triaminotriethylamine for 4 hrs., and then treated the soln. with silver sulphate, when brownish-red, dichroic, octahedral crystals of **cobaltic bistriaminotriethylaminesesixesethylenediaminesulphate**, $[\text{Co}_2\text{en}_6(\text{C}_6\text{H}_{18}\text{N}_4)_2]_2(\text{SO}_4)_9\cdot 8\text{H}_2\text{O}$, were formed. The axial ratios of the rhombic bipyramids were $a : b : c = 1.0131 : 1 : 1.1277$. The lowering of the f.p. of aq. soln. corresponds with a mol. wt. of 261.6, and an 85 per cent. ionization. The mol. wt. for 11 ions is 242. The mol. conductivity, μ , and the degree of ionization, α , of soln. of a mol in v litres, are :

v	53.22	77.22	102.98	137.36	183.15	366.20	109.89
μ	1210	1397	1450	1548	1635	1802	2769
α	0.43	0.50	0.52	0.55	0.59	0.65	1.0

F. M. Jäger and P. Koets also prepared brown rhombohedra of **cobaltic bistriaminotriethylaminesesixesethylenediaminechlorosulphate**, $[\text{Co}_3\text{en}_6(\text{C}_6\text{H}_{18}\text{N}_4)_4]_2(\text{SO}_4)_3\text{Cl}_{12}\cdot 10\text{H}_2\text{O}$, belonging to the trigonal system, and having the axial ratio $a : c = 1 : 3.0114$, and $\alpha = 51^\circ 10'$. G. Spăcu and R. Ripan prepared some complex pyridine salts.

E. Frémy⁵ appears to have obtained **cobaltic aquopentamminosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2(\text{SO}_4)_3\cdot 3\text{H}_2\text{O}$, in 1852, by crystallization from an aq. soln. of the hydrosulphate; P. Job used a similar process; O. W. Gibbs and F. A. Genth prepared the salt by adding conc. sulphuric acid to an oxidized ammoniacal soln. of cobaltous sulphate; S. M. Jörgensen, by evaporating a soln. of the corresponding carbonate or oxalate in $N\text{-H}_2\text{SO}_4$, and evaporating for crystallization over sulphuric acid, or precipitating the salt from its aq. soln. by alcohol; and P. Job, by the action of sulphuric acid on an ice-cold soln. of the corresponding pyrophosphate, and afterwards adding alcohol to precipitate the sulphate. O. W. Gibbs reported an isomeric, yellow variety, but S. M. Jörgensen could not confirm this result. The red, quadratic crystals, according to F. M. Jäger, are tetragonal, with the axial ratio $a : c = 1 : 1.0862$, sp. gr. 1.854 at 20° , mol. vol. 359.22; and topic axial ratios $\chi : \psi : \omega = 6.9155 : 6.9155 : 7.5115$. H. Skraup and co-workers measured the capillary rise of aq. soln. A. Werner found that the solid salt is quite stable when kept; and S. M. Jörgensen, that when dried over sulphuric acid, the salt gains 2.5 mols. of water, and it loses 3 mols. of water at 90° , without losing its acidic character. E. Frémy said that the total amount of water in the salt is $3\text{H}_2\text{O}$, but O. W. Gibbs and F. A. Genth, and C. D. Braun showed that 5 mols. in all are present; and on A. Werner's system, the salt appears as a *trihydrate*, 2 mols. belong to the two complex cations of the salt. This was confirmed by A. Benrath and W. Kohlberg's vap. press. measurements, where there is an abrupt break in the curve, corresponding with the hydrate, which he formulated: $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{SO}_3\cdot\text{H}_2\text{O})_3$. The *tetrah hydrate* reported by G. Vortmann, and C. D. Braun, was not observed by A. Benrath and W. Kohlberg. According to S. M. Jörgensen, when the salt is dehydrated beyond the trihydrate stage, it forms sulphatopentamminosulphate, and at 110° , some tetrammine is formed as well. P. Job also studied the dehydration of the salt at 75° . According to K. Matsuno, the mol. conductivity, μ , of soln. with a mol of the salt in v litres, at 25° , is :

v	100	200	400	800	1600
μ	117.0	151.8	182.2	217.0	265.1

when the soln. $v=100$ is kept for an hour, the conductivity rises from 117.0 to 143.5; this indicates that the salt is not stable in aq. soln. P. Job observed that the aquopentamminosulphate passes into the sulphato-sulphate, slowly at ordinary temp., but more rapidly at 60° ; and A. B. Lamb and J. W. Marden found that a 0.0087M-soln. of the aquopentamminosulphate, or of the sulphatopentammine sulphate, in 0.01M- H_2SO_4 , when kept 30 hrs. at 70° , contains 43.5 per cent. of aquopentamminosulphate, whichever salt was employed at the start. P. Job observed that in alkaline soln. the aquopentamminosulphate passes quantitatively into the hydroxypentamminosulphate. P. Job found the magnetic susceptibility to be -0.3×10^{-6} mass unit.

S. M. Jörgensen observed that 100 grms. of water dissolve 1.057 grms. at 17.2°; 1.20 grms. at 20.2°; 1.38 grms. at 23°; and 1.72 grms. at 27°. F. Ephraim, and J. N. Brønsted and A. Petersen found that a sat., aq. soln. at 17.5° has 0.047 mol per litre; and F. Ephraim and W. Flügel, 0.16 mol per litre at 20°. According to P. Job, when a soln. of the aquopentamminosulphate is electrometrically titrated with barium hydroxide, the curve shows a singular point when one-third of the sulphuric acid has been precipitated, and another when all is precipitated. The reactions are symbolized: $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2(\text{SO}_4)_3 + \text{Ba}(\text{OH})_2 = [\text{Co}(\text{NH}_3)_5(\text{OH})]_2(\text{SO}_4)_2 + \text{BaSO}_4 + 2\text{H}_2\text{O}$; and the intermediate compound, isolated as indicated below, then reacts in accord with the equation: $[\text{Co}(\text{NH}_3)_5(\text{OH})]_2(\text{SO}_4)_2 + 2\text{Ba}(\text{OH})_2 = [\text{Co}(\text{NH}_3)_5(\text{OH})]_2(\text{OH})_4 + 2\text{BaSO}_4$.

The effect of sulphuric acid on the solubility was studied by A. Benrath and H. Würzburger, and their results are summarized by the curve, Fig. 139, with the

FIG. 139.—The Solubility of the Aquopentamminosulphate in Sulphuric Acid.

corresponding solid phases. A. Benrath added that at 30°, with soln. having up to 15 per cent. H_2SO_4 , the solid phase is: $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2(\text{SO}_4)_3 \cdot 3\text{H}_2\text{O}$; with 15 to 35 per cent. H_2SO_4 , it is **cobaltic aquopentamminosulphatodihydrosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2(\text{SO}_4)_3 \cdot \text{H}_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$; and with over 35 per cent. H_2SO_4 , **cobaltic aquopentamminosulphatotetrahydrosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2(\text{SO}_4)_3 \cdot 2\text{H}_2\text{SO}_4$. Other acid salts have been described, but there are doubts about them. Thus, E. Frémy, C. D. Braun, J. G. Gentile, O. W. Gibbs and F. A. Genth, and S. M. Jörgensen, refer to

$4[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2(\text{SO}_4)_3 \cdot 9\text{H}_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$; and the two salts described by P. Job, $2[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2(\text{SO}_4)_3 \cdot 5\text{H}_2\text{SO}_4 \cdot 12\text{H}_2\text{O}$, and $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2(\text{SO}_4)_3 \cdot 3\text{H}_2\text{SO}_4$, whose chemical individuality he doubted. P. Job and L. O. Tao observed that the solid phase is the salt itself; for soln. with 0 to 0.5 mol of H_2SO_4 per litre, it is $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{SO}_4)(\text{HSO}_4) \cdot \text{H}_2\text{O}$, in the cold, and at 56°, it is $[\text{Co}(\text{NH}_3)_5(\text{SO}_4)]\text{HSO}_4 \cdot 2\text{H}_2\text{O}$. The tie lines for other concentrations are not concurrent, although nearly so for soln. with 4.5 to 8.5 mols H_2SO_4 per litre.

According to A. Benrath, the effect of aq. ammonia at 50° to 75° is to convert the aquopentamminosulphate into the hexamminosulphate. K. Matsuno studied the flocculating action of the salt on the hydrosol of arsenic sulphide. S. M. Jörgensen observed that hydriodic acid forms an iodosulphate; hydrochloroplatinic acid, a chlorosulphatoplatinate; and hydrofluosilicic acid gives no precipitate. Otherwise, the general reactions are those characteristic of the family—*vide supra*, the aquopentamminochloride.

No description of **cobaltic aquopentamminochlorosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{SO}_4)\text{Cl}$, is available, but J. M. Krok reported an **ammonium cobaltic aquopentamminochlorosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2\text{H}(\text{SO}_4)_3 \cdot \text{Cl} \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, to be formed by passing chlorine into a soln. of the iodosulphate, and ammonium sulphate. The dark wine-red, octahedral crystals are easily soluble in water, and no decomposition occurs when the soln. is boiled. When heated with ammonium chloride and hydrochloric acid, the chloropentamminochloride is formed. S. M. Jörgensen obtained **gold cobaltic aquopentamminochlorosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{SO}_4)(\text{AuCl}_4)$, in orange-red, dichroic, rectangular prisms, and J. M. Krok prepared **mercuric cobaltic aquopentamminochlorosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{SO}_4)\text{Cl} \cdot \text{HgCl}_2 \cdot 2\text{H}_2\text{O}$, in prismatic crystals. G. Spacu and R. Ripan prepared complexes with **cobaltic magnesium aquoquinquesbenzylaminosulphate**, $[\text{Co}(\text{C}_7\text{H}_5\text{N})_5(\text{H}_2\text{O})][\text{Co}(\text{H}_2\text{O})_6]\text{Mg}(\text{SO}_4)_3$.

J. M. Krok prepared **cobaltic aquopentamminobromosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{SO}_4)\text{Br}$, by the action of bromine on the iodosulphate; and S. M. Jörgensen, by precipitation on the addition of $N\text{-H}_2\text{SO}_4$ to a cold, aq. soln. of the bromide. The yellowish-red, octahedral crystals were found, by S. M. Jörgensen, to be stable at 100°. According to O. Hassel and co-workers,

well-formed octahedral crystals can be obtained from ammoniacal soln.; and the X-radiograms show that the face-centred, cubic lattice has the parameter $a=10.45$. The structure is almost identical with that of the hexamminobromosulphate. S. M. Jörgensen prepared **gold cobaltic aquopentamminobromosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{SO}_4(\text{AuBr}_4)$, in bronze-brown, dichroic needles.

O. W. Gibbs obtained **cobaltic aquopentamminiodosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{SO}_4)\text{I}$, by adding potassium iodide to a soln. of the corresponding sulphate; J. Kranig, by adding potassium iodide to a soln. of the carbonatosulphate; S. M. Jörgensen, and F. Ephraim and W. Flügel, by adding $2\text{N-H}_2\text{SO}_4$ to an aq. soln. of the iodide; and O. Hassel and G. B. Naess, O. Hassel, J. M. Krok, and C. W. Blomstrand, by boiling an ammoniacal soln. of cobaltous sulphate with ammonium sulphate and iodine—the first crop of crystals is the hexamminiodosulphate, and the second crop, aquopentamminiodosulphate, which, on re-crystallization from ammoniacal soln., furnishes orange-red octahedra. O. Hassel, and O. Hassel and G. B. Naess observed that the X-radiograms indicate that the iododisulphate has a face-centred, cubic lattice, with edge $a=10.62 \text{ \AA}$, and with a structure quite analogous with that of the hexammines. F. W. Clarke and H. B. Wilson found the sp. gr. to be 2.139 to 2.149 at 20.5° . F. Ephraim and W. Flügel observed that a sat., aq. soln. has 0.0163 mol of the salt per litre at 17° . J. M. Krok showed that no water is lost at 100° , and that by evaporating a soln. in ammonia, the hexammino-salt is formed; the aq. soln. gives no precipitate with hydrofluosilicic acid, or with potassium chromate or dichromate, but a greyish-green turbidity is produced with potassium ferrocyanide or ferricyanide.

S. M. Jörgensen⁶ prepared **cobaltic diaquotetramminosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]_2(\text{SO}_4)_3 \cdot 3\text{H}_2\text{O}$, by treating an aq. soln. of carbonatotetramminosulphate with dil. sulphuric acid, and then adding alcohol for precipitate; and J. V. Dubsy, by adding glacial acetic acid to a soln. of hydroxyaquotetramminosulphate in acetic acid. The small, red, quadratic prisms were thought by G. Vortmann to be a *dihydrate*; and by P. Job and L. O. Tao, a *hemipentahydrate*. A. Benrath and W. Kohlberg's measurements of the vap. press. indicate a *trihydrate*, and this agrees with A. Benrath and K. Andreas' observations on the solubility of the salt in sulphuric acid. S. M. Jörgensen found that over sulphuric acid, the salt loses 3 mols. of water without changing its general character, but when it loses the eq. of $3\frac{1}{2}$ mols. of water at 100° , there is a fundamental change. A. Uspensky and K. Tschibisoff studied the absorption spectra of aq. soln. F. Ephraim said that a sat., aq. soln. has 0.175 mol per litre at 22° ; and A. Werner added that, unlike the chloride or bromide, the sulphate is quite stable and may be kept for a long time without change. S. M. Jörgensen regarded the hydroxyaquotetramminosulphate as a basic salt. P. Job observed that in alkaline soln., the sulphate is hydrolyzed to form dihydroxytetramminosulphate. P. Job observed that when the soln. is electrometrically titrated with barium hydroxide, a singular point occurs in the curve when two-thirds of the sulphuric acid has been precipitated, and another singular point when all is precipitated. According to A. Benrath and K. Andreas, and K. Andreas, with soln. of sulphuric acid having between 0 and 35 per cent. H_2SO_4 , the solid phase is the trihydrate, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]_2(\text{SO}_4)_3 \cdot 3\text{H}_2\text{O}$; when the soln. has between 35 and 80 per cent. H_2SO_4 , the solid phase is **cobaltic diaquotetramminosulphatotetrahydrosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]_2(\text{SO}_4)_3 \cdot 2\text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$; and when over 80 per cent. H_2SO_4 is present, cobaltic sulphatoaquotetramminosulphate is formed. P. Job and L. O. Tao indicated, without proof, the formation of $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]_7\text{H}(\text{SO}_4)_{11}$ and $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]_2(\text{SO}_4)_3 \cdot \text{H}_2\text{SO}_4$. A. Benrath and K. Andreas also observed that aq. ammonia converts the diaquotetramminosulphate into hydroxypentamminosulphate; and A. Werner, that when heated with pyridine and very dil. acetic acid, the hexol-dodecammine is formed. A. Uspensky and K. Tschibisoff studied the action of carbon dioxide in converting the diaquotetramminosulphate into carbonatotetramminosulphate. F. Ephraim said that when the carbonatotetramminosulphate is treated with 25

per cent. hydrobromic acid until no more carbon dioxide is evolved, and the soln. in hydrobromic acid is cooled, **cobaltic diaquotetramminobromosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2](\text{SO}_4)\text{Br}$, is formed as a red precipitate.

A. Werner and K. R. Lange prepared **cobaltic cis-diaquobisethylenediaminesulphate**, $[\text{Co en}_2(\text{H}_2\text{O})_2]_2(\text{SO}_4)_3$, in red needles, by the action of silver sulphate on the corresponding bromide; and **cobaltic trans-diaquobisethylenediaminesulphate**, in brown plates, by the action of conc. sulphuric acid on the cold soln. followed by the addition of water. The salt loses 2 mols. of water at 80° to 90° . A. Werner prepared **cobaltic diaquobispyridinediamminosulphatohydrosulphate**, $[\text{Co}(\text{NH}_3)_2\text{Py}_2(\text{H}_2\text{O})_2]_2(\text{SO}_4)_3 \cdot 2\text{H}_2\text{SO}_4$, in brownish-violet plates, from a soln. of chloride and conc. sulphuric acid. The red, aq. soln. has an acidic reaction.

The CoA₅ or Pentammine Family

H. Schiff,⁷ C. D. Braun, and S. M. Jörgensen prepared what they regarded as basic pentammino-salts; and P. Job obtained **cobaltic hydroxypentamminosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{OH})]\text{SO}_4 \cdot 2\text{H}_2\text{O}$, by adding an eq. proportion of barium hydroxide, in aq. soln., to the aquopentamminosulphate, at 0° , and treating the filtrate with alcohol. The red, crystalline precipitate is stable when solid, but not so in aq. soln. In aq. soln., it behaves like a weak base—*vide supra*, aquopentamminosulphate. C. Duval obtained what he regarded as a persulphate, in which the SO_4 -radicle is univalent, $[\text{Co}(\text{NH}_3)_5\text{SO}_4]\text{SO}_4$, but R. Klement showed that the product should be regarded as a hydroxyamminopersulphate, $[\text{Co}(\text{NH}_3)_5(\text{OH})]\text{S}_2\text{O}_8$.

S. M. Jörgensen obtained **cobaltic hydroxyaquotetramminosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{OH})]\text{SO}_4 \cdot \text{H}_2\text{O}$, by adding alcohol to an ammoniacal soln. of the chloroaquotetramminosulphate, and he regarded it as a basic diaquotetrammine. A. Werner prepared it by adding sodium sulphate to a conc., aq. soln. of the bromide; by adding pyridine to an aq. soln. of the diaquotetramminosulphate acidified with acetic acid; or by adding alcohol to an ammoniacal soln. of the diaquotetramminosulphate, a process also employed by S. M. Jörgensen. The salt furnishes pale violet, rhombic plates. E. Rosenbohm gave -0.059×10^{-6} mass unit for the magnetic susceptibility, and the magnetic properties were studied by W. Biltz, D. M. Bose, and L. C. Jackson. S. M. Jörgensen observed that the salt furnishes a red, aq. soln. with a feeble alkaline reaction; the colour of the aq. soln., on standing, darkens, changing to brownish-violet and then to a brownish-black soln. of hexol-dodecaminosulphate; and with a warm 1:1-hydrochloric acid soln., chloroaquotetramminochloride is formed. J. V. Dubsy, A. Werner, and H. Frank observed that when a soln. in dil. acetic acid is treated with acetic anhydride, diol-octamminosulphate is formed.

S. M. Jörgensen⁸ prepared **cobaltic chloropentamminosulphate**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{SO}_4$, by triturating a mol of the chloride with 3 mols of conc. sulphuric acid, and when hydrogen chloride is no longer evolved, adding water at 70° . The warm soln. deposits crystals of the *dihydrate* and of the anhydrous salt, the cold soln. yields nearly all dihydrate. A. Benrath obtained the anhydrous salt by seeding a soln. of the dihydrate with anhydrous salt; and the dihydrate, by rapidly cooling the hot-filtered soln. S. M. Jörgensen obtained the dihydrate as a lilac precipitate consisting of fine needles when a cold soln. of a mol of the chloride is treated with 8 to 10 mols of sulphuric acid. The anhydrous salt forms purple-brown, almost black, octahedral crystals, and it is considered to be the stable form because, according to S. M. Jörgensen, it is stable in air, over sulphuric acid, or when heated to 100° ; whereas the dihydrate forms purple-red, rhombic crystals which effloresce in air, or over sulphuric acid, and at 100° . S. M. Jörgensen said that the dihydrate, which he called the unstable form, dissolves more slowly in water, and is less soluble than the anhydrous salt: 100 grms. of water, at 17.3° , dissolve 0.769 grm. of the anhydrous salt, and 0.750 of the dihydrate. The subject was discussed by A. Benrath. F. Ephraim observed that a sat., aq. soln. of the anhydrous salt contains 0.0344 mol per litre at 19° ; and J. N. Brönsted

and A. Petersen, 0.029 mol per litre at 20°. A. Werner and A. Miolati found the mol. conductivity, μ , of soln. with a mol of the salt in v litres, at 25°, to be :

v	.	.	64	128	256	512	1024	2048
μ	.	.	218.8	240.5	253.7	266.9	276.1	284.8

K. Matsuno also made measurements of the mol. conductivity. S. M. Jörgensen found that a neutral aq. soln. of the salt gives a precipitate of silver chloride when it is warmed with silver nitrate, but not so with acidic soln. ; barium hydroxide also forms a mixture of aquopentammino-chloride and hydroxide. A. Benrath measured the solubility of the salt in soln. of sulphuric acid, at 25°, and found the results indicated in Fig. 140. With 0 to 13 per cent. of H_2SO_4 , the solid phase is

$[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{SO}_4$; with 13 to 48 per cent. H_2SO_4 , it is $4[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{SO}_4 \cdot 3\text{H}_2\text{SO}_4$; and with over 48 per cent. H_2SO_4 , it is $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{SO}_4 \cdot \text{H}_2\text{SO}_4$. There is here no evidence of the formation of the **cobaltic chloropentamminosulphatohydrosulphate**, $2[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{SO}_4 \cdot \text{H}_2\text{SO}_4$, reported by H. Biltz and E. Alefeld; nor of the **cobaltic chloropentamminosulphatotritatetrahydrosulphate**, $3[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{SO}_4 \cdot 2\text{H}_2\text{SO}_4$, reported by P. Job. The zone of stability of **cobaltic chloropentamminosulphatodihydrosulphate**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{SO}_4 \cdot \text{H}_2\text{SO}_4$, is indicated in A. Benrath's Fig. 140. The salt was prepared by J. Meyer and K. Gröhler, and its X-ray absorption spectrum was studied by F. de Boer. The zone of stability of **cobaltic chloropentamminosulphatohemitrihydrosulphate**, $4[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{SO}_4 \cdot 3\text{H}_2\text{SO}_4$, is indicated in A. Benrath's Fig. 140. The salt was prepared by S. M. Jörgensen. F. M. Jäger found that the dark red needles are rhombic bipyramids with the axial ratios $a : b : c = 0.9025 : 1 : 1.609$; the sp. gr. 1.769 at 17°; the mol. vol. 789.14; and the topic axial ratios $\chi : \psi : \omega = 7.3649 : 8.1604 : 13.1300$. Y. Shibata studied the absorption spectrum. S. M. Jörgensen said water decomposes the salt into its components; cold hydrochloric acid forms chloropentamminochloride; hydrofluosilicic acid, and hydrochloroplatinic acid give characteristic precipitates; and silver nitrate gives no precipitate in the cold, and an incomplete precipitation in hot soln. K. Matsuno studied the flocculating action of the salt on the hydrosol of arsenic sulphide. S. M. Jörgensen prepared **cobaltic chloropentamminobromosulphate**, in rectangular prisms; and also **cobaltic chloropentamminoiodosulphate**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]_4 \cdot (\text{SO}_4)_3(\text{I}_3)_2$, in olive-green, rectangular plates.

A. Werner reported **cobaltic trans-chlorobisethylenediamineamminochlorosulphate**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Cl}]\text{Cl}(\text{HSO}_4)$, to be formed in ruby-red plates, by evaporating a mixture of the trans-nitroxylbisethylenediamineamminodithionate with conc. hydrochloric acid on a water-bath. The aq. soln. is strongly acidic. R. Vogel also prepared **cobaltic chlorobisethylenediaminepyridinesulphate**, $[\text{Co en}_2\text{pyCl}]\text{SO}_4$.

A. Werner and co-workers⁹—A. Klein, and A. Miolati—prepared **cobaltic cis-chloroaquatetramminosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Cl}]\text{SO}_4$, by allowing a conc., aq. soln. of acidic dichlorotetramminosulphate to stand for some time; and S. M. Jörgensen, by treating a soln. of the corresponding chloride in dil. sulphuric or nitric acid with a 20 per cent. soln. of ammonium sulphate, or by triturating the chloride with conc. sulphuric acid, and diluting the mixture with 2 vols. of water. The salt furnishes violet, rhombic or rhomboidal plates. K. Matsuno found that the mol. conductivities of soln. with a mol of the salt in 400, 800, and 1600 litres of water, at 25°, are, respectively, 190.1, 218.7, and 259.2, so that aquation, attended by a transformation into diaquatetramminosulphate, occurs in aq. soln. A. Werner and A. Miolati measured the conductivity in dil. hydrochloric

Fig. 140.—The Solubility of Chloropentamminosulphate in Sulphuric Acid.

acid soln. S. M. Jörgensen found that the salt dissolves in conc. sulphuric acid without forming hydrogen chloride, and hydrochloric acid precipitates from the soln. trans-dichlorotetramminochloride; and silver nitrate precipitates no silver chloride from the cold soln. K. Matsuno studied the flocculation of the hydrosol of arsenic sulphide by this salt.

A. Werner, and A. Werner and G. Tschernoff prepared **cobaltic chloroaquobisethylenediaminesulphate**, $[\text{Co}(\text{en}_2(\text{H}_2\text{O})\text{Cl})\text{SO}_4 \cdot 1\frac{1}{2}\text{H}_2\text{O}]$, by adding ammonium sulphate to a boiling soln. of the trans-dichlorobisethylenediaminechloride, and washing with cold water the salt which separates on cooling. The bluish-red crystals are sparingly soluble in cold water. A. Uspensky and K. Tschibisoff examined the absorption spectrum, and concluded that when the aq. soln. is warmed for a long time, aquation occurs, and a state of equilibrium with diaquochlorosulphate ensues. A. Werner observed that the addition of conc., aq. ammonia, followed by the addition of hydrobromic acid, converts the salt into chlorobisethylenediamineamminobromide; and F. M. Jäger and P. Koets studied the action of triaminotriethylamine on the salt. H. Fischlin obtained the *dextro-salt* and *laevo-salt* by the action of 50 per cent. sulphuric acid on the optically-active bromides. The reddish-brown crystals of the *monohydrate*, so formed, lose water at 40° ; and the 0.1 per cent. aq. soln. have the sp. rotations $[\alpha] = \pm 232^\circ$. F. M. Jäger prepared **cobaltic chloroaquo-phenanthrolinesulphate**. J. Meyer prepared cobaltic methylsulphatoaquotetramminomethylsulphate, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{CH}_3\cdot\text{SO}_4)(\text{CH}_3\cdot\text{SO}_4)_2]$.

S. M. Jörgensen¹⁰ prepared **cobaltic chlorodiaquotriamminosulphate**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{Cl}]\text{SO}_4$, by allowing a cold, aq. soln. of acid dichloroaquotriammine sulphate to stand for some time; and A. Werner, by heating an aq. soln. of the acid sulphate on the water-bath and allowing the soln. to crystallize in vacuo. It separates in small, lustrous crystals, is almost insoluble in water, and can also be obtained by treating chlorodiaquotriamminochloride with sulphuric acid. The dark violet, rhombic plates were found by S. M. Jörgensen to be isomorphous with those of the chloroaquotetramminosulphate. The salt is sparingly soluble in cold water. K. Matsuno studied the absorption spectrum, and found that the mol. conductivities of soln. of a mol of the salt in 800, and 1600 litres of water, are, respectively, 259.2 and 462.9, at 25° . A. Werner found that the trituration of the salt with conc. hydrochloric acid forms the violet chloride; S. M. Jörgensen, that 1:1-hydrochloric acid converts it into dichloroaquotriamminochloride; A. Werner, that the soln. in dil. soda-lye, or in contact with potassium bromide and water, converts the sulphate into triol-hexamminosulphate; and K. Matsuno, that the salt is almost insoluble in alcohol. A. Werner, and K. Matsuno studied an isomeric, bluish-grey form of the salt obtained by adding alcohol to a cold, conc., aq. soln. of dichloroaquotriamminosulphate. A. R. Klein studied the action of water, acids, and alkali-lye.

A. Werner prepared **cobaltic cis-chlorotriaquodiamminosulphate**, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_3\text{Cl}]\text{SO}_4 \cdot \text{H}_2\text{O}$, by evaporating over sulphuric acid, an aq. soln. of dichlorodiaquodiamminosulphate, acidified with sulphuric acid. The indigo-blue, crystalline mass furnishes an indigo-blue aq. soln. whose absorption spectrum was studied by K. Matsuno, and found to correspond with that of cis-diaquobisethylenediaminochloride, but not with that of the trans-salt; he also found the mol. conductivity, μ , of a soln. of a mol of the salt in v litres of water, at 25° , to be:

v . . .	100	200	400	800	1600
μ . . .	184.2	222.3	267.6	332.7	412.3

S. M. Jörgensen¹¹ prepared **cobaltic bromopentamminosulphate**, $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{SO}_4$, along with the bromosulphate, by triturating a mol of the bromochloride with 12 to 14 mols of cold, conc. sulphuric acid, diluting considerably with water after the escape of hydrochloric acid has ceased, and precipitating by addition of alcohol. If little water only be added, a blue-violet salt separates, which is most probably the acid sulphate. The normal sulphate may also be prepared from the bromobromide. It crystallizes in small, very dark violet octahedrons with brilliant lustre, which readily take up moisture and pass into the hydrated sulphate, a salt which probably contains 6 mols. of water of crystal-

lization. F. Ephraim found that a sat., aq. soln., at 20°, contains 0.0246 mol per litre. S. M. Jörgensen observed that if crystallized from dil. sulphuric acid, unstable **cobaltic bromopentamminohydrosulphate** is formed in violet needles, decomposed by water. F. Ephraim and W. Flügel said that a soln. of the salt gives no precipitate with potassium nitrilosulphonate. According to S. M. Jörgensen, if the soln. in dil. sulphuric acid be treated with a soln. of bromine and potassium iodide, unstable **cobaltic bromopentamminobromosulphate** is formed in reddish-brown plates; and with a soln. of iodine and potassium iodide, unstable **cobaltic bromopentamminiodosulphate**, $[\text{Co}(\text{NH}_3)_5\text{Br}]_4(\text{SO}_4)_3 \cdot (\text{I}_3)_2$, is formed in black, rectangular plates.

A. Werner and A. Wolberg prepared **cobaltic cis-bromo-aquatetramminosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Br}]\text{SO}_4$, in reddish- or bluish-violet crystals, by the addition of alcohol to a cold, aq. soln. of the corresponding bromide acidified with sulphuric acid; or by adding a mixture of alcohol and ether to a soln. of dibromotetramminosulphate. If the dry bromide be triturated with sulphuric acid (2 : 1), dark violet crystals of **cobaltic cis-bromo-aquatetramminobromosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Br}]_2(\text{SO}_4)\text{Br}_2$, are formed.

F. Ephraim prepared **cobaltic iodopentamminosulphate**, $[\text{Co}(\text{NH}_3)_5\text{I}]\text{SO}_4$, by triturating the nitrate with sodium sulphate and a little water. A sat., aq. soln. contains 0.00529 mol per litre at 20°.

S. M. Jörgensen¹² prepared **cobaltic sulphatopentamminosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{SO}_4)]_2\text{SO}_4 \cdot \text{H}_2\text{O}$, by slowly adding alcohol to an aq. soln. of the hydrosulphate; and P. Job, by heating diaquopentamminosulphate, at 75°, until its weight is constant. It was also prepared by C. and M. Duval. According to S. M. Jörgensen, the violet-red, feebly dichroic needles cannot be re-crystallized from water alone, owing to aquation to the aquopentamminesulphate. A. Benrath observed that the neutral sulphato-sulphate does not occur as solid phase in the presence of sulphuric acid—*vide supra*, the aquopentamminosulphate—although it can be precipitated by alcohol from a soln. of the acid sulphate. F. Ephraim and W. Flügel said that a sat., aq. soln. contains 0.3464 gram-atom of cobalt per litre at 20°. P. Job found that at 0°, benzidine chloride precipitates only one-third of the contained SO_4 -groups; but aquation occurs, so that there is a state of equilibrium between the sulphato-sulphate and the diaquo-sulphate—at 0°, about 5.5 per cent., and at 20°, about 11.3 per cent. of the diaquo-sulphate is formed. A. B. Lamb and J. W. Marden observed that a soln. of 0.0087 mol of the sulphato-sulphate per litre in 0.01M- H_2SO_4 , in 24 hrs. at 70°, suffers a 43.3 per cent. aquation. R. Schwarz and K. Tede studied the action of ultra-violet light in the transformation. For C. Duval's $[\text{Co}(\text{NH}_3)_5(\text{SO}_4)]\text{SO}_4$, *vide supra*, hydroxypentamminosulphate.

O. W. Gibbs and F. A. Genth, and S. M. Jörgensen prepared **cobaltic sulphatopentamminohydrosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{SO}_4)]\text{HSO}_4 \cdot 2\text{H}_2\text{O}$, in red prisms, by adding conc. sulphuric acid to soln. of the chloropentamminochloride or of the diaquopentamminosulphate. P. Job said that some aquopentamminosulphate is always formed by this process, and he recommended evaporating a soln. of the diaquo-sulphate in 2N- H_2SO_4 , in vacuo—the first crop of crystals furnishes the aquopentamminosulphate, and the next crop consists of the sulphato-hydrosulphate. P. Job and L. O. Tao observed that at ordinary temp., in contact with sulphuric acid of different concentrations, the solid phases are: (i) the diaquo-sulphate, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]_2(\text{SO}_4)_3 \cdot 2\frac{1}{2}\text{H}_2\text{O}$; (ii) the diaquo-sulphatohydrosulphate, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]_7(\text{SO}_4)_{10}\text{HSO}_4$; and (iii) the sulphato-hydrosulphate, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]_2(\text{SO}_4)\text{HSO}_4$. The red prisms or plates of the hydrosulphate were found by S. M. Jörgensen to be dichroic. Observations on the crystals were made by J. D. Dana, and O. W. Gibbs and F. A. Genth. F. M. Jäger observed that the rhombic bipyramids have the axial ratios $a : b : c = 0.7517 : 1 : 0.5364$. F. M. Jäger found the sp. gr. to be 1.828 at 18°; the mol. vol., 204.04; and the topic axial ratios $\chi : \psi : \omega = 5.9900 : 7.9689 : 4.2745$. J. Petersen studied the

lowering of the f.p., and the mol. conductivity of aq. soln.; and E. Feytis, the magnetic susceptibility. The *dihydrate* loses 2 mols. of water at 100° ; and 100 grms. of cold water dissolve 4 grms. of the salt. P. Job observed no hydrolysis in cold, aq. soln. According to S. M. Jørgensen, and O. W. Gibbs and F. A. Genth, warming the salt with hydrochloric acid produces the chloro-chloride; dil. hydrochloric, hydrobromic, and nitric acids give precipitates after the addition of alcohol. The salt is almost insoluble in aq. ammonia; potassium iodide precipitates the iodide from aq. soln.; crystalline precipitates are obtained with sodium chloromercurate, sodium dithionate, potassium dichromate, hydrochloroplatinic acid, and hydrochloroauric acid; and ammonium oxalate, potassium cobalticyanide, and sodium pyrophosphates give no precipitates. K. Matsuno studied the constitution of these salts.

F. Ephraim and W. Flügel prepared **cobaltic sulphatopentamminochloride**, $[\text{Co}(\text{NH}_3)_5(\text{SO}_4)]\text{Cl}$, by alcohol precipitation from a soln. of the acid sulphate in dil. hydrochloric acid. The rose-red precipitate has a bluish tinge. A sat., aq. soln. contains 0.2881 gram-atom of cobalt per litre. Barium chloride does not precipitate sulphate from the cold, aq. soln. The salt is insoluble in alcohol. It was also prepared by C. and M. Duval. By adding alcohol to a soln. of the acid sulphate in dil. hydrobromic acid, S. M. Jørgensen prepared **cobaltic sulphatopentamminobromide**, $[\text{Co}(\text{NH}_3)_5(\text{SO}_4)]\text{Br}$, as a precipitate which crystallizes from conc., aq. soln. with the addition of hydrobromic acid (1 : 1), in violet-red, dichroic, rectangular plates. Measurements of the lowering of the f.p. were made by J. Petersen. A. Werner and A. Miolati also found that soln. with a mol of the salt in 32, 256, and 1024 litres, had the mol. conductivities 79.34, 101.6, and 114.2, respectively. Aquation thus occurs in dil., aq. soln. F. Ephraim and W. Flügel observed that the sat., aq. soln., at 20° , contains 0.0500 gram-atom of cobalt per litre. S. M. Jørgensen found that silver nitrate gives an immediate precipitate of silver bromide, but barium chloride gives a precipitate of barium sulphate only after the soln. has been warmed. F. Ephraim and W. Flügel prepared **cobaltic sulphatopentamminiodide**, $[\text{Co}(\text{NH}_3)_5(\text{SO}_4)]\text{I}$, in small, red prisms, by treating the corresponding chloride with potassium iodide at 50° . The sat., aq. soln. contains 0.0371 gram-atom of cobalt at 20° . C. and M. Duval prepared cobaltic persulphatopentamminochloride.

P. Job prepared **cobaltic sulphatoaquotetramminosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SO}_4)]_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, in red crystals, from an aq. soln. of the acid sulphate. The *dihydrate* is only sparingly soluble in water, and the aq. soln. is not stable, for, by aquation, it forms diaquotetramminosulphate. J. Meyer and K. Gröhler obtained the *tetrahydrate* by exposing the sulphate, dried at 110° , in air; F. Ephraim and W. Flügel, by adding alcohol to a soln. of the carbonatotetramminonitrate in cold, dil. sulphuric acid; and W. Schramm, by adding alcohol to a soln. of the diaquotetramminosulphate in malonic acid. The tetrahydrate forms cherry-red, acicular crystals which are easily soluble in water; barium chloride precipitates barium sulphate from the cold, aq. soln., and there is another precipitation after the soln. has been boiled. The salt loses 4 mols of water at 110° , and decomposes at a higher temp. The anhydrous salt forms a bluish-violet soln. in water, which soon becomes cherry-red. The sat., aq. soln. has 0.1254 gram-atom of cobalt per litre at 20° . A soln. of cobaltic chloronitritotetramminochloride in cold, conc. sulphuric acid, when treated in the cold with absolute alcohol, furnishes the *dialcoholate*, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SO}_4)]_2\text{SO}_4 \cdot 2\text{C}_2\text{H}_5\text{OH}$. This salt loses the alcohol at 80° , and when the residue is exposed to air, it forms the tetrahydrate. P. Job prepared **cobaltic sulphatoaquotetramminohydrosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SO}_4)]\text{HSO}_4 \cdot 1\frac{1}{2}\text{H}_2\text{O}$, or $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SO}_4)]_2\text{SO}_4 \cdot \text{H}_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$, in violet crystals, by evaporating a sulphuric acid (1 : 4) soln. of carbonatotetramminosulphate, or diaquotetramminosulphate on a water-bath, or in vacuo; and A. Benrath and K. Andreas, and K. Andreas, observed that when the diaquo-sulphate is in contact with over 80 per cent. sulphuric acid, it behaves like the pentamminosulphate, forming, at 25° , a

syrupe liquid which, at a low temp., furnishes crystals of the hydrosulphate, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SO}_4)]_2\text{SO}_4 \cdot \text{H}_2\text{SO}_4$, *i.e.* $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{SO}_4)]\text{HSO}_4$. P. Job studied the constitution by electrometric titration of the soln. with barium hydroxide, and the results indicate that an aquo-salt is formed which dissociates into a hydroxyl-salt and H^+ -ions.

A. Werner prepared **cobaltic sulphatodiaquotriamminosulphate**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_2(\text{SO}_4)]_2\text{SO}_4 \cdot \text{H}_2\text{O}$, by adding the requisite quantity of silver sulphate to a warm, conc. soln. of dichloroaquotriamminochloride and evaporating the filtrate from the silver chloride in vacuo. The residue is extracted with water, when the salt is left undissolved; by evaporating the soln. and again extracting with water, a further quantity of the insoluble salt is obtained. It is a reddish-violet powder, insoluble in water, but soluble in conc. hydrochloric, nitric, and sulphuric acids. When mixed with conc. hydrochloric acid, it yields chlorodiaquotriamminosulphate, and by the prolonged action of the acid, the dichloroaquochloride.

The CoA_4 or Tetrammine Family

A. Werner¹³ obtained **cobaltic cis-dichlorotetramminosulphate**, $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]_2\text{SO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$, in bluish-violet crystals, from a well-cooled soln. of the corresponding chloride in sulphuric acid (1:1). The salt is very sparingly soluble in water. There is no loss in weight over phosphorus pentoxide; but when heated to 70° or 80° , there is a loss of about 1.22 per cent., presumably owing to a partial decomposition of the salt.

E. Schmidt, and A. Werner and A. Klein prepared **cobaltic trans-dichlorotetramminohydrosulphate**, $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{HSO}_4$, by treating the solid carbonato-tetramminochloride, $[\text{Co}(\text{NH}_3)_4\text{CO}_3]\text{Cl}$, with conc. hydrochloric acid in a freezing mixture, dissolving the product in conc. sulphuric acid, and adding hydrochloric acid as long as a precipitate is formed; the mixture is then allowed to remain for a few days in a closed flask, and the precipitate collected and washed with alcohol and ether; it is easily purified by dissolving it in water and precipitating with dil. sulphuric acid. S. M. Jörgensen obtained it by the action of conc. sulphuric acid on the chloroaquotetramminochloride, or diaquotetramminosulphate. The salt was also prepared by A. Werner and A. Wolberg. It forms bright green needles, freely soluble in water. A. Werner and A. Miolati found that the conductivity of the aq. soln. increases with time, owing to the formation of chloroaquotetramminosulphate. Thus, the mol. conductivity of a soln. of a mol of the salt in 256 litres, at 25° , increases in 45 mins. from 372.7 to 426.5. A. Werner and A. Klein found that the salt is easily soluble in water, and has a strongly acidic reaction. With hydrochloric acid and chlorides, it yields a bright green, crystalline precipitate of dichlorotetramminochloride; it is decomposed by mercurous nitrate, potassium cyanide, and potassium ferrocyanide, and dissolves in conc. sulphuric acid, with a red coloration and the evolution of hydrogen chloride. It is more stable in aq. soln. than the other salts of the series, but the colour of the soln. gradually changes to blue, violet, becomes colourless, and finally red. When the conc., aq. solution is warmed, a precipitate of chloroaquotetramminosulphate, $[\text{Co}(\text{NH}_3)_4\text{Cl}(\text{H}_2\text{O})]\text{SO}_4$, is obtained in the form of lustrous, reddish-violet plates; this dissolves in conc. sulphuric acid, with a violet coloration, and when treated with conc. hydrochloric acid in aq. soln., yields chloroaquotetramminochloride. A. Werner, and T. S. Price and S. A. Brazier discussed the constitution of the double salts. A. Werner and A. Klein observed that **silver cobaltic dichlorotetramminosulphate**, $[\text{Co}(\text{H}_2\text{O})_4\text{Cl}_2]\text{SO}_4\text{Ag}$, is obtained as a flocculent, bright green precipitate by mixing soln. of eq. proportions of the hydrosulphate and silver nitrate at a low temp.; and **bismuth cobaltic dichlorotetramminosulphate**, $\text{Bi}[\text{Co}(\text{NH}_3)_4\text{Cl}_2]_3(\text{SO}_4)_3$, is similarly produced as a green, pulverulent precipitate.

A. Werner and R. Feenstra prepared **cobaltic trans-dichloroquaterpyridinehydrosulphate**, $[\text{Co}(\text{C}_5\text{H}_5\text{N})_4\text{Cl}_2]\text{HSO}_4 \cdot 2\text{H}_2\text{O}$, in green plates and needles, by the action of dil.

sulphuric acid on an aq. soln. of the chloride, and re-crystallization from aq. soln. at 50°. A. Werner prepared **cobaltic cis-dichlorobisethylenediaminesulphate**, $[\text{Co en}_2\text{Cl}_2]_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, in small, reddish-violet needles, by treating a conc., aq. soln. of the chloride with ammonium sulphate; or by evaporating the mother-liquor obtained in the preparation of chloroaquobisethylenediaminesulphate. A. Gordienko studied the absorption spectrum. A. Werner and G. Tschernoff obtained the *dextro-salt*, and the *levo-salt* by the action of ammonium sulphate on sat., aq. soln. of the corresponding chlorides. The sp. rotation of a 0.25 per cent. aq. soln. of the *dextro-salt* is $[\alpha] = 180^\circ$, and the *levo-salt*, -182° . A. Werner, and L. Cohn prepared **cobaltic trans-dichlorobisethylenediaminehydrosulphate**, $[\text{Co en}_2\text{Cl}_2]\text{HSO}_4$, as a green, crystalline precipitate, by the action of sulphuric acid on an aq. soln. of the chloride, and re-crystallization from water acidulated with sulphuric acid. If a well-cooled, aq. soln. be treated with silver nitrate, green plates of **silver cobaltic dichlorobisethylenediaminesulphate**, $[\text{Co en}_2\text{Cl}_2]_2\text{SO}_4 \cdot 2\text{AgNO}_3$, are formed. The salt is stable, and sparingly soluble in water. Its constitution was discussed by A. Werner, and T. S. Price and S. A. Brazier. A. Werner and A. Frölich found that **trans-cobaltic dichlorobispropylenediaminehydrosulphate**, $[\text{Co pn}_2\text{Cl}_2]\text{HSO}_4 \cdot 2\text{H}_2\text{O}$, is formed in green, soluble needles, from a soln. of the corresponding chloride in conc. sulphuric acid. If the acid sulphate be treated with silver nitrate, there are formed malachite-green scales of a complex with silver nitrate. A. Werner and F. Chaussy obtained **cobaltic trans-dichloroethylenediaminediamminohydrosulphate**, $[\text{Co}(\text{NH}_3)_2\text{enCl}_2]\text{HSO}_4 \cdot \text{H}_2\text{O}$, as a green to brown precipitate, by adding 1:1-sulphuric acid to a conc., aq. soln. of the corresponding chloride at -4° .

S. M. Jörgensen, and A. Werner prepared **cobaltic dichloroaquotriamminohydrosulphate**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{Cl}_2]\text{HSO}_4$, by mixing the dichloroaquotriamminochloride to a thin paste with a cool mixture of conc. sulphuric acid (2 vols.) and conc. hydrochloric acid (1 vol.), and after the mixture has remained for 1 hr., spreading the paste on a porous plate. This operation is repeated three times, and the product then washed with alcohol until free from acid, and dried over sulphuric acid. It is a greyish-green, crystalline powder, and dissolves fairly easily in water, yielding a green solution which quickly changes to indigo-blue; the solution has an acid reaction. It is obtained in black, lustrous, prismatic crystals by adding conc. sulphuric acid to the cold, conc., aq. soln. and evaporating the clear liquid in vacuo over sulphuric acid. S. M. Jörgensen found that 100 grms. of water dissolve 16 to 20 grms. of the salt. Aquation occurs in aq. soln. to form chlorodiaquotriamminosulphate, which, according to A. Werner, has precipitated this product from the blue soln. by alcohol. The double salt, **silver cobaltic dichloroaquotriamminosulphate**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{Cl}_2]\text{AgSO}_4$, is produced by thoroughly mixing the acid sulphate with a small quantity of silver nitrate soln., and washing the product with absolute alcohol. It is a grass-green powder which quickly decomposes and darkens, and it is decomposed by water, with the separation of silver chloride.

A. Werner prepared **cobaltic dichlorodiaquodiamminohydrosulphate**, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_2\text{Cl}_2]\text{HSO}_4$, by adding potassium tetranitritodiamminocobaltate (3 grms.) to a mixture of equal vols. of sulphuric and hydrochloric acids, cooled with ice and salt, and allowing the mixture to remain some hours in the freezing mixture. After 24 hrs., the product is washed with alcohol and ether, dissolved in ice-cold water, and precipitated with sulphuric acid. A. Werner and R. Feenstra obtained it from ammonium tetranitritodiamminocobaltate. The salt crystallizes in lustrous, malachite-green needles, soluble in water, to form a green soln. with an acidic reaction, and which quickly changes to a blue soln. which, with alcohol, gives a precipitate of chlorotriaquodiamminosulphate. The same product is obtained by slowly evaporating the soln. K. Matsuno showed that the aq. soln. probably contains different aquo-salts in equilibrium; he studied the absorption spectrum, and the flocculating action of the salt on the hydrosol of arsenic sulphide.

A. Werner and A. Wolberg prepared **cobaltic dibromotetramminosulphate**, $[\text{Co}(\text{NH}_3)_4\text{Br}_2]_2\text{SO}_4$, in small, green crystals, by the action of sulphuric acid on the corresponding chloride. The salt is freely soluble in water, and it rapidly changes in aq. soln., to form the aquo-salt.

A. Werner and G. Tschernoff prepared optically active **cobaltic cis-bromochlorobisethylenediaminesulphate**, $[\text{Co en}_2\text{Cl Br}]_2\text{SO}_4 \cdot \text{H}_2\text{O}$, as a pale violet, crystalline powder,

by treating the corresponding nitrate with conc. sulphuric acid. The sp. rotation of a dil. soln. of the *dextro*-salt is $[\alpha] = 144^\circ$, and of the *levo*-salt, -148° . J. C. Duff prepared **cobaltic sulphatobisethylenediaminebromide**, $[\text{Co en}_2(\text{SO}_4)]\text{Br} \cdot \text{H}_2\text{O}$, by evaporating a soln. of carbonatobisethylenediaminebromide treated with an eq. proportion of $\text{N-H}_2\text{SO}_4$. These salts were studied by P. Job, and F. Ephraim and W. Flügel. The dark red crystals lose their water of hydration in air; barium chloride precipitates barium sulphate from the aq. soln. only after it has been heated. The mol. conductivity, μ , of a soln. of a mol of the salt in v litres, at 25° , is:

v	.	.	.	32	64	128	256	512	1024
μ	.	.	.	90.4	98.56	106.9	114.0	119.7	125.2

Complexes with Two or More Cobalt Atoms

The nature of the products obtained by the slow oxidation of ammoniacal soln. of cobaltous sulphate, as well as of G. Vortmann's salt,¹⁴ or *cobaltic fuscousulphate*, have been discussed in connection with *cobaltic melanochloride*, etc.; and it was prepared by C. Schwenk. E. Frémy, and G. Vortmann reported a brown salt, $\text{Co}_2(\text{NH}_3)_8(\text{OH})_2(\text{SO}_4)_2 \cdot 3\text{H}_2\text{O}$, whose constitution has not been determined.

E. Frémy prepared what has since been shown to be **cobaltic peroxo-decamminodisulphate**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5](\text{SO}_4)_2 \cdot 3\text{H}_2\text{O}$, by the slow oxidation of an ammoniacal soln. of cobaltous sulphate. The olive-brown prisms were considered to be the *trihydrate*, G. Vortmann said the *tetrahydrate*. The salt is soluble in water, but the soln. decomposes, with the evolution of oxygen; the soln. in aq. ammonia is stable. It gives reactions similar to those of the nitrate. According to G. Vortmann, **cobaltic peroxo-decamminohydrosulphate**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5](\text{HSO}_4)_4 \cdot \text{H}_2\text{O}$, is obtained by adding the sulphate to sulphuric acid 1 : 1. The cinnabar-red precipitate is the *monohydrate*. If the sulphate be added to a mixture of equal vols of sulphuric acid, water, and alcohol, the *pentahydrate* is formed. The salts are stable in air at 13° , but at 20° , they become green, owing to decomposition. The aq. soln. also decomposes with the deposition of cobaltous sulphate and the evolution of oxygen. If the sulphate be treated with conc. hydrochloric acid, a brownish-violet precipitate of **cobaltic peroxo-decammino-hydrochlorosulphate**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5](\text{SO}_4)\text{Cl}_2 \cdot 4\text{HCl} \cdot \text{H}_2\text{O}$, is produced.

L. Maquenne obtained a salt which was afterwards shown to be **cobaltic peroxo-decamminohemipentasulphate**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5]_2(\text{SO}_4)_5 \cdot 8\text{H}_2\text{O}$, by passing ozonized oxygen through an ammoniacal soln. of cobaltous sulphate, when the colour changes to brown, then green, and finally deposits dark green crystals on the sides of the containing vessel. He said:

The salt can be easily obtained by passing a rapid current of air through a mixture of 100 c.c. ammonia with 10 c.c. of a sat. soln. of cobalt sulphate for about 2 hours. The precipitated crystals are collected, dried rapidly between filter-paper, and thrown, in small portions at a time, into 25 c.c. of a cooled mixture of equal vols. of sulphuric acid, alcohol, and water, when the brown substance becomes rose-coloured. On adding an excess of chlorine-water, the rose-coloured compound becomes green, and the liquid, if heated to boiling, and left to cool, deposits prismatic crystals which are sometimes as much as 5 mm. long, and can be obtained larger by re-crystallization from dil. (5 per cent.) sulphuric acid.

G. Vortmann found that the same product is obtained by re-crystallizing the acid sulphate from water; or, by treating the tetranitrate with cold 1 : 1-sulphuric acid for some hours, diluting with water and warming the mixture for complete dissolution. The acid nitratosulphate separates out on cooling, and when this product is re-crystallized from water it yields green crystals of the hemipentasulphate. L. Maquenne said that the crystals are dark green, almost black, quadratic prisms; they are but slightly soluble in water, by which they are decomposed with evolution of oxygen, but they dissolve easily in dilute acids without sensible decomposition, even at 100° , if the operation is conducted rapidly. By prolonged ebullition with acids, this compound is converted into a rosecobalt salt. It is entirely decomposed by the fixed alkalis, with evolution of oxygen and precipitation of black cobaltic oxide. Conc. hydrochloric acid converts the sulphate into the correspond-

ing chloride. According to G. Vortmann, the acid salt prepared by L. Maquenne is a hydrosulphate; and the former obtained **cobaltic peroxo-decamminosulphato-dihydrosulphate**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5]_2(\text{SO}_4)_5 \cdot 2\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, by treating the tetrasulphate with a cold, sat. soln. of potassium permanganate and sulphuric acid (1 : 5); when the red colour has disappeared, the soln. is boiled. The dark bluish-green prisms are almost black, they lose water at 110° , and at 130° are decomposed. When re-crystallized from water, the normal sulphate is produced, and when re-crystallized from dil. sulphuric acid, **cobaltic peroxo-decamminosulphatomono-hydrosulphate**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5]_2(\text{SO}_4)_5 \cdot \text{H}_2\text{SO}_4$, is produced. When the chloride of this series of salts is treated with 1 : 1-sulphuric acid, grass-green crystals of **cobaltic peroxo-decamminochlorosulphate**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5](\text{SO}_4)_2\text{Cl} \cdot 3\text{H}_2\text{O}$, are formed.

A. Werner prepared **cobaltic μ -amino-decamminosulphate**, $[(\text{NH}_3)_5\text{Co}-\text{NH}_2 \cdots \text{Co}(\text{NH}_3)_5]_2(\text{SO}_4)_5 \cdot 6\text{H}_2\text{O}$, by treating a soln. of the bromide with a conc., aq. soln. of sodium sulphate. The rose-red needles are soluble in water; they are stable at 85° , but are slowly decomposed at 100° . A. Werner and F. Salzer prepared **cobaltic chloroaquo- μ -amino-octamminosulphate**, $[(\text{H}_2\text{O})(\text{NH}_3)_4\text{Co}-\text{NH}_2 \cdots \text{Co}(\text{NH}_3)_4\text{Cl}](\text{SO}_4)_2 \cdot \text{H}_2\text{O}$, by treating a freshly-prepared soln. of the chloride with dil. sulphuric acid. The reddish-violet crystals are insoluble in water; at 105° , the water of aquation is given off. A. Werner prepared the corresponding **cobaltic bromoaquo- μ -amino-octamminosulphate**, $[(\text{H}_2\text{O})(\text{NH}_3)_4\text{Co}-\text{NH}_2 \cdots \text{Co}(\text{NH}_3)_4\text{Br}](\text{SO}_4)_2 \cdot \text{H}_2\text{O}$, by treating an ice-cold soln. of the bromide with 1 : 1-sulphuric acid. The dark brown crystals are almost insoluble in water.

A. Werner and A. Baselli prepared **cobaltic sulphato- μ -amino-octammino-hydrosulphate**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{SO}_4) \cdots \text{Co}(\text{NH}_3)_4\text{H}(\text{SO}_4)_2]$, by heating the corresponding chloride with conc. hydrochloric acid, on a water-bath, as long as hydrogen chloride is evolved, and then pouring the mixture into ice-cold water. A. Werner and F. Salzer recommended heating 3 grms. of μ -amino-ol-octamminochloride with 10 c.c. of water and 2 c.c. of conc. sulphuric acid until a clear, violet soln. is obtained; purple-violet, prismatic leaflets are deposited on cooling. The salt can be re-crystallized from dil. sulphuric acid. The salt is almost insoluble in water, and the soln. reacts acidic to litmus. A. Werner, F. Steinitzer and K. Rücker obtained **cobaltic sulphato- μ -amino-octamminochloride**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{SO}_4) \cdots \text{Co}(\text{NH}_3)_4]\text{Cl}_3 \cdot 2\text{H}_2\text{O}$, by triturating the corresponding nitrate with hydrochloric acid. The violet crystals can be re-crystallized from water. Y. Shibata studied the absorption spectrum. A. Werner and co-workers added that when this salt is heated for 6 hours at 110° , it loses a mol. of hydrogen chloride, and is converted into the sulphato-chloride, a small quantity of imido-octamminedicobaltsulphate being formed at the same time. A. Werner and A. Baselli prepared **cobaltic sulphato- μ -amino-octamminobromide**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{SO}_4) \cdots \text{Co}(\text{NH}_3)_4]\text{Br}_3 \cdot \text{H}_2\text{O}$, by treating the nitrate or hydrosulphate with hydrobromic acid; and A. Werner, by adding hydrobromic acid to a soln. of the hydrosulphate; and by boiling μ -amino-ol-octamminobromide with water and dil. sulphuric acid, and mixing the cold soln. with hydrobromic acid. The silky, violet needles lose no water over sulphuric acid, but the salt becomes anhydrous at 110° . A. Werner and A. Baselli added sodium or potassium iodide to a soln. of the chloronitrate, and obtained a dark brown, crystalline precipitate of **cobaltic sulphato- μ -amino-octamminoiodide**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{SO}_4) \cdots \text{Co}(\text{NH}_3)_4]\text{I}_3$. A. Werner prepared **cobaltic sulphato- μ -aminoquaterethylenediaminebromide**, $[\text{en}_2\text{Co}=(\text{NH}_2)(\text{SO}_4) \cdots \text{Co} \text{en}_2]\text{Br}_3$, as a red, crystalline powder, by treating the corresponding thiocyanate, or nitrate with ammonium bromide.

A. Werner prepared **cobaltic diol-octamminosulphate**, $[(\text{NH}_3)_4 \cdots \text{Co}(\text{OH})_2 \cdots \text{Co}(\text{NH}_3)_4](\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}$, by heating cobaltic hydroxyaquotetramminosulphate, between 100° and 110° , until its weight is constant; and H. Frank, by heating that salt with ten times its weight of acetic anhydride, or by treating the corresponding chloride with sodium sulphate. The violet-red needles are sparingly soluble in

water; and, according to H. Frank, the salt is not changed by warming it with acetic anhydride. A. Werner also prepared **cobaltic diaquo-diol-hexamminosulphate**, $[(\text{H}_2\text{O})(\text{NH}_3)_3\text{Co} \cdots (\text{OH})_2 \cdots \text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})](\text{SO}_4)_2 \cdot 3\text{H}_2\text{O}$, by digesting an aq. soln. of dinitrato-diol-hexamminonitrate for 24 hrs. and then adding sodium sulphate. The bluish-violet crystals are sparingly soluble in water.

According to A. Werner, when cobaltic melanochloride (*q.v.*) is prepared by the exposure of ammoniacal cobalt chloride solns. to the air, at temps. below 5° , and then worked up with silver nitrate, it yields a brownish-black nitrate in addition to the salts of the μ -amino-peroxo-ol-hexammines. From this brownish-black nitrate, **cobaltic hydroxyammino-peroxo-ol-hexamminosulphate**, $[(\text{OH})(\text{NH}_3)_3\text{Co} = (\text{OH})(\text{O}_2) \cdots \text{Co}(\text{NH}_3)_3(\text{OH})_2(\text{SO}_4)_3]$, is obtained by treating it with an excess of ammonium bromide. The bromide is dissolved in dil. acetic acid and treated with ammonium sulphate. The dark green salt which separates is boiled many times with dil. acetic acid, or the double salt with ammonium sulphate is dissolved in water acidulated with acetic acid, and allowed to crystallize. The brownish-black crystals dissolve sparingly in water, and the soln. has an alkaline reaction. The salt is readily soluble in dil. acetic acid. On heating the salt with conc. sulphuric acid, it is decomposed with evolution of oxygen and nitrogen, the volumes of these gases obtained showing that the compound contains a peroxo-group and tervalent and quadrivalent cobalt. The double salt, **ammonium cobaltic hydroxyammino - peroxo - ol - hexammino - sulphate**, $[(\text{OH})(\text{NH}_3)_3\text{Co} = (\text{OH})(\text{O}_2) \cdots \text{Co}(\text{NH}_3)_3(\text{OH})_2(\text{SO}_4)_2\text{NH}_4 \cdot \text{H}_2\text{O}]$, is precipitated when glacial acetic acid is added to a soln. of the nitrate saturated with ammonium sulphate. The black crystals are readily soluble in water; and if an acetic acid soln. of the salt is boiled, and cooled, the normal sulphate is deposited.

A. Werner and co-workers—F. Beddow, and A. Grün—prepared **cobaltic μ -amino-peroxo-octamminosulphate**, $[(\text{NH}_3)_4\text{Co} = (\text{NH}_2)(\text{O}_2) \cdots \text{Co}(\text{NH}_3)_4](\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}$, by treating an aq. soln. of another salt of the series with dil. sulphuric acid. The greenish-grey, crystalline precipitate is insoluble in water; but it forms a yellowish-brown soln. with conc. sulphuric acid, and when this soln. is diluted with water, the original salt is recovered unchanged. When the crystals are triturated with conc. hydrochloric or nitric acids, the corresponding chloride or nitrate is formed.

A. Werner and A. Baselli prepared **cobaltic μ -amino-ol-octamminosulphate**, $[(\text{NH}_3)_4\text{Co} = (\text{NH}_2)(\text{OH}) \cdots \text{Co}(\text{NH}_3)_4](\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}$, by adding sulphuric acid to a sat., aq. soln. of the corresponding chloride; or by shaking the chloride with an acetic acid soln. of silver nitrate, and treating the filtrate with sulphuric acid. The garnet-red or brownish-red, prismatic crystals are insoluble in water. They lose their water of hydration over phosphorus pentoxide; and when heated with conc. sulphuric acid, cobaltous sulphate is formed, and nitrogen is evolved.

A. Werner prepared **cobaltic triol-hexamminosulphate**, $[(\text{NH}_3)_3\text{Co} \cdots (\text{OH})_3 \cdots \text{Co}(\text{NH}_3)_3](\text{SO}_4)_3 \cdot 6\text{H}_2\text{O}$, by the action of soda-lye on chlorodiaquotriamminosulphate; or by treating the corresponding chloride or bromide with a cold, sat. soln. of sodium sulphate. The red, scaly crystals quickly lose 5 mols. of water when confined over phosphorus pentoxide, and the remaining mol. of water is lost more slowly. All the water is expelled at 70° , and the salt decomposes at 100° . The salt is sparingly soluble in cold water; and when treated with nitric acid (1 : 1), the diol-group is nitrated to form $[\text{Co}_2(\text{NH}_3)_6(\text{OH})_2(\text{NO}_3)_2(\text{NO}_3)_2]$. A. Werner noted that the mother-liquor obtained in preparing cobaltic triol-hexamminosulphate deposits, on cooling, a dark green, crystalline precipitate of **cobaltic hexol-hexamminosulphate**, $[\text{NH}_3)_3\text{Co} \equiv (\text{OH})_3 \cdots \text{Co} \cdots (\text{OH})_3 \equiv \text{Co}(\text{NH}_3)_2](\text{SO}_4)_3]$.

A. Werner and G. Jantsch prepared **cobaltic diaquo-tetrol-quaterethylenediaminesulphate**, $[\text{en}_2\text{Co} = (\text{OH})_2 \cdots \text{Co}(\text{H}_2\text{O})_2 \cdots (\text{OH})_2 = \text{Co en}_2](\text{SO}_4)_3 \cdot 5\text{H}_2\text{O}$, by treating the corresponding chloride (*q.v.*) with sodium sulphate, when microscopic, red needles of the *pentahydrate* are formed. Again, a soln. of cobalt sulphate containing ethylenediamine, deposits, on exposure to the air, the sulphate in the form of red

needles. It cannot be re-crystallized, being sparingly soluble in water, but when treated with barium chloride and then with sodium sulphate, the *heptahydrate* is formed. Both salts are almost insoluble in water, and lose their water of hydration over phosphorus pentoxide.

S. M. Jørgensen¹⁵ prepared **cobaltic hexol-dodecammino-sulphate**, $[\text{Co}\{\text{(OH}_2 = \text{Co}(\text{NH}_3)_4\}_3(\text{SO}_4)_3 \cdot 9\text{H}_2\text{O}$, by keeping an ammoniacal or an alkaline soln. of chloroaquotetramminosulphate in the cold; by treating an aq. soln. of the corresponding chloride with ammonium sulphate; and by the action of *N*- NH_4OH on diaquotetramminosulphate. A. Werner and E. Berl prepared it by heating dibromotetramminobromide with a little water until bromine is evolved, and treating the soln. of the product with a soln. of ammonium sulphate; it is also obtained by adding pyridine to a hot, dilute, acetic acid soln. of diaquo-tetramminosulphate. According to A. Werner and E. Berl, the dark brownish-violet or black, tabular crystals, when washed with water, alcohol, and ether, furnish the *enneahydrate*; if dried over calcium chloride, the *hexahydrate*; and over sulphuric acid, or at 98°, the *tetrahydrate*. The salt is broken down by hydrochloric acid—*vide supra*, the chloride; boiling, dil. sulphuric acid liberates oxygen; and hot, conc. sulphuric acid liberates oxygen and nitrogen. According to S. M. Jørgensen, the salt is sparingly soluble in water, and the brownish-violet, aq. soln. gives quantitative precipitates with sodium chloromercurate, potassium chromate, and hydrochloroplatinic acid.

§ 25. Cobaltous Carbonate

A. Weisbach¹ described a mineral which occurs sparingly with roselite, $(\text{Co}, \text{Mg}, \text{Ca})_3(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$, at Schneeberg, Saxony, and he called it **sphaerocobaltite**. Analyses reported by A. Weisbach, and A. A. Ferro correspond with **cobaltous carbonate**, CoCO_3 . A. A. Ferro found the mineral at Libiola, Italy; M. Baccaredda, at Liguria, Italy; and A. Schoep, at Katanga, Belgian Congo. H. de Sénarmont found 0.13 per cent. of cobalt associated with the copper carbonate at Przibram. J. C. Booth described a rose-red incrustation on the serpentine at a copper mine near Finksburg, Maryland; he regarded it as a hydrated cobaltous carbonate, and he called it **remingtonite**—after E. Remington. E. V. Shannon showed that remingtonite is not a carbonate, but a kind of serpentine coloured with cobalt. The optical data by E. S. Larsen for a variety from California, are taken to refer to an anhydrous carbonate of the rhombohedral or trigonal series—possibly a cobaltiferous smithsonite, ZnCO_3 .

H. de Sénarmont prepared cobaltous carbonate by heating a soln. of cobalt chloride with calcium carbonate, in a sealed tube, at 150° for 18 hrs.; or a soln. of sodium hydrocarbonate, saturated with carbon dioxide, mixed with cobalt chloride, in a sealed tube, at 140° . A. Barth obtained a theoretical yield by electrolyzing a soln. of a halide of the alkalis or alkaline earths with a cobalt anode whilst carbon dioxide is passing through the soln. B. Bruzs could not

prepare the anhydrous carbonate by heating one of the hydrates in carbon dioxide.

H. St. C. Deville found that precipitated cobalt carbonate dissolves in a soln. of ammonium hydrocarbonate, and deposits tabular crystals of a double salt which gradually passes into a violet-red powder of the *tritadihydrate*, $\text{CoCO}_3 \cdot \frac{2}{3}\text{H}_2\text{O}$; the same hydrate is formed when crystals of the hexahydrate are allowed to stand in the mother-liquor at 20° to 25° . G. L. Clark and H. K. Buckner obtained the anhydrous carbonate by this procedure. H. St. C. Deville also obtained the *hexahydrate*, $\text{CoCO}_3 \cdot 6\text{H}_2\text{O}$, by keeping, in a sealed tube, a mixture of cobalt nitrate and of a soln. of sodium hydrocarbonate saturated with carbon dioxide; an amorphous precipitate is at first produced, but when exposed to a winter's cold, microscopic prisms appear. This hydrate does not change on exposure to air, but at a higher temp., passes into the tritadihydrate; and at 100° , both carbon dioxide and water are evolved. G. Cesaro said that the crystal plates are doubly refracting, and resemble those of stilbite (monoclinic).

Sphærocobaltite, anhydrous cobalt carbonate, occurs in small, spherical masses with a crystalline surface and a concentric, radiated structure. B. Üebler observed tree-like formations in slow precipitations. The colour is rose-red, altering superficially to a velvety black. The streak is peach-blossom red. H. de Sénarmont said that the artificial carbonate occurs as a red powder consisting of microscopic rhombohedra belonging to the trigonal system. A. Johnsen observed that the crystals are isomorphous with the magnesium, manganous, and ferrous carbonates. P. P. Ewald and C. Hermann referred the space-lattice of the rhombohedral crystals to that of the calcite type. A. Ferrari and C. Colla said that there are 4 mols. of CoCO_3 per unit cell, which has $a=5.91 \text{ \AA.}$, and $\alpha=103^\circ 22'$. M. Baccaredda gave for sphærocobaltite, $a=5.72 \text{ \AA.}$, and $\alpha=48^\circ 14'$, and 2 mols. of CoCO_3 per unit cell. A. Weisbach gave 4.02 to 4.13 for the sp. gr.; A. Lemke and W. Biltz, 4.124; and I. I. Saslawsky gave 4.0 to 4.13; and the value calculated by A. Ferrari and C. Colla from the lattice constants, is 4.24; and M. Baccaredda, 4.10. A. Lemke and W. Biltz, and I. I. Saslawsky discussed the vol. contraction which occurs during the formation of the salt from its elements. According to A. Weisbach, the hardness is 4.0. According to C. Winkler, the salt loses carbon dioxide when heated in air, and black cobaltosic oxide is formed. J. Krustinsons, A. A. Noyes and W. E. Vaughan studied the subject. F. de Carli gave for the dissociation press., p mm.:

	220°	258°	280°	318°
p	63.42	269.10	389.80	760.00

The calculated heat of dissociation is $\text{CoO} + \text{CO}_2 = \text{CoCO}_3 + 7.980 \text{ Cals.}$ The thermal decomposition was studied by B. Bruzs, and measurements of the rates of dissociation make it appear as if the decomposition occurs in two stages: $2\text{CoCO}_3 = \text{CoO} \cdot \text{CoCO}_3 + \text{CO}_2$, followed by $\text{CoO} \cdot \text{CoCO}_3 = 2\text{CoO} + \text{CO}_2$. M. le Blanc and E. Möbius observed that in a high vacuum, the thermal decomposition furnishes pure cobaltous oxide. F. de Carli calculated for the heat of formation ($\text{Co}, \text{C}, 1\frac{1}{2}\text{O}_2$) $=163.13$ to 173.31 Cals. ; $[\text{Co}(\text{OH})_2, \text{CO}_2 \text{ aq.}] = 10 \text{ Cals.}$; and $(\text{CoO}, \text{CO}_2) = 7.98 \text{ Cals.}$ E. Bertrand found that the birefringence is negative. There is a marked pleochroism—rose-red parallel to the principal axes, and violet-red when perpendicular to those axes. M. Kimura and M. Takewaki studied the transparency of the salt to ultra-violet rays. M. Trautz observed no crystalloluminescence, or triboluminescence. W. A. D. Rudge observed the spluttering of carbonate in the negative discharge. G. Wiedemann said that the carbonate is paramagnetic. When heated in the presence of oxygen, the carbonate is decomposed and cobaltosic oxide is formed (*q.v.*). R. Bernard and P. Job studied the oxidation of alkaline soln. in air. J. J. Berzelius observed that the carbonate is attacked by water, to form a basic carbonate. J. von Essen found that after cobalt carbonate had stood in contact with water at 15° for a month, 0.0273 grm. per litre passed into

soln., and at 100°, 0.0293 grm. per litre dissolved. Both W. J. Russell, and F. de Carli noted that cobalt carbonate is hydrolyzed by contact with water. G. Gore observed that liquefied hydrogen fluoride dissolves the carbonate with effervescence; and with liquid hydrogen chloride no perceptible evolution of gas occurs, and the liquid becomes a greenish-blue; whilst the residue becomes rose-red in air, and dissolves in dil. hydrochloric acid, without the evolution of gas. H. de Sénarmont observed that the crystalline powder is not attacked by conc. hydrochloric or nitric acids in the cold, and C. Winkler said that the action is very small, but when warmed, the carbonate dissolves, with the evolution of carbon dioxide. M. Kwiatnowsky recommended the carbonate as a reagent for detecting free hydrochloric acid in gastric juices. According to J. Gibson, when sodium carbonate is added in large excess to a soln. of a cobaltous salt, and the mixture shaken with a sufficient quantity of bromine, the whole of the precipitated cobaltous carbonate dissolves to a dark green soln., stable at ordinary temp., cobaltic oxide being precipitated on the addition of an aq. soln. of alkali hydroxide. If this green liquid is acidified with sulphurous acid, and the decolorized soln. be then oxidized, a red-coloured soln. is produced which absorbs oxygen from the air, and again becomes green. C. Dufraisse and D. Nakae studied the catalytic effect on the oxidation of soln. of sodium sulphite. G. Gore, and E. C. Franklin and C. A. Kraus found cobalt carbonate to be insoluble in liquid ammonia, and G. L. Clark, and G. L. Clark and H. K. Buckner reported that cobalt carbonate does not absorb dry ammonia; but it does dissolve in conc., aq. ammonia, and when the soln. is evaporated in vacuo, an unstable, hydrated **cobaltous amminocarbonate**, $\text{CoCO}_3 \cdot 3\text{NH}_3 \cdot 4\text{H}_2\text{O}$, is formed. L. Santi observed that cobalt carbonate is converted into the chloride when it is treated with an aq. soln. of ammonium carbonate, and ammonia and carbon dioxide are evolved; and by contact with solid ammonium chloride, or an aq. soln., the carbonate is converted into chloride. R. Salvadori noted that when cobalt dihydrazinechlorate is treated with carbon dioxide in the presence of an excess of hydrazine hydrate, **cobaltous trihydrazinecarbonate**, $\text{CoCO}_3 \cdot 3\text{N}_2\text{H}_4$, is formed. A. Naumann and J. Schröder, F. Schlegel, and A. Hantzsch observed that no change occurs when cobalt carbonate is heated with pyridine; N. A. Yajnik and F. C. Trehana, the photochemical reduction of sugars. C. Dufraisse and D. Nakae studied the catalytic effect on the oxidation of acetaldehyde, phenylaldehyde, purpuraldehyde, styrene, and turpentine. F. L. Cooper examined the absorption spectrum of soln. in acetic acid and sulphuric acid; A. Naumann and co-workers, that of cobalt carbonate dissolved in methyl acetate; S. U. Pickering, that it dissolves in tartaric, racemic, malic, and citric acids; L. I. Shaw, that the electrical conductivities of dimethyl sulphate, benzonitrole, aniline, amyl acetate, and salicylaldehyde are not altered by cobalt carbonate, but those of methyl alcohol, acetyl chloride, acetic anhydride, and epichlorhydrin are either increased or diminished; and I. I. Wanin and A. A. Tschernoyarova, that benzylidene chloride in an atm. of carbon dioxide at 60°, forms cobalt chloride and benzaldehyde. No definite product was obtained by P. N. Raikow in his study of the action of carbon dioxide on cobaltous hydroxide; but W. Beetz observed that hydrated cobaltous carbonate dissolves in water sat. with carbon dioxide, owing to the formation of an unstable **cobaltous hydrocarbonate**, $\text{Co}(\text{HCO}_3)_2$, when the aq. soln. is washed, cobaltous carbonate is deposited. G. Gore found that when 100 grms. of dry silica are added to 50 c.c. of a soln. containing 10 grms. of anhydrous cobalt carbonate, there is a rise of temp. of 0.21°.

As in the case of nickel carbonate, the salt is easily hydrolyzed by water, and a number of basic salts has been reported, several of which will be found to be arbitrarily selected stages in the hydrolysis of the salt.

W. Meigen treated a conc. soln. of cobalt nitrate with calcite and obtained **cobaltous hexahydroxycarbonate**, $\text{CoCO}_3 \cdot 3\text{Co}(\text{OH})_2$, or, according to A. Werner, $[\text{Co}(\text{HO})_2\text{Co}_3]\text{CO}_3$, as a blue precipitate; and by boiling a cobalt salt with an excess of sodium carbonate in an atm. of hydrogen for half an hour, he obtained the indigo-blue *monohydrate*. Sodium

carbonate is retained very tenaciously by the precipitate. Cobaltous salts in alkaline soln. are readily oxidized, so that W. Beetz reported that where the precipitate is boiled with water exposed to air, it becomes green, and develops chlorine when treated with hydrochloric acid. W. Meigen prepared **cobaltous tetrahydroxycarbonate**, $\text{CoCO}_3 \cdot 2\text{Co}(\text{OH})_2$, by treating a soln. of cobaltous nitrate with finely-powdered aragonite or calcite. With coarse fragments of calcite a mixture is produced. The product obtained with aragonite is said to resist attack by oxidizing agents better than the product with calcite. H. Rose described a *monohydrate* obtained by mixing boiling, dil. soln. of equimolar parts of cobalt sulphate and sodium carbonate, washing the violet precipitate with hot water, and drying it at 100° . W. Beetz treated a boiling soln. of a cobalt salt with the theoretical amount, or only a slight excess, of alkali carbonate, and obtained **cobaltous hexahydroxycarbonate**, $2\text{CoCO}_3 \cdot 3\text{Co}(\text{OH})_2 \cdot \text{H}_2\text{O}$, or, according to A. Werner, $[\text{Co}(\text{HO})_2\text{Co}]_3(\text{CO}_3)_2\text{Co}$, as a peach-blossom red precipitate, soluble in aq. soln. of ammonium, sodium, or potassium carbonate. If an excess of alkali carbonate is employed as precipitant, the precipitate is blue. W. Meigen observed that finely-divided aragonite gives, with a conc. soln. of cobalt nitrate, a lilac-coloured precipitate of this composition. The mol. of water is lost at 95° . If a soln. of cobalt chloride is used with aragonite or calcite, the precipitate has the same composition, but is contaminated with chlorine. W. Feitknecht said that the lattice has alternate layers of hydroxide and normal salt. Various kinds of precipitates obtained by G. C. Winkelblech, J. Setterberg, W. Beetz, W. Meigen, T. Nanty, C. D. Braun, F. Field, and H. Rose, had compositions ranging from CoO , 68.76 to 70.95; CO_2 , 14.11 to 17.00; and H_2O , 12.03 to 14.94 per cent.—the theoretical values for $2\text{CoCO}_3 \cdot 3\text{Co}(\text{OH})_2 \cdot \text{H}_2\text{O}$ are CoO , 70.05; CO_2 , 16.51; and H_2O , 13.44 per cent. N. A. Yajnik and F. C. Trehana studied the photosynthetic activity of cobalt carbonate in the reaction with carbon dioxide. W. Beetz reported **cobaltous dihydroxycarbonate**, $\text{CoCO}_3 \cdot \text{Co}(\text{OH})_2 \cdot 1\frac{1}{2}\text{H}_2\text{O}$, by the action of sodium hydrocarbonate on a soln. of a cobalt salt, when the product is treated, with water, particularly warm water, it passes into the hexahydroxycarbonate. T. Nanty obtained the *tetrahydrate*, $\text{CoCO}_3 \cdot \text{Co}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$. C. D. Braun also reported a lilac-red product approximating **cobaltous dihydroxycarbonate**, $2\text{CoCO}_3 \cdot \text{Co}(\text{OH})_2 \cdot 3\text{H}_2\text{O}$, which loses the whole of its water of hydration at 100° , and at 200° forms hydrated cobaltous oxide.

J. J. Berzelius noted that these basic carbonates are soluble in carbonic acid, in soln. of alkali hydrocarbonates, and ammonium carbonate; slightly soluble in conc. soln. of sodium or potassium carbonate, and in aq. ammonia. R. H. Brett noted the solubility of the basic carbonate in cold soln. of ammonium nitrate or chloride. V. Lenher and C. H. Kao observed that the basic carbonate is very little attacked by selenium monochloride; and E. C. C. Baly and co-workers, that the basic carbonate absorbs carbon dioxide, and acts catalytically in the synthesis of carbohydrates from carbon dioxide and moisture. J. Spiller observed that the cobalt carbonates are not precipitated from soln. containing sodium citrate.

According to J. L. Proust, cobalt carbonate is soluble in aq. ammonia, or ammonium carbonate, and cobaltous hydroxide is soluble in a soln. of ammonium carbonate. The soln. are readily oxidized, and in air, a carmine-red liquid is produced which deposits crystals of cobalt carbonate. H. St. C. Deville obtained **ammonium cobaltous carbonate**, $2(\text{NH}_4)_2\text{CO}_3 \cdot \text{CoCO}_3 \cdot 4\text{H}_2\text{O}$, by adding ammonium carbonate to a soln. of cobalt nitrate, and allowing the mixture to stand. The red-currant coloured, prismatic crystals are stable in air at low temp. In addition to the *tetrahydrate*, the *enneahydrate*, $2(\text{NH}_4)_2\text{CO}_3 \cdot \text{CoCO}_3 \cdot 9\text{H}_2\text{O}$, and the *dodecahydrate*, $2(\text{NH}_4)_2\text{CO}_3 \cdot \text{CoCO}_3 \cdot 12\text{H}_2\text{O}$, were prepared. If ammonium hydrocarbonate, at 15° to 18° , be added to a soln. of cobalt nitrate, rose-red, micaceous crystals of **ammonium cobaltous hydrocarbonate**, $\text{NH}_4(\text{HCO}_3) \cdot \text{CoCO}_3 \cdot 4\text{H}_2\text{O}$, are formed, and in air, the crystals of the *tetrahydrate* lose ammonia and furnish a brown powder. By working at 0° , rose-red, micaceous plates of the *hemienneahydrate* are formed.

According to J. J. Berzelius, molten sodium carbonate dissolves a little cobalt oxide. When an excess of sodium carbonate is added to a soln. of a cobaltous salt, the red precipitate first formed dissolves so as to produce a red soln. According to H. St. C. Deville, if precipitated cobalt carbonate be allowed to stand under a soln. of sodium hydrocarbonate, the amorphous solid retains sodium very tenaciously, but no compound is formed. If a soln. of cobaltous nitrate be treated with the sodium hydrocarbonate, $\text{Na}_2\text{CO}_3 \cdot 2\text{NaHCO}_3$, carmine-red, monoclinic crystals

of **sodium cobaltous carbonate**, $\text{Na}_2\text{CO}_3 \cdot \text{CoCO}_3 \cdot 4\text{H}_2\text{O}$, are formed with the axial ratios $a : b : c = 1.2295 : 1 : 1.0958$, and $\beta = 114^\circ 8'$. M. P. Applebey and K. W. Lane obtained the tetrahydrate by heating at 50° a soln. of cobalt nitrate in a soln. of 100 grms. of sodium carbonate and 40 grms. of sodium hydrocarbonate per litre, and it can be re-crystallized from a soln. of these two sodium carbonates. F. de Carli obtained this carbonate mixed with a basic carbonate, by the action of a conc. of sodium carbonate on cobalt nitrate. The *tetrahydrate* is decomposed by water, and when heated, it loses water and carbon dioxide without melting. With more conc. soln., the *decahydrate*, $\text{Na}_2\text{CO}_3 \cdot \text{CoCO}_3 \cdot 10\text{H}_2\text{O}$, is formed. The colour is rather deeper than is that of the tetrahydrate. This salt loses some water in vacuo. C. Duval obtained **sodium cobalt percarbonate**, possibly $\text{Na}[\text{CoCO}_4]$, by the action of ozone on a mixed soln. of a cobaltous salt and sodium carbonate.

J. J. Berzelius observed that cobalt oxide dissolves freely in molten potassium carbonate; and J. L. Proust, that cobalt hydroxide and carbonate, but not the ignited oxide, form red soln. with a conc. soln. of potassium carbonate, and the solute is not precipitated by heat, but it is precipitated by dilution with water. H. St. C. Deville prepared quadratic prisms of **potassium cobaltous carbonate**, $\text{K}_2\text{CO}_3 \cdot \text{CoCO}_3 \cdot 4\text{H}_2\text{O}$, by adding the potassium hydrocarbonate, $\text{K}_2\text{CO}_3 \cdot 2\text{KHCO}_3$, to a soln. of cobalt nitrate; and W. C. Reynolds, by cooling a warm soln. of a cobalt salt and potassium carbonate.

FIG. 141.—The Dissociation of Potassium Cobaltous Carbonate.

T. B. Wood and H. O. Jones obtained the tetrahydrate by adding potassium carbonate to a soln. of cobaltous chloride, and shaking the precipitate until it again dissolves; or making a soln. of 4 c.c. of a sat. soln. of cobalt chloride in 50 c.c. of a soln. of potassium carbonate (with 100 grms. of carbonate per 100 grms. of water). The soln. deposits crystals of the tetrahydrate. M. P. Applebey and K. W. Lane said that the salt exists only in presence of HCO_3^- ions, and treated a soln. of cobalt nitrate with a soln. of 400 grms. of potassium carbonate and 100 grms. of potassium hydrocarbonate per litre. The salt can be re-crystallized from a soln. of these two potassium carbonates.

The six-sided, rose-coloured prisms of the *tetrahydrate* are isomorphous with those of the corresponding nickel salt. F. de Carli studied the thermal dissociation of the carbonate, and found that the salt can be dehydrated at 100° to 120° , in a current of carbon dioxide, to furnish the deep violet, anhydrous salt. The dissociation press. is 63.42 mm. at 220° ; 389.80 mm. at 280° ; and 760 mm. at 318° , Fig. 141; and the heat of dissociation is 13.74 Cals., as in the case of the cobaltous carbonate. The heat of formation of the anhydrous carbonate from its elements is 460.17 Cals., $(\text{CoCO}_3, \text{K}_2\text{CO}_3) = 5.76$ Cals.; and $\text{K}_2\text{CO}_3 \cdot \text{CoCO}_3 + 4\text{HCl} = 2\text{KCl} + \text{CoCl}_2 + 2\text{CO}_2 + 2\text{H}_2\text{O} + 17.75$ Cals. The heat of hydration to the tetrahydrate is 11.37 Cals. M. P. Applebey and K. W. Lane observed that at ordinary temp., the carbonate is stable; and it is decomposed by water; but T. B. Wood and H. O. Jones said that the aq. soln. is stable when heated, and that the colour changes from rose-red to blue. T. B. Wood and H. O. Jones said that the aq. soln. of the salt does not give any precipitate on boiling, but it becomes blue and returns to the original pink colour on cooling. From the behaviour of the soln. on electrolysis, it is probable that a pink complex $\text{Co}(\text{CO}_3)_2^{--}$ ion is present. T. Nanty obtained a crystalline **potassium cobaltous hydrocarbonate**, $\text{KHCO}_3 \cdot \text{CoCO}_3 \cdot 4\text{H}_2\text{O}$; cobaltous carbonate does not combine directly with potassium hydrocarbonate, and no equilibrium was observed in the action of water on the double carbonate. H. Rose, and H. St. C. Deville obtained this hydrocarbonate by adding an excess of potassium hydrocarbonate, $\text{K}_2\text{CO}_3 \cdot 2\text{KHCO}_3$, to a soln. of cobalt nitrate. The rose-red crystals effloresce in air, and are decomposed by water. T. Nanty said that the rose-red

crystals are isomorphous with those of the corresponding magnesium and nickel salts. When heated, the colour becomes violet as carbon dioxide and water are evolved. When heated in nitrogen, cobalt dioxide is formed; and water decomposes the salt.

G. A. Bilibin described a cobaltiferous smithsonite—**cobaltsmithsonite**—or **cobaltous zinc carbonate**, $(\text{Co}, \text{Zn})\text{CO}_3$, from Boles, Lower California. A. Ferrari and R. Santucci obtained **cobaltous cadmium carbonates**, $\text{Co}_3\text{Cd}(\text{CO}_3)_4$, $\text{CoCd}(\text{CO}_3)_2$, and $\text{CoCd}_3(\text{CO}_3)_4$; as well as corresponding **cobaltous manganous carbonates**.

§ 26. Cobaltic Carbonate and its Complex Salts

W. Beetz¹ observed that a green cobaltic carbonate is produced by the oxidation of cobaltous carbonate. In 1862, F. Field observed that when cobaltous nitrate is added to a soln. of sodium hydrocarbonate containing a small proportion of sodium

hypochlorite, an intense green soln. is produced without the evolution of carbon dioxide. J. Gibson found that the same green colour is produced by bromine in the presence of sodium carbonate; N. C. Nag said that the green soln. so obtained gives a precipitate when shaken with alcohol and ether, and added that the precipitate is free from bromine, and it is very unstable. It was thought to be an oxidation product analogous to the ferrates. A. Job determined the atomic ratio of cobalt to oxygen in the green soln. to be $\text{Co} : \text{O} = 2 : 3$ in agreement with the assumption that a cobaltic salt is present.

A. H. McConnell and E. S. Hanes showed that the green soln. contains alkali percobaltites, where cobalt dioxide takes the place of MnO_2 in the permanganites. This conclusion is based on the observed atomic proportions $\text{K} : \text{Co} = 2 : 1$; and because an acidic reaction was obtained with the colourless filtrate from a mixture of cobaltous hydroxide and hydrogen dioxide, the colourless soln. was assumed to contain *percobaltous acid*, H_2CoO_3 . R. G. Durrant, however, observed no acidic reaction when purified hydrogen dioxide was employed. A. Metzl also found that in the moist state, the green precipitate obtained when hydrogen dioxide is added to a cobaltous salt in the presence of sodium hydrocarbonate, has the composition, $\text{CoCoO}_3 \cdot \text{CoCO}_3$, indicating that it is a mixture of *cobaltous cobaltite* and cobaltous carbonate. It is partly decomposed by washing with alcohol and ether.

The preparation of the cobaltic carbonate by treating cobaltous salt soln. with oxidizing agents—hydrogen dioxide, chlorine or bromine, or alkali hypochlorite—was also described by A. H. McConnell and E. S. Hanes, A. Job, H. Copaux, and C. C. Palit. C. Duval used ozone as oxidizing agent; H. C. Byers electrolyzed a soln. of sodium hydrocarbonate with cobalt anodes; and G. A. Barbieri treated an alkali cobaltic nitrite with sodium hydrocarbonate—normal sodium carbonate produces hydrated cobaltic oxide—and the presence of HCO_3^- ions are, therefore, necessary for the production of cobaltic carbonate. E. Birk obtained the solid by the action of a soln. of sodium or ammonium carbonate on cobaltic fluoride, $\text{Co}_2\text{F}_6 \cdot 7\text{H}_2\text{O}$; and C. Duval by the following process:

A conc., aq. soln. of 5 grms. of cobaltous carbonate was mixed, in the dark, with a conc. soln. of 8 grms. of sodium hydrocarbonate, 50 c.c. of 100 per cent. of hydrogen dioxide, and 100 grms. of an aq. soln. of glycerol of sp. gr. 1.262, with constant stirring in order to remove sodium carbonate. The olive-green powder has the composition $\text{Co}_2(\text{CO}_3)_3$, or $\text{Co}[(\text{CO}_3)_3]$, and it is filtered off, and washed with absolute alcohol. It is sensitive to light, and can be preserved in darkness.

R. G. Durrant obtained a green soln. on adding hydrogen dioxide to soln. of cobaltous salts in the presence of alkali hydrocarbonates, and suggested that a *cobaltic acid*, H_2CoO_4 , is formed, because each atom of oxygen spent in oxidizing 2 atoms of cobalt, disengages two mols. of carbon dioxide. The observed results agree with the equation: $4\text{KHCO}_3 + 2\text{CoCO}_3 + \text{H}_2\text{O}_2 = [\text{Co}(\text{KCO}_3)_2]_2\text{O} + 2\text{CO}_2 + 3\text{H}_2\text{O}$. He also observed that green soln. and green precipitates were obtained by the use of various oxidizing agents in the presence of the hydrocarbonate, and concluded that the green soln. contained **cobaltic carbonate**, $\text{Co}_2(\text{CO}_3)_3$, and that the precipitate, which was fairly stable in an atm. of carbon dioxide, may be cobaltic carbonate itself.

N. C. Nag assumed that the cobalt is sexivalent; A. H. McConnell and E. S. Hanes, and A. Metzl, quadrivalent; and A. Job, R. G. Durrant, G. Barbieri, and R. Bernard and P. Job, trivalent, or a mixture of trivalent and quadrivalent. R. Bernard and P. Job, and R. G. Durrant studied the absorption spectrum of the soln.; and C. Duval, and G. A. Barbieri, the transport numbers. R. G. Durrant found that cobaltous oxide and salts form double salts with carboxylic acids—e.g., acetic, tartaric, citric, oxalic, lactic, malic, succinic, and glycollic acids—and on oxidation, green compounds are formed whose stability is increased by the presence of an excess of the alkali salt. The results indicate that a complex salt containing trivalent cobalt, $:\text{Co.O.Co}:$, is present, so that

in the case of the hydrocarbonate soln., the complex salt is probably **potassium cobaltic carbonate**, $[\text{Co}(\text{KCO}_3)_2]_2\text{O}$, or :

but no evidence of such a product was observed in the case of the normal carbonates. The green colour of these soln. is characteristic of cobaltic combinations with the carboxylic acids, and this, in turn, depends on the presence of complex ions containing the nucleus : Co.O.Co : . These conclusions are also in agreement with the absorption spectra of the soln.

O. W. Gibbs and F. A. Genth² prepared **cobaltic hexamminocarbonate**, $[\text{Co}(\text{NH}_3)_6]_2(\text{CO}_3)_3 \cdot 7\text{H}_2\text{O}$, by treating the corresponding chloride with the theoretical proportion of silver carbonate, and evaporating the yellow filtrate. The brownish-yellow, rhombic prisms of the *heptahydrate* may contain some acid carbonate, owing to the absorption of carbon dioxide from air. J. D. Dana said that the rhombic prisms have the axial ratios $a : b : c = 0.6148 : 1 : 0.6460$. F. M. Jäger regarded the salt as a *hexahydrate*. Observations were also made by A. Dubosc, and L. Jacobsen. When the salt is dried in air, O. W. Gibbs and F. A. Genth observed that some water is given off, and the crystals become opaque. The salt is readily dissolved by hot water. By passing carbon dioxide into a soln. of the carbonate, brownish-red or brownish-yellow, monoclinic prisms of **cobaltic hexamminohydrocarbonate**, $[\text{Co}(\text{NH}_3)_6](\text{HCO}_3)\text{CO}_3 \cdot 2\frac{1}{2}\text{H}_2\text{O}$, were formed. J. D. Dana, and F. M. Jäger gave for the axial ratios $a : b : c = 1.131 : 1 : 0.819$, and $\beta = 71^\circ 44'$. The salt does not lose its water of hydration in air, but it does so in vacuo ; it is less soluble than the normal carbonate. L. Jacobsen obtained **cobaltic hexamminochlorocarbonate**, $[\text{Co}(\text{NH}_3)_6](\text{CO}_3)\text{Cl}$, from a mixture of sat. soln. of the chloride and carbonate, or by treating the chloride with potassium carbonate, and crystallizing from boiling water.

F. Claudet, and S. M. Jörgensen prepared **cobaltic aquopentamminocarbonate**, in aq. soln., by rubbing up the chloropentamminochloride, or bromopentamminobromide, with the theoretical proportion of silver carbonate, and a little water. It is also formed by the action of carbon dioxide on an aq. soln. of aquopentamminohydroxide. The red liquid has a strong alkaline reaction.

G. Vortmann and O. Blasberg described **cobaltic nitratopentamminocarbonate**, but A. Werner and N. Goslings showed that the product is really carbonatopentamminonitrate—*vide infra*. S. M. Jörgensen reported **cobaltic chloropentamminocarbonate**, $[\text{Co}(\text{NH}_3)_5\text{Cl}](\text{CO}_3) \cdot 4\frac{1}{2}\text{H}_2\text{O}$, to be formed by triturating the corresponding chloride with silver carbonate and a little water, and adding alcohol to the filtrate. The work must be done rapidly, or the aquopentammino-salt may be formed. The violet-red crystals of the *hemihydrate* are freely soluble in water, and the soln. has an alkaline reaction. The crystals lose nearly all their water of hydration on exposure to air ; an aq. soln. of the weathered salt, on treatment with alcohol, gave dark violet prisms of a *hemihydrate*.

A. Werner reported **cobaltic hydrocarbonatopentamminobromide**, $[\text{Co}(\text{NH}_3)_5(\text{HCO}_3)]\text{Br}_2$, to be formed, as a violet-red powder consisting of fine needles, by passing carbon dioxide into a conc. soln. of hydroxy-bromide ; and **cobaltic hydrocarbonatopentamminiodide**, $[\text{Co}(\text{NH}_3)_5(\text{HCO}_3)]\text{I}_3$, by passing carbon dioxide through an aq. soln. of the hydroxy-nitrate. The pale carmine-red, microscopic crystals are stable in air. They are sparingly soluble in water, and the soln. has an alkaline reaction. The cold, aq. soln. is stable, but when warmed, carbon dioxide escapes and the soln. reverts to the hydroxy-nitrate. Potassium iodide precipitates a polyiodide ; and with 20 per cent. aq. ammonia, carbonatopentamminonitrate is formed. J. Kranig prepared **cobaltic carbonatopentamminochloride**, $[\text{Co}(\text{NH}_3)_5(\text{CO}_3)]\text{Cl} \cdot \text{H}_2\text{O}$; and W. Kuhn and K. Bein studied the absorption spectrum. N. Goslings prepared **cobaltic carbonatopent-**

aminobromide, $[\text{Co}(\text{NH}_3)_5\text{CO}_3]\text{Br}$, and **cobaltic carbonatopentamminoiodide**, $[\text{Co}(\text{NH}_3)_5\text{CO}_3]\text{I}$.

G. Vortmann and O. Blasberg described a **cobaltic sulphatopentamminocarbonate**, but J. Kranig showed that the product is rather **cobaltic carbonatopentamminosulphate**, $\{[\text{Co}(\text{NH}_3)_5]_2(\text{CO}_3)\}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$. It was obtained by the aerial oxidation of a cold soln. of cobaltous sulphate in aq. ammonia and ammonium carbonate. When alcohol is added to the soln., an oily liquid is precipitated, and this, with more alcohol, crystallizes. The crystals are unstable, and deliquesce in moist air. The air-dried *tetrahydrate* loses about $1\frac{1}{2}\text{H}_2\text{O}$ over calcium chloride, and the remainder is lost at 75° , the salt decomposes at a higher temp. It is readily soluble in water.

G. Vortmann³ obtained **cobaltic carbonatotetramminocarbonate**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]_2\text{CO}_3 \cdot 3\text{H}_2\text{O}$, from the mother-liquor left in the preparation of the hydrocarbonate; and S. M. Jörgensen, by triturating the iodide with freshly-precipitated silver carbonate and water, and precipitating from the filtrate with alcohol. The violet, rhombic plates of the *trihydrate* lose 3 mols. of water over sulphuric acid, and take them up again when exposed to moist air. The salt decomposes at 100° . The salt is readily soluble in water, and the soln. has an alkaline reaction; only one-third of the total carbonate is ionogenic. Sodium dithionate precipitates the salt almost completely from aq. soln. K. Tschibisoff and co-workers studied the reactions of this salt. When the aq. soln. is saturated with carbon dioxide, and alcohol is added, **cobaltic carbonatotetramminohydrocarbonate**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{HCO}_3 \cdot \text{H}_2\text{O}$, is formed. G. Vortmann obtained this salt by oxidizing a conc. ammoniacal soln. of cobaltous carbonate, saturating the liquid with carbon dioxide, and precipitating the salt with alcohol. A. Miolati said that in attempting to prepare the corresponding thiocyanate by adding barium thiocyanate to a soln. of cobaltous sulphate, treating the filtrate with ammonia and ammonium carbonate, and passing a current of air through the liquid, he obtained a red precipitate of the carbonato-hydrocarbonate, since that salt is less soluble than the carbonato-thiocyanate. The red, prismatic crystals of the *monohydrate* were found by A. Miolati to decompose slowly at the temp. of the water-bath, losing more in weight than corresponds with the water of hydration. S. M. Jörgensen also noted that the salt decomposes at 100° ; and that when treated with hydrochloric acid, a cold, aq. soln. furnishes the diaquotetramminochloride, and a hot soln., the chloroaquotetramminochloride. A. Miolati found that the mol. electrical conductivities of soln. of a mol. of the salt in 32 and 1024 litres are, respectively, 59.45 and 79.18; and at infinite dilution, 82.6. It is hence inferred that hydrolysis does not occur, in aq. soln. that the soln. contains a salt of a dibasic acid with a univalent base, possibly **cobaltic carbonatotetramminopyrocarbonate**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]_2(\text{CO}_2)_2\text{O}$. G. Vortmann reported a basic salt, **cobaltic carbonatohydroxyaquotriamminohydroxide**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})(\text{CO}_3)]\text{OH} \cdot \frac{1}{2}\text{H}_2\text{O}$, to be formed in preparing the carbonatotetramminocarbonate. It is precipitated by alcohol as an oil which, by repeated solution, and treatment with alcohol, ultimately crystallizes. R. Uehleke measured the magnetic rotation of the plane of polarization of light in soln. of the salt. A. B. Lamb and V. Yngve found that **cobaltic carbonatotetramminohydroxide** exists only in aq. soln. The mol. conductivities of soln. with 0.2683 and 33.32 mols per litre at 0° , are, respectively, 100.3 and 108.7—or, at the limit, 121.8—and the percentage ionization in these two soln. are, respectively, 85.3 and 89.2. J. Meyer prepared **cobaltic carbonatotetramminomethylsulphate**, $[\text{Co}(\text{NH}_3)_4\text{CO}_3]\text{CH}_3 \cdot \text{SO}_4$.

A. Miolati reported the preparation of **cobaltic carbonatotetramminofluoride**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{F} \cdot 3\text{H}_2\text{O}$. S. M. Jörgensen, and G. Vortmann and O. Blasberg prepared **cobaltic carbonatotetramminochloride**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{Cl}$, by passing air, for 2 or 3 hrs., through a soln. of cobaltous chloride, and ammonium carbonate in conc. ammonia, and adding alcohol; also by adding alcohol to a soln. of the nitrate in conc. soln. of ammonium carbonate—*vide infra*, the nitrate; and by

trituration freshly-precipitated silver chloride with the corresponding iodide. The rhombic plates first formed pass into four-sided and six-sided prisms when kept under the mother-liquor. The salt loses only a trace of water when confined over sulphuric acid; and it is decomposed at 100° . G. Vortmann and O. Blasberg supposed the salt to be a hemitrihydrate. E. Valla, Y. Shibata, and Y. Shibata and G. Urbain studied the absorption spectra of aq. soln. N. R. Dhar and G. Urbain measured the polarization tension—*vide supra*, the hexamminochloride. R. Schwarz and K. Tede noted that the soln. decomposes in ultra-violet rays. A. Werner found that alcoholic hydrogen chloride changes the salt into cis-dichlorotetramminochloride; and W. Schramm found that oxalic acid converts it into the oxalato-chloride, and warm malonic acid (below 65°) forms malonato-chloride. The general reactions are like those of the nitrate. S. M. Jörgensen observed that sodium chloroaurate precipitates from a soln. of the corresponding nitrate, **gold cobaltic carbonatotetramminochloride**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)](\text{AuCl}_4) \cdot \frac{1}{2}\text{H}_2\text{O}$, in brownish-red, rhomboidal plates or needles which are dehydrated at 100° . The salt is sparingly soluble in water; insoluble in alcohol.

S. M. Jörgensen prepared **cobaltic carbonatotetramminobromide**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{Br}$, by a process analogous to that employed for the chloride. It loses no weight over sulphuric acid; and slowly decomposes at 100° . A. Uspensky and K. Tschibisoff studied the absorption spectrum; F. de Boer, the X-ray absorption spectrum; and A. Werner and A. Miolati, the mol. conductivity at 25° . E. Petersen found the mol. conductivities of soln. of a mol of the salt in 50, 2000, and 3200 litres of water were, respectively, 52.8, 59.2, and 70.7 at 0° , and 96.4, 104.3, and 131.3 at 25° . The subject was discussed by A. Werner and C. Herty, and by W. D. Harkins and co-workers. W. Schramm found that oxalic acid reacts forming the oxalato-bromide; and warm malonic acid, the malonato-bromide.

S. M. Jörgensen prepared **cobaltic carbonatohexamminiodide**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{I}$, in brownish-violet needles, by a process analogous to that employed for the chloride. A. Uspensky and K. Tschibisoff studied the absorption spectrum. W. Schramm found that the salt is reduced to the cobaltous state by warm oxalic and malonic acids. F. Ephraim and P. Mosimann obtained **cobaltic carbonatotetrammino-triiodide**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{I}_3$, as a black aggregate of crystals, by the action of a soln. of iodine and potassium iodide on the corresponding nitrate. The salt decomposes at 140° . They also prepared **mercuric cobaltic carbonatopentamminiodide**, $2[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{I} \cdot \text{HgI}_2$, as a bluish-red precipitate, by adding alcohol to a soln. of the corresponding nitrate and potassium chloromercurate; and **bismuth cobaltic carbonatotetramminiodide**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{I} \cdot \text{BiI}_3$, as a reddish-yellow precipitate, by adding bismuth iodide to a soln. of the iodide.

G. Vortmann, R. Pers, and G. Vortmann and O. Blasberg prepared **cobaltic carbonatotetramminosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$; and S. M. Jörgensen recommended adding a soln. of cobaltous carbonate (20 grms.) in dil. sulphuric acid to a soln. of ammonium carbonate (100 grms.) in 250 c.c. of conc., aq. ammonia, passing a current of air through the liquid for 2 or 3 hrs. and evaporating the soln. with the addition of ammonium carbonate from time to time—*vide infra*, the nitrate. A. Uspensky and K. Tschibisoff obtained it by passing carbon dioxide into an aq. soln. of diaquotetramminosulphate, in the presence of calcium carbonate. The garnet-red prisms of the *trihydrate* were found by F. M. Jäger to be rhombic bipyramids with the axial ratios $a : b : c = 2.2212 : 1 : 1.8003$, sp. gr. 1.807 at 20° ; mol. vol. 290.0; and topic axial ratios $\chi : \psi : \omega = 9.2630 : 4.1702 : 7.5075$. On the other hand, L. W. Strock found the crystals to be monoclinic hemihedral, with the axial ratios $a : b : c = 1.1132 : 1 : 0.7030$, and $\beta = 98^{\circ} 39'$. There are three prominent cleavages parallel to the (100)-, (010)-, and the (102)-faces. The first is perfect, the other two are good. The ruby-red crystals are strongly pleochroic—the colour parallel to (100) is purple-red; that parallel to (010) is brownish-red

with a purple tinge; and that parallel to (001) is brownish-red. The index of refraction for the 670.2μ ray is 1.6221; for the 658μ ray, 1.6240; for the 610μ ray, 1.6284; and for the 589μ ray, 1.6320; for the 670.2μ ray, $\alpha=1.5973$, $\beta=1.6210$, and $\gamma=1.6221$; and for the 589μ ray, $\alpha=1.5949$, $\beta=1.6309$, and $\gamma=1.6320$. The X-radiograms correspond with a unit cell having $a=11.80$ A., $b=10.60$ A., and $c=7.12$ A.; and $\beta=98^\circ 39'$, which accommodates 2 mols. of the salt of sp. gr. 1.8816 at 22° .

A. Benrath and W. Kohlberg observed an abrupt change in the curve representing the vap. press. and the mol. proportion of water, corresponding with the trihydrate. A. Gordienko, and A. Uspensky and K. Tschibisoff studied the absorption spectra of aq. soln.; and F. de Boer, the X-ray absorption spectra. K. Matsuno found the mol. conductivities of soln. with a mol of the salt in 100, 400, and 1600 litres at 25° , were, respectively, 78.83, 92.13, and 106.2. R. Schwarz and K. Tede observed that aq. solution occurs with soln. in the ultra-violet rays. L. W. Strock and T. P. McCutcheon observed that 100 c.c. of sat. soln. at 25° contained 6.061 grms. of the carbonato-sulphate. W. von Behren and I. Traube studied the subject. S. M. Jørgensen, and K. J. Pedersen measured the rate of decomposition of the salt. F. Ephraim found that dil. sulphuric acid converts the salt into the diaquo-sulphate, with the evolution of carbon dioxide. K. Matsuno studied the flocculating action on the hydrosol of arsenic sulphide. W. Schramm found that oxalic acid converts it into the oxalato-sulphate; and malonic acid, into the malonato-sulphate. The general reactions are like those of the nitrate.

G. Vortmann and O. Blasberg, and S. M. Jørgensen prepared **cobaltic carbonato-tetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{NO}_3 \cdot \frac{1}{2}\text{H}_2\text{O}$, by the method analogous to that employed for the chloride and sulphate. H. and W. Biltz recommended the following process:

A soln. of 100 grms. of ammonium carbonate in 500 c.c. of water in a litre flask is mixed with 250 c.c. of conc., aq. ammonia, and then with a soln. of 20 grms. of cobalt carbonate in as little conc. nitric acid as possible, and diluted to 100 c.c. A vigorous current of air is then drawn through the liquid for 3 hrs. The colour of the liquid changes from deep violet to blood-red. The soln. is concentrated to about 300 c.c. in a porcelain dish, 5 grms. of powdered ammonium carbonate are added every 15 minutes—making about 25 grms. in all. The filtered soln. is boiled down to about 200 c.c. with the continued addition, in small lots at a time, of about 10 grms. of ammonium carbonate. The crystals which separate from the cooling soln. are washed first with a little water, then with dil. alcohol, and finally with alcohol alone. An impure crop of crystals can be collected by concentrating the mother-liquor; extracting the product at room temp., with 15 times its weight of water, precipitating the salt from the filtered soln. by adding 2 or 3 vols. of alcohol, and treating the precipitate as before. Yield, 22 to 25 grms.

The carmine-red, rhombic plates of the hemihydrate, according to S. M. Jørgensen, lose their water of hydration at 100° , and they take up the water again on exposure to moist air. A. Benrath and K. Andreas considered the salt to be the *monohydrate*. A. Uspensky and K. Tschibisoff measured the absorption spectrum; and F. de Boer, the X-ray absorption spectrum. Measurements of the electrical conductivity of aq. soln. by A. Werner and A. Miolati, and N. R. Dhar show that the salt is not stable in aq. soln. at 25° to 30° . H. Freundlich and G. Ettisch studied the electrokinetic potential. S. Berkman and H. Zocher found the magnetic susceptibility to be 0.22×10^{-6} mass unit; and the magnetic properties were studied by W. Biltz, and G. Depold. S. M. Jørgensen observed that 100 grms. of water dissolve 6.67 grms. of the salt. A conc., aq. soln. is deep red, and it gives precipitates with sodium dithionate, chloroaurate, or chloroplatinate; and with potassium iodide, or chloroplatinite. K. Matsuno studied the flocculating action on arsenic sulphide. F. Ephraim observed that precipitates are formed with nitronaphthalene- β -sulphonic acid, and with dinitro-6-chlorobenzene-5-sulphonic acid. W. Schramm noted that oxalic acid yields the oxalato-nitrate, and warm malonic acid, the malonatonic nitrate.

A. Werner prepared a soln. of **cobaltic carbonatobisethylenediaminehydroxide**, $[\text{Co en}_2(\text{CO}_3)]\text{OH}$, by treating a soln. of the corresponding bromide with freshly-precipitated

silver oxide; and although the salt could not be isolated, the soln. was found by A. Werner, J. C. Duff, and T. S. Price and S. A. Brazier to be useful for building up complexes with dibasic organic acid radicles in the inner complex.

A. Werner and J. Rapiort, H. Seibt, H. E. Watts, E. Schmidt, and W. Tupizina prepared **cobaltic carbonatobisethylenediaminechloride**, $[\text{Co en}_2(\text{CO}_3)]\text{Cl} \cdot \text{H}_2\text{O}$, by heating trans-dichlorobisethylenediaminechloride with the theoretical proportion of sodium carbonate in aq. soln. The deep red soln. deposits dark red crystals of the *monohydrate*. The salt loses the water of hydration at 70° to 80° . The anhydrous salt was also prepared by J. Meisenheimer and co-workers. The absorption spectra of aq. soln. were studied by J. Angerstein, Y. Shibata, and K. Matsuno. W. Schramm found that with oxalic acid, the oxalato-chloride, and with malonic acid, probably, malonato-chloride are formed. A. Werner and T. P. McCutcheon treated the optically active dichloro-chlorides in a similar manner, and obtained red, crystalline powders of the *dextro-salt* and the *levo-salt*. The sp. rotation of 0.2 per cent. aq. soln. were $[\alpha] = \pm 350^\circ$. The soln. at 90° becomes inactive; and the activity of the soln. which has been kept for 14 days at ordinary temp., is about half its original value. K. Tschibisoff and co-workers studied these salts. J. C. Dippel and F. M. Jäger prepared **cobaltic carbonatobisdiaminotetrammino-chloride**, $[\text{Co ptn}_2\text{CO}_3]\text{Cl}$, with $\alpha\beta\delta$ - and $\beta\beta\delta$ -diaminopentanes.

A. Werner and J. Bösshart prepared **cobaltic carbonatobisethylenediaminebromide**, $[\text{Co en}_2(\text{CO}_3)]\text{Br}$, by the action of carbon dioxide on an aq. alkaline ice-cold soln. of cis- or trans-hydroxyaquobisethylenediaminebromide; and by A. Werner and J. Rapiort, and P. Pfeiffer and O. Angern, by the action of potassium bromide on the corresponding chloride. The salt crystallizes from its aq. soln. partly as a hydrate in dark red, hexagonal prisms, and partly as a brownish-red, crystalline crust. The hydrated form loses its combined water in air. The absorption spectra of aq. soln. were studied by A. Gordienko, and J. Angerstein. J. C. Duff found the mol. conductivities of soln. with a mol of the salt in 32, 256, and 1024 litres of water, at 25° , to be, respectively, 90.46, 103.5, and 106.1. E. Schmidt, and A. Werner and J. Rapiort prepared **cobaltic carbonatobisethylenediamineiodide**, $[\text{Co en}_2(\text{CO}_3)]\text{I}$, by the action of potassium iodide on the corresponding chloride. The dark red, prismatic crystals are sparingly soluble in water, since 100 grms. of water at 80° dissolve 1.43 grms. of the iodide. J. Angerstein, and Y. Shibata studied the absorption spectra of aq. soln. A. Werner and J. Rapiort obtained the optically active *dextro-salt*, and *levo-salt*, in a similar way, by starting from the corresponding optically active chlorides. The sp. rotations of 0.2 per cent. aq. soln. were $[\alpha] = \pm 250^\circ$. G. and P. Spacu prepared **silver cobaltic carbonatobisethylenediamineiodide**, $[\text{Co en}_2(\text{CO}_3)]\text{AgI}_2$; and **mercury cobaltic carbonatobisethylenediamineiodide**, $[\text{Co en}_2\text{CO}_3]\text{HgI}_2$.

A. Werner and J. Rapiort prepared **cobaltic carbonatobisethylenediaminesulphate**, $[\text{Co en}_2(\text{CO}_3)]_2\text{SO}_4 \cdot 5\text{H}_2\text{O}$, by the action of a soln. of silver sulphate on a cold, sat. soln. of the iodide. The black, prismatic crystals of the *pentahydrate* become anhydrous at 100° . Silver nitrate acting on the bromide of the series, furnishes **cobaltic carbonatobisethylenediaminenitrate**, $[\text{Co en}_2(\text{CO}_3)]\text{NO}_3 \cdot \text{H}_2\text{O}$; and P. Pfeiffer and O. Angern obtained the same salt by the action of potassium carbonate on a soln. of the trans-dichloronitrate, on a water-bath, and subsequently cooling the red liquid on ice. The bluish-red needles are soluble in water. A. Werner and J. Rapiort found that 100 grms. of water dissolve 5 grms. of the salt at 60° . J. Angerstein, and Y. Shibata studied the absorption spectra of aq. soln. J. Kranig obtained **cobaltic carbonatodecamminosulphate**, $[\text{Co}_2(\text{NH}_3)_{10}\text{CO}_3](\text{SO}_4) \cdot 4\text{H}_2\text{O}$.

A. Werner prepared **cobaltic carbonatobis(trimethylenediamine)chloride**, $[\text{Co}(\text{NH}_2\text{CH}_2)_3\text{NH}_2)_2(\text{CO}_3)]\text{Cl} \cdot \text{H}_2\text{O}$, in red needles, by heating an aq. soln. of the corresponding dichloro-chloride with the calculated proportion of sodium carbonate in aq. soln., and subsequent precipitation with alcohol. Conc. hydrochloric acid, or an alcoholic soln. of hydrogen chloride restores the original dichloro-chloride. If trans-dichloroethylenediaminediamminochloride be heated with a soln. of potassium carbonate, **cobalt carbonatoethylenediaminediamminochloride**, $[\text{Co}(\text{NH}_3)_2\text{en}(\text{CO}_3)]\text{Cl}$, is formed in garnet-red crystals, easily soluble in hot water.

G. Vortmann reported **cobaltic tricarbonatohexammine**, $[\{\text{Co}(\text{NH}_3)_3\}_2(\text{CO}_3)_3] \cdot 3\text{H}_2\text{O}$, to be formed as a by-product in the preparation of the carbonatotetrammino-carbonate, in the most soluble part. Alcohol precipitates a violet-red oil, which can be dissolved in water; and the soln., on evaporation in air, furnishes the crystalline salt.

O. F. Wiede and K. A. Hofmann prepared **cobaltic sulphodithiocarbonatohexammine**, $[\{\text{Co}(\text{NH}_3)_3\}_2(\text{CS}_3)_2]\text{S}$, by passing nitric oxide through a mixture of freshly-prepared cobaltous hydroxide, aq. ammonia and carbon disulphide. The salt, which is mixed with an amorphous by-product, is purified by washing with alcohol. It crystallizes in black, lustrous rhombohedra, dissolves sparingly in water, yielding a yellowish-green soln., and is soluble in sodium hydroxide, with a

dark green coloration, at first without evolution of ammonia. It is decomposed by strong acids, with precipitation of sulphur, and, when heated, gives off carbon disulphide. By prolonged heating with sodium hydroxide, all the nitrogen is given off as ammonia. It can also be prepared by warming a mixture of cobalt hydroxide, ammonia, and carbon disulphide. K. A. Hofmann found that the ammonia molecules of the salt $\text{C}_2\text{S}_7\text{Co}_2(\text{NH}_3)_6$, are only removed with difficulty by acids. Fuming hydrochloric acid, at the ordinary temp., yields $\text{Co}_2\text{C}_2\text{ClS}_{14}\text{O}_{10}\text{H}_{26}$ as a black, crystalline precipitate, and a blue soln. is left. Acetic acid (60 per cent.), after many days at the ordinary temp., yields $(\text{CS}_3)_3\text{Co}_2\text{S}(\text{NH}_3)_2 \cdot \text{C}_2\text{H}_4\text{O}_2 \cdot 4\text{H}_2\text{O}$, whereby hydrogen sulphide is liberated and much cobalt dissolved. This salt crystallizes in small, lustrous black scales. Acetic anhydride acts very slowly, and after 4 days, yields $\text{C}_2\text{S}_3\text{Co}_2 \cdot 5\text{NH}_3$, as a black, lustrous, crystalline powder. The above results show that no ammonia is combined between the cobalt and sulphur, for, if this were the case, groups of the constitution $\text{CoNH}_3 \cdot \text{S} \cdot \text{NH}_3\text{Co}$, or $\text{Co} \cdot \text{NH}_3 \cdot \text{S} \cdot \text{Co}$, would be formed, and the compound $\text{C}_2\text{S}_7\text{Co}_2(\text{NH}_3)_6$ should give the reactions of hydrogen sulphide or thiocarbonic acid. S. M. Jørgensen discussed this subject. K. A. Hofmann also prepared **cobaltic disulphodithiocarbonatoaquopentammine**, $\text{Co}_2(\text{NH}_3)_5(\text{H}_2\text{O})(\text{CS}_3)_2\text{S}_2$, by the action of diazobenzene nitrate on the triammine salt, at 0° , after 24 hrs. It forms black, prismatic crystals, is slightly soluble in water, and gives an intense green coloration with a dil. soln. of sodium hydroxide. With a large mass of diazobenzene nitrate and more prolonged action, more ammonia is eliminated. K. A. Hofmann prepared **cobaltic hydrosulphatothiocarbonatotriammine**, $[\text{Co}(\text{NH}_3)_3(\text{CS}_3)(\text{HS})]$, by allowing diazobenzene nitrate to act on the hexammine, at ordinary temp., for 4 to 5 days, when black prisms resembling hornblende are formed, from which the hexammine can be reproduced by eliminating the HS-group. The salt dissolves in water, with an intense yellow coloration; and in a soln. of sodium hydroxide or aq. ammonia, to a greenish-yellow soln.; neither of these solns. gives a coloration with sodium nitroferrocyanide, or a deposit of silver sulphide on a piece of metallic silver. It therefore does not contain ammonia between the cobalt and sulphur.

C. Duval prepared a red **sodium cobaltic percarbonate**, $\text{Na}(\text{CoCO}_4)$, by treating a sat. soln. of 5 grms. of hexahydrated cobaltous chloride, and 8 grms. of sodium hydrocarbonate, with ozone.

§ 27. Cobaltous Nitrates

Anhydrous **cobaltous nitrate**, $\text{Co}(\text{NO}_3)_2$, was prepared by A. Guntz and F. Martin¹ by the action of nitric anhydride, or of a soln. of nitric anhydride in nitric acid, on hydrated cobaltous nitrate; and they also obtained it by the action of finely-divided cobalt on a soln. of silver nitrate in liquid ammonia: $\text{Co} + 2\text{AgNO}_3 = 2\text{Ag} + \text{Co}(\text{NO}_3)_2$. H. Lescœur, and R. Funk could not prepare the anhydrous salt by dehydrating the hydrate, since decomposition simultaneously occurs. According to F. A. C. Gren, W. A. Lampadius, J. L. Proust, H. Lescœur, B. Franz, G. C. Clark and H. K. Buckner, and N. A. E. Millon, a soln. of cobalt nitrate can be obtained by dissolving the metal, or the oxide, hydroxide or carbonate in dil. nitric acid; and when the carmine-red soln. is evaporated, it furnishes red, deliquescent crystals of the **hexahydrate**, $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$. J. C. G. de Marignac recommended evaporating the aq. soln. in vacuo, or cooling a conc. soln. V. M. Peshkova described the preparation of the salt. R. Funk, and F. Mylius and R. Funk studied the percentage solubility, *S*, of the salt in water, and found that:

	-18°	-22°	-29°	-23.5°	-22°	-10°	18°	55°	70°	91°
<i>S</i>	32.8	36.4	38.7	40.4	41.5	43.7	49.7	61.7	65.2	77.2
	Ice		$\text{Co}(\text{NO}_3)_2 \cdot 9\text{H}_2\text{O}$			$\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$		$\text{Co}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$		

The trihydrate melts at 91°. There is a metastable system at 56° when *S*=62.9, and the solid phase is the hexahydrate. The results are plotted in Fig. 142. A. Gorbow suggested that a **tetradecahydrate**, $\text{Co}(\text{NO}_3)_2 \cdot 14\text{H}_2\text{O}$, may exist, but there are no facts to support the inference. The region of stability of the **enneahydrate**, $\text{Co}(\text{NO}_3)_2 \cdot 9\text{H}_2\text{O}$, is indicated in the diagram; as it melts, it passes into the hexa-

hydrate. E. Frémy said that the crystals from a nitric acid soln. of the salt, dried in vacuo, are the *pentahydrate*, but this hydrate does not appear as a solid phase in the system: $\text{Co}(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$; R. Funk found that the hexahydrate acquires the composition of the *tetrahydrate*, by the loss of 2 mols. of water, when it is confined

FIG. 142.—The Solubility of Cobalt Nitrate in Water.

over sulphuric acid for 8 days, but there is no evidence of the formation of this hydrate as a solid phase in the system: $\text{Co}(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$. The region of stability of the *trihydrate*, $\text{Co}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$, is also indicated in Fig. 142, and R. Funk obtained it by evaporating the molten hexahydrate between 70° and 74° . H. Lescœur obtained the trihydrate by adding an excess conc. nitric acid to a soln. of the hexahydrate. R. Funk said that decomposition occurs when the attempt is made to dehydrate the trihydrate, but J. G. Viana and E. Moles said that the *dihydrate* is formed, without decomposition, between 60° and 70° . G. L. Clark and H. K. Buckner obtained what they regarded as a dihydrate, by keeping the hexahydrate for 3 months over conc. sulphuric acid; and also by warming the molten hexahydrate between 70° and 74° . J. G. Viana and E. Moles said that when the hexahydrate is re-crystallized from fuming nitric acid it consists of a mixture of the dihydrate and trihydrate.

A. Guntz and F. Martin observed that the anhydrous nitrate is a pale pink powder; R. Funk said that the trihydrate appears in rhombic plates; and the hexahydrate, according to A. Ditte, is rose-red which becomes blue and then green as it loses water while in the molten state. K. Schaum and H. Wüstenfeld said that the hexahydrate is colourless at the temp. of liquid air. The hexahydrate was found by J. C. G. de Marignac to yield red, monoclinic crystals with the axial ratios $a : b : c = 0.5875 : 1 : 0.9920$, and $\beta = 101^\circ 51'$. The crystals were also described by C. F. Rammelsberg. A. V. Rakowsky and V. M. Peshkova studied the isomorphism of the magnesium and cobalt hexahydrates, and M. Hasselblatt, with nickel nitrate. H. Traube observed that the hexahydrate forms two series of solid soln. with zinc bromate, one of which is cubic, and the other monoclinic. J. W. Retgers observed no solid soln. is formed with ammonium nitrate. S. Jakubsohn and M. Rabinowitsch observed that when the hexahydrate is warmed in a glass vessel at 21° to 22° , the glass is usually broken by the dilation of the salt. C. H. D. Bödeker gave 1.83 for the **specific gravity** of the hexahydrate at 14° . B. Gossner gave 1.888; G. L. Clark and H. K. Buckner, 1.880 to 1.883; and J. G. Viana and E. Moles, 1.872 at $25^\circ/4^\circ$. G. L. Clark and H. K. Buckner gave 2.397 for the sp. gr. of the dihydrate. E. N. Gapon, and P. F. Gaehr studied the relation between the sp. gr. and the concentration of soln.; G. L. Clark and H. K. Buckner gave for the mol. vol. of the anhydrous salt, 73.5. The sp. gr. of aq. soln. of the salt was measured by A. Heydweiller, I. Traube, F. Dreyer, F. Fouqué, H. C. Jones and co-workers, B. Franz, and R. Funk. The *International Critical Tables* gave the following summary for soln. with C per cent. of anhydrous salt:

C	1	2	6	10	16	20	25	30 per cent.
Sp. gr. { 18° .	1.0068	1.0317	1.0488	1.0848	1.1427	1.1841	1.2396	1.2998
{ 20° .	1.0064	1.0145	1.0485	1.0840	1.1420	1.1840	1.2390	1.2990
{ 25° .	1.0054	1.0135	1.0475	—	—	—	—	—

J. Wagner found for N -, $0.5N$ -, $0.25N$ -, and $0.125N$ -soln., respectively, 1.0728, 1.0369, 1.0184, and 1.0094. B. Cabrera and co-workers gave for the effect of temp. on the sp. gr. of a soln. with 0.2435 gram. $\text{Co}(\text{NO}_3)_2$ per litre, $1.2515\{1 - 0.0043(\theta - 20)\}$; for one with 0.3679 gram. per litre, $1.4254\{1 - 0.00047(\theta - 20)\}$; and for one with 0.4623 gram. per litre, $1.5783\{1 - 0.00048(\theta - 20)\}$. F. Dreyer observed that the

temp. of **maximum density** of soln. with 0.377, 0.767, 1.528, and 1.847 grms. per litre are, respectively, 3.40°, 2.79°, 1.64°, and 1.13°, when the value for water alone is 3.96°.

M. Torre studied the rate of **diffusion** of cobalt nitrate in aq. soln., and found that with soln. containing C grm. $\text{Co}(\text{NO}_3)_2$ per 100 c.c., the rates of diffusion, R , represented by the difference in the amount of salt in 100 c.c at the beginning and end of 24 hrs., are :

	$C=0.915$			$C=0.366$			$C=0.185$		
	30°	40°	50°	30°	40°	50°	30°	40°	50°
R	0.229	0.353	0.475	0.094	0.147	0.188	0.053	0.070	0.098

G. Tammann studied the **inner pressure** of soln. Z. H. Skraup and co-workers measured the **capillary rise** of the soln. in bibulous paper. J. Wagner found the **viscosity**, of N -, 0.5 N -, 0.25 N -, 0.125 N -soln. to be, respectively, 1.1657, 1.0754, 1.0318, and 1.0180 (water unity) at 25°. R. H. Adie found that for soln. with 0.05 and 0.025 mol $\text{Co}(\text{NO}_3)_2$ per litre, the **osmotic pressures** are, respectively, 2.14 and 1.35 atm.; and the factor i , 1.35 and 2.42.

H. Lescœur said that the hexahydrate is fairly stable over sulphuric acid, although in moist air the crystals are very deliquescent; E. Frémy, however, said that the hexahydrate effloresces over conc. sulphuric acid, losing a mol. of water; R. Funk observed that 2 mols. of water are lost in 8 days, and that there is nothing to show that the product is a veritable *tetrahydrate*. H. Lescœur found that in the **thermal decomposition** of the hexahydrate water is given off when the hexahydrate is heated to 20°, and at 60° the vap. press. remains constant until 3 mols. have been withdrawn; after that, the vap. press. curve drops considerably. N. A. E. Millon observed that the crystals of the hexahydrate fuse below 100°, forming a violet-red liquid which gives off water, it then forms a green, viscid liquid which intumesces, with the evolution of nitrous fumes, to form black cobaltic oxide. W. A. Tilden reported that the **melting-point** of the hexahydrate is 38°, but this datum is too low; J. M. Ordway gave 56°, and this is in agreement with R. Funks' 55°; J. G. Viana and E. Moles gave 55.5° for the m.p. of the hexahydrate. The molten salt at this temp. is a supersaturated soln., and some trihydrate is formed as solid phase, which, at a higher temp., passes into soln. R. Funk added that the trihydrate melts at 91°, and any attempt to dehydrate this product by raising the temp. results in a simultaneous decomposition of the nitrate. A. Ditte, G. C. Winkelblech, and H. Lescœur noted the decomposition of the nitrate when the attempt is made to dehydrate the hexahydrate. R. Funk could not get beyond the trihydrate without decomposition; and G. L. Clark and H. K. Buckner, and J. G. Viana and E. Moles got as far as the dihydrate, and said that the dihydrate is fairly stable between 70° and 100°. A. Guntz and F. Martin found that the anhydrous nitrate begins to decompose between 100° and 105°, forming cobaltous oxide.

F. Fouqué measured the **thermal expansion**, or the change in vol., δv , suffered by a soln. of C grms. of $\text{Co}(\text{NO}_3)_2$ per 1000 grms. of water, as the temp. rises from 0° to θ :

	$C=20$			$C=29.2$			$C=46.1$		
	12.1°	70°	92.5°	12.1°	70°	98.5°	11°	69.5°	99°
δv	0.00003	0.00029	0.00039	0.00008	0.00032	0.00040	0.00007	0.00034	0.00042

K. Jauch, and N. de Kolossowsky examined the **specific heat** of aq. soln. E. H. Riesenfeld and C. Milchsack gave 0.3733 cal. for the sp. ht. of the solid hexahydrate, and 0.5007 for the molten hexahydrate. H. Lescœur found that the **vapour pressure** of the hexahydrate is 100 mm. at 20°, and 58 mm. at 60°; that of the trihydrate is 30 mm. at 60°; and that of a saturated soln. of cobalt nitrate is about 9.3 mm. at 20°—*vide supra*. G. Tammann observed that the lowerings of the vap. press. of water at 100° by the dissolution of 15.38, 52.61, and 121.42

grms. of an anhydrous salt in 100 grms. of water are, respectively, 31.3, 144.3, and 358.4 mm. H. C. Jones and co-workers found the lowerings of the **freezing-point** of water, $\delta\theta$, by the dissolution of $[\text{Co}(\text{NO}_3)_2]$ grms. of the anhydrous salt in 100 grms. of water to be :

$[\text{Co}(\text{NO}_3)_2]$.	1.367	2.737	5.470	24.63	47.03
$\delta\theta$.	0.352°	0.658°	1.388°	8.418°	26.500°

E. H. Riesenfeld and C. Milchsack calculated the latent **heat of fusion** to be 30.2 cal. J. Thomsen gave for the **heat of formation** $(\text{Co}, \frac{1}{2}\text{O}_2, 2\text{HNO}_3\text{Aq.}) = 84.54$ Cals. ; $(\text{Co}, \text{N}_2, 3\text{O}_2, 6\text{H}_2\text{O}) = 219.32$ Cals. ; and $(\text{Co}, \text{O}_2, \text{N}_2\text{O}_4, 6\text{H}_2\text{O}) = 121.97$ to 123.33 Cals. ; whilst A. Guntz and F. Martin gave $\{\text{Co}(\text{NO}_3)_2, 6\text{H}_2\text{O}_{\text{solid}}\} = 8.20$ Cals. ; and $\{\text{Co}(\text{NO}_3)_2, 6\text{H}_2\text{O}_{\text{liquid}}\} = 16.84$ Cals. J. Thomsen gave for the **heat of neutralization**, $(\frac{1}{2}\text{Co}(\text{OH})_2, \text{HNO}_3) = 10.546$ Cals. ; and for the **heat of solution** of a mol of the hexahydrate in 400 mols of water, -4.96 Cals. A. Guntz and F. Martin gave for the heat of soln. of a mol of the anhydrous salt in 280 mols of water, 11.88 Cals. at 18°.

A. H. Pfund observed a maximum in the **reflected light** from the hexahydrate at 7.45μ . A. Bolland gave 1.52 for the **index of refraction** of the hexahydrate taken perpendicular to the direction of the edges of the prism. H. C. Jones and F. H. Getman gave for soln. with C mol of $\text{Co}(\text{NO}_3)_2$ per litre, with the D -line :

C .	0.0747	0.1495	0.2989	0.4484	0.7473	1.0462	1.4948
μ .	1.32700	1.32989	1.33395	1.33837	1.34606	1.35285	1.36347

and for soln. with 0.098 gm. $\text{Co}(\text{NO}_3)_2$ per c.c., sp. gr. 1.078, with light of wavelength $\lambda\mu$, R. W. Roberts gave :

λ .	589.3	420.0	400	380	360	350
μ .	1.3572	1.3620	1.3639	1.3663	1.3692	1.3705

Observations on the subject were also made by F. Fouqué, A. Hauke, A. Heydweiller, L. R. Ingersoll, and G. Limann. A. Hauke gave for the refraction of soln. with 3.12 and 1.41 per cent. of $\text{Co}(\text{NO}_3)_2$, with the C -line, and the μ^2 -formula, respectively (18.19) and 23.37. A. Heydweiller gave 23.07 for the D -line. A. Heydweiller also measured the dispersion. The **magnetic rotation** of the plane of polarized light, ω , is negative, and R. W. Roberts gave for soln. with 0.098 gm. $\text{Co}(\text{NO}_3)_2$ per c.c., sp. gr. 1.078, with a magnetic field of 13,510 gauss, at 20°, and light of wave-length $\lambda\mu$:

λ .	589.3	420.0	400	380	360	350
ω .	0.0128	0.0242	0.0278	0.0317	0.0364	0.0394

M. Schérer and R. Cordonnier, P. K. Pillai, F. Allison and E. J. Murphy, E. Miescher, R. Wachsmuth, L. R. Ingersoll, and O. Schönrock also discussed the subject. M. Trautz observed no **crystalloluminescence** or **triboluminescence** of the hexahydrate.

M. Kimura and M. Takewaki made observations on the ultra-violet **absorption spectrum** of the hexahydrate. H. M. Vernon, J. H. Gladstone, and P. Vaillant discussed the effect of dilution and of the raising of the temp. on the colour of soln. of the nitrate—*vide supra*, the colour of cobalt chloride ; and the absorption spectrum of soln. of the nitrate was examined by F. L. Cooper, W. N. Hartley, R. Hill and O. R. Howell, R. A. Houstoun, H. C. Jones and co-workers, T. R. Merton, K. Schäfer, and P. Vaillant.

S. Jakobsohn and M. Rabinowitsch found the sp. **electrical conductivity**, K mhos, of the hexahydrate is :

	-10°	-1°	15°	23°	37°	42°	45.5°	46.5°
$K \times 10^5$.	3.36	3.90	6.38	10.6	19.4	37.1	47.1	51.2

or $\log K = -0.40052 + 0.014135\theta$; and for the molten salt :

	61.5°	67.0°	72.0°	77.0°	83.0°	87.0°
$K \times 10^2$.	2.43	2.86	3.30	3.70	4.28	4.69

and they calculated that at 31°, the degree of loosening of the lattice is 0.0139.

The electrical conductivity of aq. soln. was measured by A. Heydweiller. E. Franke gave for the conductivity of a gram-equivalent of the salt in v litres at 25° :

v	32	64	128	256	512	1024
λ	93.63	98.56	102.2	105.8	108.7	111.2

H. C. Jones and J. N. Pearce found for the conductivity, μ , of soln. with a mol of cobalt nitrate in v litres, and the calculated percentage **ionization**, α :

v	100	40	20	10	2	1	0.5
μ	108.66	100.69	96.12	89.94	72.94	58.89	37.10
α	92.40	85.62	81.73	76.48	62.02	50.08	31.55

Observations were also made by W. H. Banks and co-workers, B. G. Whitmore, P. Vaillant, A. Heydweiller, H. C. Jones and F. H. Getman, H. C. Jones and A. P. West, and H. C. Jones and H. P. Bassett. L. Bruner found that the **hydrolysis** in aq. soln. of the nitrate is too small for measurement. C. Kullgren calculated for the degree of hydrolysis of soln. with an aq. of the salt in 8 and 32 litres, the respective values 0.00328 and 0.0152 per cent. at 85.5° , and 0.0048 and (0.0154) at 100° . H. C. Jones and co-workers calculated the **solvation** expressed as the number of mols. of water in combination with a mol. of the salt, if a litre of the soln., at that concentration, contained 1000 grms. of water. For soln. with C mols per litre:

C	0.0747	0.2989	0.7473	1.3451	2.0000	2.5700
Solvation	11.0	14.6	18.6	18.3	18.6	15.4

S. Labendzinsky measured the potential with soln. of cobalt nitrate—*vide supra*. L. F. Audrieth and L. F. Yntema studied the electrodeposition of cobalt from soln. of the nitrate in liquid ammonia; H. Brandes, the polarization of platinum in soln. of the nitrate; and A. Klemenc and H. F. Hohn, the glow electrolysis.

G. Jäger and S. Meyer found the **magnetic susceptibility** of soln. of cobalt nitrate to be 56.8×10^{-6} mass unit; and O. Liebknecht and A. P. Wills gave 57.4×10^{-6} mass unit. Observations were also made by G. Wiedemann, P. Plessner, A. Cabrera and co-workers, A. Heydweiller, P. Weiss and co-workers, H. Mosler, L. A. Welo, A. Trümpler, and P. Philipp. A. Quartaroli said that conc. soln. are paramagnetic; but with dil. soln., the diamagnetism of the water masks the paramagnetism of the salt. The neutral point occurs with soln. having 3.78 grms. of cobalt per litre. H. Stüdemann said that the susceptibility of the solid hexahydrate does not change when it is dissolved in water. A. Chatillon gave for the susceptibility of the soln., $\chi_{\text{soln.}}$ mass unit, and of the dissolved $\text{Co}(\text{NO}_3)_2$, χ mass unit at different temp.:

	11°	19°	49°	81°	105.5°	128°
$\chi_{\text{soln.}} \times 10^6$	4.952	4.812	4.463	3.890	3.598	3.357
$\chi \times 10^6$	59.56	58.08	54.36	48.28	45.18	42.66

The effect of temp. was also measured by G. Wiedemann, G. Jäger and S. Meyer, and P. Plessner. B. Cabrera and co-workers gave for the sp. mol. susceptibility of soln., $\chi_{\text{mol.}}$ mass unit, with C grm. of $\text{Co}(\text{NO}_3)_2$ per gram of soln., at about 25° :

C	0.4623	0.05526	0.01737	0.00944	0.008056	0.005076
$\chi_{\text{mol.}} \times 10^6$	10,060	10,273	10,399	10,244	10,203	10,076

they also gave for the sp. susceptibility $\chi_{\text{soln.}}$ mass unit, of the soln., with C per cent. $\text{Co}(\text{NO}_3)_2$, and of the $\text{Co}(\text{NO}_3)_2$ mol., $\chi_{\text{mol.}}$ mass unit, at about 25° , in the presence of nitric acid—mol. HNO_3 per mol. $(\text{Co}(\text{NO}_3)_2)$:

C	0.8056	0.8058	0.8062	0.8066	0.8075	0.8093
HNO_3	1.836	6.80	19.5	30.0	55.4	106.1
$\chi_{\text{soln.}} \times 10^6$	-0.5743	-0.5540	-0.5244	-0.4959	-0.4350	-0.3042
$\chi_{\text{mol.}} \times 10^6$	10,131	10,186	10,156	10,160	10,080	9990

Observations on the effect of concentration were made by P. Vaillant, P. Philipp, A. Heydweiller, and G. Falckenberg and R. Oppermann.

J. H. Weibel studied the action of **hydrogen**. J. L. Proust discussed the use of a soln. of cobaltous nitrate as a sympathetic ink (*q.v.*). V. N. Ipatéeff and B. Muromtzeff found that **hydrogen** at 200° to 300°, and 250 atm. press., precipitates cobaltic oxide from soln. of cobaltous nitrate; and S. Miyamoto, that the salt is reduced by hydrogen in the silent discharge. A. Mailfert studied the action of **ozone**. The hydrolysis and solubility of the salt in **water** have been already discussed. G. C. Winkelblech, and C. D. Braun found that the blue precipitate is obtained by adding an excess of ammonia to a well-boiled, aq. soln. of the nitrate. If air be not excluded, the precipitate turns grass-green, and gradually re-dissolves in the liquid, but a portion remains undissolved, and if this be washed with boiled water with the exclusion of air, and dried, it forms a grass-green powder which was considered to be **cobaltous decahydroxydinitrate**, $\text{Co}(\text{NO}_3)_2 \cdot 5\text{Co}(\text{OH})_2$. J. Habermann reported **cobaltous hexahydroxydinitrate**, $\text{Co}(\text{NO}_3)_2 \cdot 3\text{Co}(\text{OH})_2 \cdot 3\text{H}_2\text{O}$, by dropping a very dil. soln. of ammonia into a well-stirred, boiling, conc. soln. of cobaltous nitrate. The colour is green on the outside, and blue in the interior. A. Bernadi observed the formation of a green precipitate with sodium hydroxide, as indicated in connection with the chloride (*q.v.*). W. Feitknecht said that the lattice corresponds with alternate layers of the normal salt and of the hydroxide. L. Archbutt, and H. Grossmann observed that a little cobalt nitrate favoured the decomposition of a soln. of **sodium dioxide**. D. Vitali found that **silver oxide** precipitates the hydroxide from aq. soln. of the nitrate.

K. Fredenhagen observed that cobalt nitrate is insoluble in liquid **hydrogen fluoride**. According to V. Cuvelier, a mixed soln. of cobaltous nitrate, $\text{Co}(\text{NO}_3)_2 \cdot 5\text{H}_2\text{O}$, and chloride, $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$, furnishes solid phases when it contains 40.68 per cent. of the nitrate, and 12.01 per cent. of the chloride. F. P. Venable observed that a conc. soln. of cobaltous nitrate mixed with **hydrochloric acid** is coloured green by ferric oxide. A. Schoep noted the occurrence in Katanga, Congo, of a hydrated **cobaltous chloronitrate**, in blue needles, presumably isomorphous with buttgenbachite, $18\text{CuO} \cdot 0.3\text{Cl} \cdot \text{N}_2\text{O}_5 \cdot 19\text{H}_2\text{O}$. The mineral was called **julienite**—after H. Julien. The refractive index of the tetragonal crystals is 1.556; and the sp. gr. is 1.594 at 20°. The crystals are soluble in water.

J. Thomsen found that the thermal value of the reaction of aq. soln. of cobaltous nitrate and **hydrogen sulphide**, is 3.68 Cals. E. Schürmann observed that a soln. of cobaltous nitrate is completely decomposed by **ferrous and manganous sulphides**, partially decomposed by **nickel sulphide**, and a little decomposed by **zinc sulphide**. C. Dufraisse and D. Nakae studied the catalytic action on the oxidation of soln. of **sodium sulphite**,

According to A. Ditte and F. Friedrichs, cobaltous nitrate is very sparingly soluble in **nitric acid**. A. Guntz and F. Martin noted that the anhydrous nitrate is soluble in liquid **ammonia**; H. Hunt and L. Boneyk said that the salt is insoluble in liquid ammonia at 25°; and E. G. Franklin and C. A. Kraus, that the hexahydrate forms a yellow soln. with liquid ammonia. The subject was studied by F. Friedrichs, and G. Yersin. H. Petzler studied the system: $\text{Co}(\text{NO}_3)_2 \cdot \text{NH}_3 \cdot \text{H}_2\text{O}$, at 25°. According to A. Guntz and F. Martin, if finely-divided cobalt reacts with silver nitrate dissolved in liquid ammonia, and the clear soln. evaporated, orange-red spangles of **cobaltous enneamminonitrate**, $(\text{Co}(\text{NO}_3)_2 \cdot 9\text{NH}_3)$, are formed. The salt explodes if heated rapidly, but if heated slowly, and exposed under reduced press., ammonia is given off, but before all the ammonia is expelled, nitrous fumes are evolved. The salt is decomposed by water, with the precipitation of cobaltous hydroxide. According to F. Ephraim and E. Rosenberg, G. L. Clark and H. K. Buckner, and G. L. Clark, **cobaltous hexamminonitrate**, $\text{Co}(\text{NO}_3)_2 \cdot 6\text{NH}_3$, is formed in rose-red, or reddish-brown crystals when trihydrated cobaltous nitrate is treated with dry ammonia. G. L. Clark and H. K. Buckner found the sp. gr. to be 1.473; E. Birk and W. Biltz gave 1.476 at 25°/4°; and W. Biltz found the

mol. vol. of the contained NH_3 -groups is 22. F. Ephraim and E. Rosenberg gave for the dissociation press., p mm.:

	21°	109.5°	131°	137.5°	152°	153°	157.5°	160°
p	13	129	209	271	471	535	650	(760)

L. J. Thénard, and E. Frémy reported a *dihydrate*, $\text{Co}(\text{NO}_3)_2 \cdot 6\text{NH}_3 \cdot 2\text{H}_2\text{O}$, to be formed when a conc., aq. soln. of cobaltous nitrate is treated with ammonia while air is excluded. The basic nitrate first precipitated dissolves in an excess of ammonia, forming a wine-red soln. which deposits rose-red crystals. These can be rapidly washed with aq. ammonia, pressed between bibulous paper, and dried in vacuo. The crystals were said to be stable in air, and to be decomposed by water, with the precipitation of a green basic salt. There is some doubt about the water of hydration. H. Hess found that the salt is soluble in ammonia.

H. Franzen and O. von Mayer obtained **cobaltous trihydrazinenitrate**, $\text{Co}(\text{NO}_3)_2 \cdot 3\text{N}_2\text{H}_4$, by heating a mixture of 10 grms. of cobaltous hexamminonitrate with 30 c.c. of 50 per cent. **hydrazine hydrate**, on a water-bath for 1 hr., washing the product with alcohol, and ether, and drying it in vacuo over conc. sulphuric acid and potassium hydroxide. The pale yellow powder explodes when heated, or when treated with conc. sulphuric acid. It is decomposed by hot water to form a green substance. S. Kitashima studied the oxidation of the soln. of cobaltous nitrate by **sodium bismuthate**.

J. H. Weibel studied the action of **carbon monoxide**. C. F. Wenzel observed that the hexahydrate is soluble in **ethyl alcohol**—the percentage solubility is about 7.4. P. Vaillant, F. L. Cooper, and R. A. Houstoun and co-workers discussed the absorption spectrum of the red soln. which is formed. H. A. Curtis and R. M. Burns obtained a wine-red soln. of the hexahydrate in **iso-amyl alcohol**—the soln. of the chloride is blue—the addition of hydrochloric acid turns the soln. blue; hydrogen sulphide precipitates nearly all the cobalt as sulphide—with the chloride only a small proportion is so precipitated; aq. ammonia gives a dirty green precipitate; and calcium bromide colours the soln. blue. F. W. O. de Coninck noted the solubility of the hexahydrate in **ethylene glycol**—100 grms. of a sat. soln. contain 80 grms. of $\text{Co}(\text{NO}_3)_2$. A. Grün and E. Boedecker obtained a complex salt with ethylene glycol, namely, $\text{Co}(\text{NO}_3)_2 \cdot 3\text{C}_2\text{H}_4(\text{OH})_2$; with **propylene glycol**, a complex $\text{Co}(\text{NO}_3)_2 \cdot 3\text{C}_3\text{H}_7(\text{OH})_2$; and with **pinacone**, the complex $\text{Co}(\text{NO}_3)_2 \cdot 3\text{C}_6\text{H}_{12}(\text{OH})_2 \cdot 2\text{H}_2\text{O}$. A. Naumann, and K. P. McElroy and W. H. Krug, noticed that it is readily soluble in **acetone**. The absorption spectrum of the red soln. was studied by R. A. Houstoun and co-workers; the electrical conductivity, by F. Bauer; and the magnetic susceptibility, by A. Quartaroli. A. Naumann observed that it is soluble in **methyl acetate**, and sparingly soluble in **ethyl acetate**. J. Schröder and H. Steiner said that 100 grms. of methyl acetate dissolve 16.4 grms. of $\text{Co}(\text{NO}_3)_2$; and the raising of the b.p. of the red soln. shows that much ionization occurs. M. Stuckgold found the mol. conductivities of soln. of a mol. of the nitrate in 14.02, 32.81, and 91.54 litres of **urethane**, at 60°, are, respectively, 2.23, 2.36, and 2.80. T. Murayasu found the electrical conductivity of 0.5N- $\text{Co}(\text{NO}_3)_2$ is reduced by **glycine**. According to G. A. Barbieri and F. Calzolari, L. Vanino and A. Schinner, R. Rea, and G. Rossi, cobalt nitrate forms a complex with **hexamethylenetetramine**; J. Reilly, and J. Reilly and W. J. Hickinbottom, one with *p*-**nitrosodim-butylaniline**; R. Cernatescu and co-workers, with **phenylenediamine**; J. Frejka and L. Zahlova, with **diaminobutane**; A. Naumann, G. Rossi, and F. Reitzenstein, one with **pyridine**; F. L. Hahn and co-workers, one with α -**acetaminopyridine**; E. Borsbach, and F. Reitzenstein, one with **quinoline**; A. Rosenheim and V. J. Meyer, one with **thiocarbamide**; J. Moitessier, one with **phenylhydrazine**; and J. V. Dubsky and F. Brychta, one with **dimethylglyoxime**. E. J. Fischer obtained a bluish-violet precipitate with **imidazole**, $(\text{C}_3\text{H}_4\text{N}_2)_3$; with **benzimidazole**, $\text{C}_7\text{H}_6\text{N}_2$, and with **3:5-dimethylpyrazole**; W. Hieber and E. Levy, with **mono-, di-, and trihydroxyethylamine**; and E. A. Jensen and E. R. Madsen, with

thiosemicarbazide. C. Dufraisse and D. Nakae studied the catalytic oxidation of **acraldehyde**, **benzaldehyde**, **furfuraldehyde**, **styrene**, and **turpentine**.

T. Heymann and K. Jellinek studied the equilibrium of **nickel** in the soln, $\text{Ni} + \text{Co}^{++} \rightleftharpoons \text{Co} + \text{Ni}^{++}$. V. Cuvelier studied the ternary system **cobalt chloride**, cobalt nitrate, and water, at 20° ; no evidence of a complex was observed; and the only solid phases were $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$, and $\text{Co}(\text{NO}_3)_2 \cdot 5\text{H}_2\text{O}$.

K. W. Wilcox and C. R. Bailey studied the ternary system: $\text{Co}(\text{NO}_3)_2 - \text{Cu}(\text{NO}_3)_2 - \text{H}_2\text{O}$, Fig. 143, and observed the formation of small, smoke-blue,

FIG. 143.—The Ternary System: $\text{Cu}(\text{NO}_3)_2 - \text{Co}(\text{NO}_3)_2 - \text{H}_2\text{O}$, at 14° .

deliquescent crystals of **copper cobaltous nitrate**, $6\text{Cu}(\text{NO}_3)_2 \cdot \text{Co}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$, at 14° , not at 20° ; the crystals melt at 17° , and are decomposed by water. W. Schrenzlowski discussed the isodimorphous solid soln. formed by copper and cobaltous nitrates. A. Mailhe reported **copper cobaltous trihydroxynitrate**, $\text{Co}(\text{NO}_3)_2 \cdot 3\text{Cu}(\text{OH})_2$, or, according to A. Werner, $\text{Cu}_2(\text{OH})_4\text{Cu} = (\text{OH})_2\text{Co}(\text{NO}_3)_2$, to be formed by the action of a soln. of cobaltous nitrate on $4\text{CuO} \cdot \text{H}_2\text{O}$. The green, monoclinic plates are isomorphous with those of $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{CuO} \cdot 3\text{H}_2\text{O}$. The salt was discussed by W. A. Endriss. F. T. Frerichs and E. F. Smith reported a *didymium cobaltous nitrate*, $2\text{Di}(\text{NO}_3)_3 \cdot 3\text{Co}(\text{NO}_3)_2 \cdot$

$48\text{H}_2\text{O}$, to be formed in dark red, deliquescent, and very soluble crystals from a soln. of the component salts. G. Jantsch likewise prepared **lanthanum cobaltous nitrate**, $\text{Co}_3[\text{La}(\text{NO}_3)_6]_2 \cdot 24\text{H}_2\text{O}$, of sp. gr. 2.131 at $0^\circ/4^\circ$, m.p. 101.8° , and 100 c.c. of a sat. soln. in nitric acid of sp. gr. 1.325, contain 10.92 grms. of hydrated salt at 16° ; and **cerous cobaltous nitrate**, $\text{Co}_3[\text{Ce}(\text{NO}_3)_6]_2 \cdot 24\text{H}_2\text{O}$, of sp. gr. 2.157 at $0^\circ/4^\circ$, m.p. 98.5° , and 100 c.c. of a sat. soln. in nitric acid of sp. gr. 1.325, contain 10.33 grms. of hydrated salt at 16° ; M. Holzmann, and R. J. Meyer and R. Jacoby prepared **ceric cobaltous nitrate**, $\text{CoCe}(\text{NO}_3)_8 \cdot 8\text{H}_2\text{O}$, in dark reddish-violet crystals from a soln. of the component salts in nitric acid; and R. J. Meyer and R. Jacoby obtained **thorium cobaltous nitrate**, $\text{ThCo}(\text{NO}_3)_8 \cdot 8\text{H}_2\text{O}$, in a similar manner. G. Jantsch prepared **praseodymium cobaltous nitrate**, $\text{Co}_3[\text{Pr}(\text{NO}_3)_6]_2 \cdot 24\text{H}_2\text{O}$, in wine-red crystals of sp. gr. 2.176 at $0^\circ/4^\circ$, m.p. 97° , and 100 c.c. of a sat. soln. in nitric acid of sp. gr. 1.325, contain 12.99 grms. of hydrated salt at 16° ; **neodymium cobaltous nitrate**, $\text{Co}_3[\text{Nd}(\text{NO}_3)_6]_2 \cdot 24\text{H}_2\text{O}$, in wine-red crystals of sp. gr. 2.195 at $0^\circ/4^\circ$, m.p. 98.5° , and 100 c.c. of a sat. soln. in nitric acid of sp. gr. 1.325, contain 15.16 grms. of hydrated salt at 16° ; **samarium cobaltous nitrate**, $\text{Co}_3[\text{Sm}(\text{NO}_3)_6]_2 \cdot 24\text{H}_2\text{O}$, in brownish-red crystals of sp. gr. 2.237 at $0^\circ/4^\circ$, m.p. 83.2° , and 100 c.c. of a sat. soln. in nitric acid of sp. gr. 1.325, contain 34.27 grms. of hydrated salt at 16° ; and **gadolinium cobaltous nitrate**, $\text{Co}_3[\text{Gd}(\text{NO}_3)_6]_2 \cdot 24\text{H}_2\text{O}$, in pale red crystals of sp. gr. 2.315 at $0^\circ/4^\circ$, m.p. 63.2 , and 100 c.c. of a sat. soln. in nitric acid of sp. gr. 1.325, contain 45.14 grms. of hydrated salt at 16° . G. Urbain and H. Lacombe obtained red crystals of **bismuth cobaltous nitrate**, $3\text{Co}(\text{NO}_3)_2 \cdot 2\text{Bi}(\text{NO}_3)_3 \cdot 24\text{H}_2\text{O}$, of sp. gr. 2.48 at $16^\circ/16^\circ$, and m.p. 58° . G. Jantsch observed that 100 c.c. of a sat. soln. in nitric acid of sp. gr. 1.325, contain 54.67 grms. of the hydrated salt at 16° . A. V. Rakowsky and V. M. Peshkova found that at 14° to 17° , hexahydrated **manganese cobalt nitrates** form a continuous series of solid soln.

§ 28. Cobaltic Nitrate and its Complex Salts

G. C. Winkelblech¹ found that a soln. of cobaltous oxide in nitric acid forms some **cobaltic nitrate**, $\text{Co}(\text{NO}_3)_3$, but it is soon reduced to cobaltous nitrate by light and heat. H. Marshall obtained evidence of the formation of cobaltic nitrate in the electrolysis of a conc. soln. of cobaltous nitrate in a partitioned cell. The liquid became indigo-blue while the current was passing, but the original colour returned when the circuit was broken. The blue colour is supposed to be produced by the presence of unstable cobaltic nitrate. S. Kitashima oxidized a soln. of cobalt

nitrate in conc. nitric acid by sodium bismuthate, and observed that the blue filtrate contained cobaltic nitrate; if dil. nitric acid is employed, the soln. is red, but it shows the absorption spectrum of cobaltic nitrate. The degree of oxidation of a soln. with sodium bismuthate in the presence of a given proportion of nitric acid, attains a limit. The cobaltic nitrate soln. is gradually reduced when the soln. is kept for some time. The salt is known only in aq. soln., but a remarkable series of stable amino-salts have been prepared.

A. Rosenheim and I. Koppel observed that when nitrogen trioxide is passed into a slurry of cobalt carbonate, a brown soln. is formed which, on evaporation at room temp., furnishes black crystals of **cobaltosic oxynitritonitrate**, $2\text{CoO} \cdot \text{Co}_2\text{O}_3 \cdot 3\text{N}_2\text{O}_3 \cdot \text{Co}(\text{NO}_3)_2 \cdot 14\text{H}_2\text{O}$. It is not clear if the nitrate is an integral part of the compound, or simply an admixture. T. Suzuki also obtained analogous salts, $\text{Co}_3''\text{Co}_2'''(\text{NO}_2)_6(\text{NO}_3)_2(\text{OH})_4 \cdot 12\text{H}_2\text{O}$, and $\text{Co}_4''\text{Co}_2'''(\text{NO}_2)_8(\text{NO}_3)_2(\text{OH})_4 \cdot 15\text{H}_2\text{O}$.

The CoA₆ or Hexammine Family

E. Frémy² prepared **cobaltic hexamminonitrate**, $[\text{Co}(\text{NH}_3)_6](\text{NO}_3)_3$, by the oxidation of an ammoniacal soln. of cobaltous nitrate in air; L. Jacobsen, by oxidizing an ammoniacal soln. of cobaltous nitrate, mixed with ammonium nitrate, by silver nitrate; J. B. Rogojsky, by the action of silver nitrate on a soln. of the corresponding chloride acidified with hydrochloric acid; O. W. Gibbs and F. A. Genth, by adding barium chloride to a soln. of the sulphate; and F. Rose, and S. M. Jörgensen, by treating an aq. soln. of the chloride with nitric acid. S. M. Jörgensen, and L. Jacobsen used iodine as oxidizing agent, and H. and W. Biltz thus describe this process:

Dissolve 24 grms. of cobalt carbonate by warming it with just enough nitric acid for dissolution, and dilute the filtered liquid to make 100 c.c. Add 200 c.c. of conc., aq. ammonia, and to the boiling liquid add, slowly at first, 25.4 grms. of iodine. The reaction is vigorous, and a pale yellowish-brown precipitate is formed. Iodine should all have been added in half an hour. After the mixture has stood 2 hrs.' cooling, filter and wash the precipitate with ammoniacal water. Boil the precipitate with 200 c.c. of approximately 56 per cent. nitric acid. The iodine is liberated, and can be partially recovered by placing two funnels to form a double cone in the neck of the flask. When all the iodine has been expelled, the precipitate is filtered off; drained by suction; washed first with water containing nitric acid, then with alcohol; and dried in the water-oven. Yield about 22 grms.

The crystals are yellow, or orange-yellow plates or needles, which J. D. Dana said belong to the tetragonal system, and have the axial ratio $a : c = 1 : 1.016$. The crystals were examined by F. M. Jäger. E. von Fedoroff discussed the isomorphism of the salt with the corresponding $[\text{Ir}(\text{NH}_3)_6](\text{NO}_3)_3$. E. Birk and W. Biltz gave 1.804 for the sp. gr. at $25^\circ/4^\circ$, and 192.5 for the mol. vol. E. Birk and W. Biltz also discussed the mol. vol. of the NH_3 -groups. R. Robl observed no luminescence in ultra-violet light. A. Werner and A. Miolati found the mol. conductivity, μ , of a soln. of a mol. of the salt in v litres of water, at 25° , to be:

v	.	.	.	128	256	512	1024	2048
μ	.	.	.	329.7	355.1	380.8	397.0	413.4

P. Pascal gave -0.258×10^{-6} mass unit for the magnetic susceptibility; W. Biltz, L. C. Jackson, R. Ladenburg, and E. Rosenbohm also studied the magnetic properties of the salt.

According to S. M. Jörgensen, 100 grms. of water dissolve 1.67 grms. of the salt, at ordinary temp., and it is almost insoluble in dil. acids. P. Mosimann, and F. Ephraim and P. Mosimann found that a sat., aq. soln. at 18° contains 1.974 grms. or 0.033 mol per litre; and J. N. Brönsted and A. Petersen, at 0° , 0.0202 mol, and at 20° , 0.052 mol per litre. J. N. Brönsted studied the action of some salts on the solubility. A. Benrath and H. Pitzler, and H. Pitzler studied the equilibrium conditions in the system: $[\text{Co}(\text{NH}_3)_6](\text{NO}_3)_3 + 3\text{NH}_4\text{OH} \rightleftharpoons [\text{Co}(\text{NH}_3)_6](\text{OH})_3$.

+3NH₄NO₃. E. Böhm oxidized an ammoniacal soln. of cobaltous nitrate in hydrofluoric acid, and washed the product with dil. hydrofluoric acid. Honey-yellow, tetrahedral crystals of **cobaltic hexamminofluonitrate**, [Co(NH₃)₆](NO₃)₂F, remained. S. M. Jörgensen warmed an ammoniacal soln. of cobaltous nitrate with a soln. of iodine and potassium iodide, and obtained small, rectangular prisms, which may be **cobaltic hexamminoiodonitrate**, [Co(NH₃)₆](NO₃)₂I, but more probably a solid of the nitrate and iodide. S. M. Jörgensen treated an ammoniacal soln. of the hexamminonitrate with dil. sulphuric acid, or sodium sulphate, and obtained orange-yellow octahedra of **cobaltic hexamminosulphatonitrate**, [Co(NH₃)₆](SO₄)(NO₃). A. Benrath, and A. Benrath and H. Würzburger observed that the solubilities of the salt, expressed in grms. of Co in 100 grms. of water in the presence of the following proportions of nitric acid—grms. per 100 c.c. of water—at 30°, were:

HNO ₃	.	.	0.000	1.107	2.922	4.600	6.380
Co	.	.	0.450	0.225	0.082	0.0521	0.0338

The curve remains continuous and the solid phase becomes pale in colour when the soln. contains 16 per cent. of HNO₃. Below that concentration, the solid phase is [Co(NH₃)₆](NO₃)₃; and above that concentration, **cobaltic hexamminohydro-nitrate**, [Co(NH₃)₆](NO₃)₃.HNO₃, which furnishes orange-yellow needles. F. W. Bergstrom observed no definite product is formed by a soln. of potassium amide in liquid ammonia. S. M. Jörgensen found that cold, sat., aq. soln. give precipitates with dil. nitric acid, and conc. hydrochloric or hydrobromic acid, potassium iodide, chromate, dichromate, ferrocyanide, ferricyanide, cobalticyanide, or chromicyanide, with sodium pyrophosphate, ammonium oxalate, and hydrochloroauric acid. Dil. sulphuric acid gives the sulphatonitrate; a mixture of hydrochloro-platinic acid and sulphuric acid gives a sulphatoplatinic salt; sodium hydrophosphate with ammonia gives a precipitate; and mercuric chloride gives no precipitate, but in the presence of hydrochloric acid, a double chloride is precipitated. E. Wilke-Dörfurt and co-workers studied **cobaltic hexamminodinitratofluosulphonate**, [Co(NH₃)₂](NO₃)₂SO₃F.

A. Werner and E. Berl obtained **cobaltic hexahydroxylaminenitrate**, [Co(NH₂OH)₆](NO₃)₃, in golden-yellow crystals, by treating the corresponding chloride with nitric acid, free from the lower oxides of nitrogen, and the product re-precipitated 3 or 4 times from a soln. in water. During the operations, the product is liable to explode, with the development of gas and the reduction of cobaltic to the cobaltous salt. C. S. Borzekowsky prepared the dextro- and lævo-forms of **cobaltic hydroxylaminebisethylenediamineamminonitrate**, [Co(NH₃)(NH₂OH)_{en}]₂(NO₃)₃.

S. M. Jörgensen,³ and L. L. Lehrfeld prepared **cobaltic trisethylenediaminenitrate**, [Co en₃](NO₃)₃, by heating the hexamminonitrate, or the nitratopentamminonitrate, with an aq. soln. of monohydrated ethylenediamine; or by precipitation with alcohol from a soln. of the corresponding chloride in dil. nitric acid; and F. M. Jäger, by treating the corresponding bromide with a warm soln. of the theoretical proportion of silver nitrate, and evaporating for crystallization. The dark red, or brownish-red crystals were found by F. M. Jäger to be rhombic bipyramids with the axial ratios $a : b : c = 0.8079 : 1 : 1.1279$. The crystals were also studied by E. von Fedoroff. F. M. Jäger gave 1.694 for the sp. gr. at 17°, and 1.709 at 25°/4°; 250.94 for the mol. vol. at 17°; and for the topic axial ratios, $\chi : \psi : \omega = 5.2476 : 6.5513 : 7.2983$. J. Angerstein studied the absorption spectrum. A. Werner and C. Herty found the mol. conductivity, μ , of soln. with a mol. of the salt in *v* litres, at 25°,

<i>v</i>	.	.	125	250	500	1000	2000
μ	.	.	294.69	316.40	363.63	359.84	375.19

E. Rosenbohm gave -0.300×10^{-6} mass unit for the magnetic susceptibility, and L. C. Jackson studied the magnetic properties. S. M. Jörgensen observed that the salt is readily soluble in water; it is not precipitated from its aq. soln. by nitric acid; and when evaporated with hydrochloric acid, the nitrate passes into the chloride. A. Werner, and F. M. Jäger observed that by treating the active bromides with the theoretical pro-

portions of silver nitrate, the *dextro-salt* and the *laevo-salt* can be obtained in dark red crystals, which, according to F. M. Jäger, belong to the rhombic system, have the axial ratios $a : b : c = 0.8652 : 1 : 0.6009$ for the *dextro-salt*, and $0.8647 : 1 : 0.5983$ for the *laevo-salt*. No marked cleavage was observed. The sp. gr. of the *dextro-salt* is 1.725 at $25^\circ/4^\circ$, and of the *laevo-salt*, 1.729 at $25^\circ/4^\circ$. J. Angerstein studied the absorption spectrum. A. Werner found the sp. rotations of 1 per cent. soln. to be $[\alpha] = 132^\circ$ for the *dextro-salt*, and -130° for the *laevo-salt*. F. M. Jäger studied the mol. rotations of these salts. E. Rosenbohm found the magnetic susceptibility of the *dextro-salt* to be -0.341×10^{-6} mass unit, and of the *laevo-salt*, -0.340×10^{-6} mass unit. L. C. Jackson studied the magnetic properties of the salt.

P. Pfeiffer and T. Gassmann prepared soluble, yellow, acicular crystals of **cobaltic tripropylenediaminenitrate**, $[\text{Co}(\text{pn}_3)(\text{NO}_3)_3]$, by adding the theoretical proportion of silver nitrate to the corresponding chloride; and E. Rosenbohm found the magnetic susceptibility of the *laevo-salt* to be -0.385×10^{-6} mass unit. L. C. Jackson also studied the magnetic properties of the salt. F. M. Jäger and H. B. Blumendal obtained **cobaltic trans-trisyclopentanediaminenitrate**, $[\text{Co}(\text{C}_5\text{H}_{12}\text{N}_2)_3](\text{NO}_3)_3$, in red needles, by adding the theoretical proportion of silver nitrate to a soln. of the chloride. The *dextro-salt* and *laevo-salt* were obtained from the corresponding cyclopentanediamines. The *trihydrate* forms hexagonal crystals, and the *tetrahydrate* cubic crystals. The hydrates lose water on exposure to air. K. R. Lange, and A. Werner and C. Kreutzer prepared **cobaltic cis-bisethylenediaminediamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{en}_2](\text{NO}_3)_3$, along with the trans-salt, by the action of liquid ammonia on dinitratobisethylenediaminenitrate, and fractional crystallization from hot, neutral, aq. soln. The trans-salt is the less soluble form. If conc., aq. ammonia be used in place of liquid ammonia, or if the aq. soln. be not quite neutral, a syrupy liquid is produced instead of the dark reddish-yellow crystals. According to A. Werner and Y. Shibata, the optically active camphor bromosulphonates, or the active chlorides, in nitric acid soln., when treated with silver nitrate, yield the *dextro-salt* or the *laevo-salt* in golden-yellow crystals. The sp. rotations of 0.5 per cent. aq. soln. are $[\alpha] = 46^\circ$ for the *dextro-salt*, and -44° for the *laevo-salt*. R. von Arx, and J. Lifschitz studied the rotary dispersion. The corresponding **cobaltic trans-bisethylenediaminediamminonitrate** was obtained by A. Werner and co-workers, along with the trans-nitratobisethylenediamine amminonitrate, by the oxidation of trans-isothiocyanatobisethylenediamineamminothiocyanate with nitric acid—there is a smaller yield with the cis-compound; and by treating the corresponding chloride with nitric acid. The brown pyramids were found by F. M. Jäger to belong to the rhombic system, and to have the axial ratios $a : b : c = 0.9473 : 1 : 0.6708$. A. Werner and C. Herty found the mol. conductivity, μ , of a soln. of a mol of the salt in v litres of water, at 25° , to be :

v	125	250	500	1000	2000
μ	312.01	340.09	364.32	384.13	401.90

A. Werner and K. Dawe reported **cobaltic bispropylenediaminediamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{pn}_2](\text{NO}_3)_3$, to be formed, in thin, straw-yellow plates, where the corresponding chloride is evaporated twice with nitric acid (1:1). F. M. Jäger and H. B. Blumendal obtained **cobaltic trans-bisethylenediaminecyclopentanediaminenitrate**, $[\text{Co}\text{en}_2(\text{C}_5\text{H}_{12}\text{N}_2)](\text{NO}_3)_3$, in brownish-red needles, by treating the corresponding iodide with silver nitrate. F. M. Jäger reported **cobaltic bisethylenediaminephenanthrolinenitrate**, $[\text{Co}\text{en}_2(\text{C}_{12}\text{H}_8\text{N}_2)](\text{NO}_3)_3$, by treating the iodide with silver nitrate. The crystals are triclinic with the axial ratios $a : b : c = 0.9938 : 1 : 0.8574$. W. A. Redeker prepared **cobaltic pyridinebisethylenediamineamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{py}](\text{NO}_3)_3$. F. M. Jäger and P. Koets prepared **cobaltic bistriaminotriethylaminesexiesethylenediaminenitrate**, $[\text{Co}_3\text{en}_6(\text{C}_6\text{H}_{18}\text{N}_4)_2](\text{NO}_3)_4\text{H}_2\text{O}$, by treating the sulphate with barium nitrate. The reddish-brown crystals are monoclinic prisms with the axial ratios $a : b : c = 1.2327 : 1 : 0.5582$, and $\beta = 64^\circ 34'$. J. C. Dippel and F. M. Jäger prepared **cobaltic trisdiaminopentanenitrate**, $[\text{Co}\text{ptn}_3](\text{NO}_3)_3$, with $\alpha\beta\delta$ - and $\beta\beta\delta$ -diaminopentanes and J. C. Duff, **cobaltic succinobisethylenediaminenitrate**.

O. W. Gibbs and F. A. Genth⁴ prepared **cobaltic aquopentamminonitrate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{NO}_3)_3$, along with the hexammine nitrate, by the oxidation of ammoniacal soln. of cobaltous nitrate, followed by precipitation with nitric acid; O. W. Gibbs, and S. M. Jörgensen, by treating an ammoniacal, ice-cold soln. of the nitratopentamminonitrate with an excess of conc. nitric acid; A. Werner, by similarly treating the chloropentamminochloride; J. M. Krok, by the action of nitric acid on the corresponding iodosulphate; S. M. Jörgensen, by the action of nitric acid on the corresponding oxalate; and by J. C. Duff and E. J. Bills, by the action of nitric acid on the carbonatopentamminonitrate. The brick-red crystalline powder, monoclinic prisms or quadratic plates, was shown by J. D. Dana, and F. M. Jäger to have the axial ratios $a : b : c = 0.7984 : 1 : 1.0338$,

and $\beta=85^{\circ} 3'$. S. M. Jörgensen observed that at about 100° , the solid loses a mol. of water to form cobaltic nitratopentamminonitrate, and the same change occurs very slowly—within a year—at ordinary temp. A. B. Lamb and J. W. Marden, observed that the vap. press. of the aquopentamminonitrate is about 4 mm. at 25° . A. B. Lamb and J. P. Simmons found the mol. heat of soln. in water to be -15.38 Cals. at 25° . A. N. Nikolopulos, and R. Luther and A. N. Nikolopulos studied the absorption spectrum. A. Werner and A. Miolati measured the mol. conductivity at 25° ; and H. J. S. King observed the mol. conductivity, μ , of a mol of the salt in v litres of water, at 0° , to be :

v . . .	32	64	128	256	512	1024
μ . . .	163.0	179.0	197.6	212.2	225.9	238.0

The values at 25° were found by J. C. Duff to increase with time, and thus was attributed to the acceleration of the transformation of the aquo-nitrate into the nitrate-nitrate by contact with the platinum electrodes; the change is also favoured by the presence of sodium nitrate. S. M. Jörgensen found that 100 grms. of water, at 15° , dissolve about 5 grms. of the salt; N. S. Kurnakoff made observations on the subject; and F. Ephraim found that a sat., aq. soln., at 17.5° , contains 0.153 mol per litre; H. Pitzler, and A. Benrath and H. Pitzler studied the hydrolysis of the salt; and A. Benrath and H. Würzburger observed that in the presence of nitric acid the number of grams of cobalt in 100 grms. of water, at 11° , is as follows :

HNO_3 . . .	0.00	2.73	5.39	11.15	25.72 per cent.
Co . . .	0.785	0.298	0.132	0.087	0.067

The solubility thus decreases with increasing concentration of the nitric acid. The solid phase in contact with sat. soln. with concentrations up to 36 per cent. HNO_3 is the aquopentamminonitrate; with between 36 and 48 per cent. nitric acid, the solid phase is **cobaltic aquopentamminohydranonitrate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{NO}_3)_3 \cdot \text{HNO}_3$; and with over 48 per cent. of nitric acid, the nitrate-nitrate is formed, and the solid phase is $[\text{Co}(\text{HN}_3)_5(\text{NO}_3)](\text{NO}_3)_2 \cdot \text{HNO}_3$. S. M. Jörgensen prepared the aquopentamminohydranonitrate as a pale red solid, from a conc. nitric acid soln.; he found that at 103° , it loses a mol. each of water and nitric acid to form the nitrate-nitrate. F. Ephraim and W. Flügel treated a soln. of the corresponding iodide with 4 vols. of $2N\text{-HNO}_3$, and obtained octahedral crystals of what was thought to be either **cobaltic aquopentamminoiodonitrate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{NO}_3)_2\text{I}$, or else an isomorphous mixture. S. M. Jörgensen, and F. Ephraim and W. Flügel also reported **cobaltic aquopentamminosulphatonitrate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})](\text{SO}_4)\text{NO}_3$, by crystallization of the nitrate from dil. sulphuric acid. The red, octahedral crystals lose no weight at 100° ; a sat., aq. soln., at 19° , contains 0.0486 mol per litre. A. Benrath observed that aq. ammonia converts the aquopentamminonitrate into the hexamminonitrate. According to S. M. Jörgensen, a conc., aq. soln. of the aquo-nitrate gives precipitates with potassium iodide, chromate, dichromate, chloraurate, and ferrocyanide, with ammonium oxalate, hydrochloroplatinic and hydrobromoplatinic acids, sodium chloromercurate, pyrophosphate, and dil. sulphuric acid. No precipitate is formed with dil. hydrochloric or hydrobromic acid, mercuric chloride or sodium dithionate or hydrophosphate.

A. Werner prepared **cobaltic cis - aquobisethylenediamineamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{en}_2(\text{H}_2\text{O})](\text{NO}_3)_3$, by treating a sat., aq. soln. of the bromide with conc. nitric acid; the trans-salt separates out, leaving the cis-salt in soln. from which it is precipitated by the addition of alcohol and ether in the cold. The salt is freely soluble in water. The **cobaltic trans-aquobisethylenediamineamminonitrate** is formed, as just indicated, in red, prismatic crystals. M. Rosner prepared **cobaltic aquopyridinetetramminonitrate**, $[\text{Co}(\text{NH}_3)_4\text{py}(\text{H}_2\text{O})](\text{NO}_3)_3 \cdot \text{H}_2\text{O}$.

G. Vortmann⁵ prepared **cobaltic diaquotetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2](\text{NO}_3)_3$, by treating carbonatotetramminonitrate with cold, conc. nitric acid.

It was also prepared in this manner by S. M. Jörgensen, A. Benrath and K. Andreas, K. R. Lange, M. Rosner, and J. N. Brönsted and co-workers; F. Ephraim, by the action of conc. nitric acid on carbonatotetramminosulphate; and J. N. Brönsted and co-workers, by keeping the nitratoaquopentamminonitrate in aq. soln. According to F. Ephraim, the red, prismatic crystals *verpuffen* in the flame; and a sat., aq. soln., at 22°, contains 1.03 mol of the salt per litre. K. Andreas, and A. Benrath and K. Andreas found that the solubility diminishes down to a constant minimum value with increasing proportions of nitric acid in the soln. The diaquo-nitrate is not stable in contact with nitric acid, since it changes into the nitrato-nitrate, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO}_3)](\text{NO}_3)_2$. H. Pitzler, and A. Benrath and H. Pitzler studied the hydrolysis of the salt.

A. Werner and K. R. Lange prepared **cobaltic cis-diaquobisethylenediaminenitrate**, $[\text{Co en}_2(\text{H}_2\text{O})_2](\text{NO}_3)_2 \cdot \text{H}_2\text{O}$, by treating a cold, conc., aq. soln. of the bromide with conc. nitric acid, dissolving the product in water containing a little nitric acid, and precipitating the ice-cold soln. with alcohol. The red plates of the *monohydrate* lose their water over calcium chloride. They obtained **cobaltic trans-diaquobisethylenediaminenitrate**, by adding silver nitrate to a conc., aq. soln. of the corresponding bromide, at 25° to 30°, and cooling the soln.; or by treating an ice-cold conc., aq. soln. of the bromide with fuming nitric acid. The brownish-red needles crystallized from water acidulated with nitric acid, are not hydrated. A. Werner reported **cobaltic diaquobispyridinediamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{H}_2\text{O})_2](\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$, to be precipitated from an ice-cold, aq. soln. of the corresponding chloride, by means of conc. nitric acid, or ammonium nitrate. The red crystals are sparingly soluble in water, and the soln. has an acidic reaction. G. Lindenberg prepared **cobaltic diaquotrimethylenediaminenitrate**, $[\text{Co tr}_2(\text{H}_2\text{O})_2](\text{NO}_3)_3$.

G. Vortmann prepared **cobaltic triaquotriamminonitrate**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_3](\text{NO}_3)_3$, along with some other salts, by evaporating an ammoniacal soln. of cobaltous carbonate along with ammonium carbonate and then adding nitric acid for precipitation. S. M. Jörgensen obtained it, in deliquescent, carmine-red crystals, by evaporating an aged, aq. soln. of trinitratotriammine over sulphuric acid; and J. N. Brönsted and K. Volquartz, by adding the theoretical quantity of silver nitrate to dichloro-aquotriamminochloride. The constitution was discussed by A. Werner, and A. Werner and A. Miolati. G. Bredig noted that the mol. conductivity, μ , decreases as the NH_3 -group is replaced by a H_2O -group, so that with soln. containing a mol of the salt in v litres of water:

v	125	250	500	1000	2000
Hexammine	343.8	378.0	401.6	426.9	442.2
Aquopentammine	333.6	365.4	390.3	412.9	436.4
Diaquotetrammine	325.5	354.8	379.8	399.15	417.4
Triaquotriammine	317.7	339.0	361.1	383.8	392.6

J. N. Brönsted and K. Volquartz obtained **cobaltic tetraquodiamminonitrate**, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_4](\text{NO}_3)_3$, by adding a small excess over the theoretical proportion of silver nitrate to a soln. of green dichlorodiaquodiamminonitrate. The carmine-red soln. is unstable and gradually decomposes. The ionization constant, K , for the complex-ion $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_4]^{3+}$, approximates 0.00014 at 15°, and 0.00030 at 20°, and at infinite dilution, 0.00040 at 15°.

The CoA₅ or Pentammine Family

E. Frémy⁶ prepared **cobaltic nitratopentamminonitrate**, $[\text{Co}(\text{NH}_3)_5(\text{NO}_3)](\text{NO}_3)_2$, by heating an ammoniacal soln. of cobaltous nitrate which has been oxidized by air, with an excess of ammonium nitrate, or, according to O. W. Gibbs and F. A. Genth, with nitric acid. O. Künnel said that the product obtained by E. Frémy's process is a basic salt: $2\text{Co}_2\text{O}_4 \cdot 5\text{N}_2\text{O}_5 \cdot 20\text{NH}_3$. S. M. Jörgensen obtained it by heating aquopentamminonitrate, for many hours, at 100°, or, according to A. Benrath and K. Mienes, by heating it with conc. nitric acid, for many hours, on a water-bath. J. M. Krok and S. M. Jörgensen obtained this salt by oxidation with iodine in the following manner:

Twenty grms. of cobaltous carbonate are heated with the required amount of dil. nitric acid to convert it to nitrate, and 200 c.c. of conc., aq. ammonia are added. The boiling

soln. is then treated with a gram-atom of iodine for each gram-atom of cobalt, as indicated in connection with the preparation of the hexamminonitrate. After filtering off the hexamminonitrate from the cold soln., the filtrate is mixed with an excess of nitric acid, and heated 3 hrs. on the water-bath. When all the iodine has been expelled, the precipitate is filtered off; drained by suction, washed with water containing nitric acid, then with alcohol, and finally dried in a water-oven.

The red, octahedral crystals have a violet tinge, and, according to J. D. Dana, they are tetragonal bipyramids with the axial ratio $a:c=1:0.6216$. E. Birk gave 1.868 for the sp. gr. at $25^{\circ}/4^{\circ}$, and 176.7 for the mol. vol. A. B. Lamb and J. P. Simmons found the mol. heat of soln. in water, at 25° , to be 14.9 Cals. E. Valla, A. N. Nikolopoulos, and R. Luther and A. N. Nikolopoulos studied the absorption spectra of aq. soln. According to S. M. Jörgensen, 100 grms. of water at 16° dissolve 0.367 grm. of salt; and N. S. Kurnakoff, and J. N. Brönsted and co-workers studied the solubility of the salt in water, and in methanol. F. Ephraim observed that a sat. aq. soln. at 18° contains 0.0122 mol per litre. The nitratonitrate in aq. soln. is transformed into the aquo-nitrate. The process of aquation, $[\text{Co}(\text{NH}_3)_5(\text{NO}_3)]^{+} \rightarrow [\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]^{+}$, was found by A. B. Lamb and J. W. Marden to be a reaction of the first order, and at 25° , J. N. Brönsted calculated that in aq. soln. the velocity constant $k=0.000361$ at 15° ; 0.000757 at 20° ; and 0.00180 at 25° . The aquation is independent of the initial concentration of the complex ion, and of the degree of acidity. On the other hand, A. B. Lamb and J. W. Marden observed that the reaction is retarded up to 25 per cent. in acidic soln. A. B. Lamb and J. P. Simmons calculated for the mol. heat of the aquation, 480 cals. at 25° . The reaction was also discussed by A. Benrath, and R. Luther and A. N. Nikolopoulos; and R. Schwarz and K. Tede found that the reaction is favoured by exposure to light. S. M. Jörgensen said that the salt is decomposed when heated with water. S. M. Jörgensen observed that hot, dil. aq. ammonia dissolves the nitratonitrate, forming the aquopentamminonitrate. According to A. Benrath, aq. ammonia at 25° , converts the nitratopentamminonitrate into hexamminonitrate at a rate which is proportional to the concentration of the ammonia. In consequence of the aquation of the salt, S. M. Jörgensen stated that some reactions in aq. soln. reported for the nitratonitrate, really apply to the aquo-nitrate. S. M. Jörgensen observed that with a freshly-prepared, cold, sat. soln. of the nitratonitrate, precipitates are obtained with potassium iodide, chromate, dichromate, and ferricyanide, with sodium dithionate, picrate, and chloromercurate, and with hydrochloroplatinic and hydrobromoplatinic acids; but not with dil. sulphuric acid, potassium chloraurate, hydrofluosilicic acid, sodium pyrophosphate, or ammonium oxalate.

S. M. Jörgensen prepared **cobaltic nitratopentamminochloride**, $[\text{Co}(\text{NH}_3)_5(\text{NO}_3)]\text{Cl}_2$, in reddish-violet octahedra, by shaking one of the corresponding salts of the series, say the nitrate, with dil. hydrochloric acid (1:1). F. Ephraim observed that a sat. aq. soln., at 18° , contains 0.0279 mol per litre. S. M. Jörgensen observed that warm water converts the nitratochloride into the aquapentammine. The mol. conductivities of soln. with a mol of salt in 125, 500, and 200 litres of water, at 25° , were found by A. Werner and A. Miolati to be, respectively, 219.6, 247.6, and 285.2. There is also a marked increase in the conductivity with time—e.g., the mol. conductivity of a soln. of a mol of the salt in 250 litres changed from 250 to 290.2 in 24 hrs. This is taken to correspond with the aquation of the salt, a reaction studied by A. B. Lamb and J. W. Marden. J. N. Brönsted and co-workers studied the solubility in water, and in methanol. According to S. M. Jörgensen, if the salt be re-crystallized from hydrochloric acid, the chlorochloride is formed. The precipitate obtained by adding sodium chloromercuriate in the presence of sodium or ammonium chloride, is **mercuric cobaltic nitratopentamminotetrachloride**, $[\text{Co}(\text{NH}_3)_5(\text{NO}_3)]\text{Cl}_2 \cdot \text{HgCl}_2$. The scarlet-red prisms are decomposed by hydrochloric acid (1:1) into chloropentamminochloride and mercuric chloride. J. M. Krok described **mercuric cobaltic nitratopentammineachloride**, $[\text{Co}_2(\text{NH}_3)_{10}(\text{NO}_3)_3](\text{HgCl}_3)_3$.

S. M. Jørgensen prepared **cobaltic nitratopentamminobromide**, $[\text{Co}(\text{NH}_3)_5(\text{NO}_3)]\text{Br}_2$, in reddish-violet crystals, by a process analogous to that employed for the chloride. F. Ephraim found that a sat., aq. soln., at 18° , contains 0.0159 mol per litre; and A. Werner and A. Miolati found that the mol. conductivities of a soln. of a mol of the salt in 250, 500, and 2000 litres of water, at 25° , are, respectively, 270.9, 288.1, and 316.6; and that with a soln. with $v=250$, the mol. conductivity increases in 24 hrs. from 270.9 to 309.5. This corresponds with the aqution of the salt. J. N. Brønsted and co-workers studied the solubility in water and in methanol. S. M. Jørgensen obtained reddish-violet crystals of **cobaltic nitratopentamminiodide**, $[\text{Co}(\text{NH}_3)_5(\text{NO}_3)]\text{I}_2$, by adding potassium iodide to a soln. of the corresponding nitrate. F. Ephraim found that a sat., aq. soln., at 18° , contains 0.0271 mol per litre. J. N. Brønsted and co-workers studied the solubility in water and in methanol. S. M. Jørgensen prepared violet needles of **cobaltic nitratopentamminosulphate**, $[\text{Co}(\text{NH}_3)_5(\text{NO}_3)]\text{SO}_4 \cdot \text{H}_2\text{O}$, by adding alcohol to a soln. of the chloride in dil. sulphuric acid. Only a trace of water is lost from the monohydrate at 100° , but all is expelled at 135° to 140° . F. Ephraim found that a sat., aq. soln., at 18° , contains 0.0050 mol per litre.

A. Werner prepared **cobaltic cis-nitratobisethylenediamineamminonitrate**, $[\text{Co}(\text{NH}_3)_2(\text{NO}_3)](\text{NO}_3)_2$, by evaporating, on a water-bath, a mixture of conc. nitric acid and aquobisethylenediamineamminonitrate. The orange-yellow crystals are converted by conc. ammonia into bisethylenediaminediamminonitrate. The corresponding **cobaltic trans-nitratobisethylenediamineamminonitrate**, $[\text{Co}(\text{NH}_3)_2(\text{NO}_3)](\text{NO}_3)_2 \cdot \text{H}_2\text{O}$, is obtained by treating trans-aquo-nitrate with nitric acid. L. Cohn prepared **cobaltic nitratobisethylenediamineamminobromide**, $[\text{Co}(\text{NH}_3)_2(\text{NO}_3)]\text{Br}_2$.

J. N. Brønsted obtained **cobaltic nitratotetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO}_3)](\text{NO}_3)_2$, by warming 10 grms. of the carbonatotetramminonitrate with 50 c.c. of 10 per cent. nitric acid, adding 50 c.c. of conc. nitric acid to the clear soln. at 100° , cooling in ice for 15 mins., and washing the crystals with alcohol. The salt is purified by dissolving 10 grms. in 200 c.c. of 0.1N- HNO_3 , and adding 50 c.c. conc., nitric acid to the ice-cold liquid. The salt obtained by G. Vortmann and co-workers, and M. Rosner, by precipitation from an aq. soln. of the carbonato-nitrate with nitric acid, is considered by J. N. Brønsted to be the diaquotetramminonitrate. A. Werner and A. Miolati found the mol. conductivities of soln. of a mol. of the salt in 128, 512, and 2048 litres of water, at 25° , are, respectively, 306.1, 353.8, and 388.5. J. N. Brønsted, and J. N. Brønsted and R. Livingston found that the conductivity of the soln. increases with its age, corresponding with the transformation of the nitratotetramminonitrate into the diaquotetramminonitrate. The aqution: $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO}_3)]^+ + \text{H}_2\text{O} = [\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]^{++} + \text{NO}_3^-$, is dependent on the acidity of the soln., and the reaction is of the first order if the H^+ -ion is not less than about 0.001N. The velocity constant, k , of the aqution in acidic soln. is $0.0376 + 0.04107/[\text{H}^+]$ at 15° , and at 20° , it is $0.03160 + 0.0432/[\text{H}^+]$. H. Pitzler studied the equilibrium conditions in the system: $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO}_3)](\text{NO}_3)_2 - \text{NH}_3 - \text{H}_2\text{O}$.

O. W. Gibbs and F. A. Genth⁷ obtained what they regarded as a basic pentammino-salt, **cobaltic hydroxypentamminonitrate**, $[\text{Co}(\text{NH}_3)_5(\text{OH})](\text{NO}_3)_2 \cdot \text{H}_2\text{O}$, as a separation from a mixture of an aq. soln. containing nitratopentamminonitrate, ammonium nitrate, and aq. ammonia. A. Werner prepared it by warming aquopentamminonitrate with 5 times its weight of conc., aq. ammonia, and precipitating with alcohol; it can be re-crystallized by adding alcohol to the soln. in aq. ammonia. The violet-red scales of the *monohydrate* lose their water at 80° . The violet, aq. soln. has an alkaline reaction. It liberates ammonia from ammonium salts, to form aquopentammine-salts; with acetic anhydride it forms the acetatopentammine-salt; and with carbon dioxide, the hydrocarbonato-nitrate. H. J. S. King found the mol. conductivity of soln. with a mol of the salt in 128 and 1042 litres of water, at 0° , to be, respectively, 124.2 and 143.4; and of a mol of the salt in 32, 128, and 1024 litres of water, at 25° , respectively, 196.5, 229.5, and 266.2. E. Rosenbohm

gave -0.197×10^{-6} mass unit for the magnetic susceptibility, and the magnetic properties were studied by W. Biltz, and L. C. Jackson.

A. Werner, and M. Rosner prepared **cobaltic hydroxyaquotetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{OH})](\text{NO}_3)_2$, as a reddish-violet mush of tabular crystals, by treating the corresponding bromide with sodium nitrate and filtering rapidly. The salt is very unstable in aq. soln., forming black hexol-dodecamminonitrate. H. J. S. King found the eq. conductivity, at 0° , to be :

ν	.	.	.	32	64	128	256	512	1024	∞
λ	.	.	.	99.8	109.9	117.5	123.2	128.1	131.8	141.7

M. Rosner prepared **cobaltic hydroxybispyridinetriamminonitrate**, $[\text{Co}(\text{NH}_3)_3\text{py}_2(\text{OH})](\text{NO}_3)_2 \cdot 5\text{H}_2\text{O}$.

A. Werner prepared **cobaltic cis-hydroxyaquobisethylenediaminenitrate**, $[\text{Co}(\text{en})_2(\text{H}_2\text{O})(\text{OH})](\text{NO}_3)_2$, by adding potash-lye to hexol-sexiesethylenediaminenitrate. Hydrated cobalt oxide first separates from the soln., and afterwards the required nitrate. M. Rosner prepared **cobaltic hydroxypyridinetriamminonitrate**, $[\text{Co}(\text{NH}_3)_3\text{py}(\text{HO})](\text{NO}_3)_2$. A. Werner obtained **cobaltic hydroxyaquobispyridinediamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{py}_2(\text{H}_2\text{O})(\text{OH})](\text{NO}_3)_2$, by adding a sat., aq. soln. of sodium nitrate to a soln. of the corresponding chloride in 10 per cent. acetic acid. The pale red needles have a bluish tinge; they are sparingly soluble in water, and the aq. soln. has a feebly alkaline reaction.

H. Seibt reported **cobaltic cis-fluobisethylenediamineamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{F}](\text{NO}_3)_2$, to be formed as a red, crystalline powder, by treating the corresponding chloride with ammonium nitrate; and then adding alcohol to an aq. soln. of the salt.

A. Hiendlmayr⁸ prepared **cobaltic fluopentamminonitrate**, $[\text{Co}(\text{NH}_3)_5\text{F}](\text{NO}_3)_2$, by adding dil. nitric acid to a sat. soln. of the corresponding fluoride or chloride. The violet-red powder is soluble in water, and in-hydrochloric acid.

S. M. Jörgensen, and R. Pers prepared **cobaltic chloropentamminonitrate**, $[\text{Co}(\text{NH}_3)_5\text{Cl}](\text{NO}_3)_2$, by adding conc. nitric acid to a soln. of the corresponding chloride or sulphate, and cooling to zero. Small, red, octahedral crystals are formed. S. M. Jörgensen observed no loss in weight occurs when the salt is heated to 110° , but there is a vigorous reaction at a higher temp. O. Stelling studied the X-ray absorption spectrum. A. Werner and A. Miolati found the mol. conductivities of soln. of a mol of the salt in 64, 256, and 2048 litres, at 25° , to be, respectively, 191.09, 212.8, and 232.6. A. B. Lamb and J. W. Marden found that the conductivity of the soln. changes with time, owing to aqutation. The velocity constant of the aqutation, k , corresponds with a reaction of the first order, and $k=0.0455$. R. Kremann studied the transport numbers; and L. C. Jackson, the magnetic properties. E. Rosenbohm gave -0.248×10^{-6} mass unit for the magnetic susceptibility. J. W. Williams studied the activity coeff. S. M. Jörgensen said that the neutral, aq. soln. partially decomposes when boiled, but not so with the feebly acidic soln. J. N. Brönsted and co-workers studied the solubility of the salt in water, and in methanol. F. Ephraim and W. Flügel observed no precipitation with potassium nitrilosulphonate, but there is one with potassium hydroxylamine-iso-disulphonate.

J. C. Duff prepared pentamminonitrates with the dibasic radicles, X, of malonic, malic, phthalic, citraconic, itaconic, glutaric, and adipic acids of the types :

S. M. Jörgensen prepared **cobaltic cis-chlorobisethylenediamineamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Cl}](\text{NO}_3)_2$, by treating the corresponding chloride with dil. nitric acid, and then with alcohol. The pale carmine-red needles are readily soluble in water. The absorption spectrum was studied by A. Gordienko, and J. Angerstein. A. Werner and C. Hertý found that the mol. conductivities of soln. with a mol of the salt in 125, 500, and 2000 litres of water, at 25° , were, respectively, 204.90, 227.04, and 247.91. S. M. Jörgensen found that silver nitrate gives a precipitate only after the aq. soln. of the salt has been boiled. A. Werner obtained **cobaltic trans-chlorobisethylenediamineamminonitrate**, by precipitating with alcohol a nitric acid soln. of the corresponding chloride. E. Berl prepared **cobaltic chlorobisethylenediaminehydroxylamine-nitrate**, $[\text{Co}(\text{NH}_2\text{OH})_2\text{en}_2\text{Cl}](\text{NO}_3)_2$. J. Meisenheimer

and E. Kiderlen obtained **cobaltic trans-chloroallylaminebisethylenediaminenitrate**, $[\text{Co en}_2(\text{C}_3\text{H}_5\text{NH}_2\text{Cl})(\text{NO}_3)_2]$, in six-sided prisms, by adding nitric acid to a soln. of the corresponding chloride. The crystals are dichroic—violet and green. They also prepared **cobaltic chloroanilinebisethylenediaminenitrate**, $[\text{Co en}_2(\text{C}_6\text{H}_5\text{NH}_2\text{Cl})(\text{NO}_3)_2]$, by adding an excess of sodium nitrate to a cold, aq. soln. of the corresponding chloride. The dark red crystals are easily soluble in water, and in conc. hydrochloric acid, but sparingly soluble in dil. nitric acid. They obtained **cobaltic chlorotoluidinebisethylenediaminechloronitrate**, $[\text{Co en}_2(\text{C}_7\text{H}_7\text{NH}_2\text{Cl})(\text{NO}_3)\text{Cl}]$, by the action of sodium nitrate on an aq. soln. of the corresponding chloride. The six-sided, violet-red prisms are feebly dichroic, and sparingly soluble in cold water. They prepared **cobaltic chlorobenzylaminebisethylenediaminenitrate**, $[\text{Co en}_2(\text{C}_7\text{H}_7\text{NH}_2\text{Cl})(\text{NO}_3)_2]$, by adding sodium nitrate to a soln. of the chloride. Rose-red plates are precipitated from the aq. soln. at 50° to 60° . R. Vogel obtained **cobaltic chloropyridinebisethylenediaminenitrate**, $[\text{Co en}_2\text{pyCl}](\text{NO}_3)_2$; and C. Duval, **cobaltic tartaropentamminonitrate**, $[\text{Co}(\text{NH}_3)_5(\text{C}_4\text{H}_4\text{O}_6)]\text{NO}_3$.

S. M. Jørgensen⁹ prepared **cobaltic cis-chloroaquatetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{OCl})(\text{NO}_3)_2]$, by triturating the corresponding chloride with cold water, acidulated with nitric acid, for complete soln., and precipitating the salt by nitric acid. The violet, rhombic crystals are decomposed at 100° —nitratopentamminochloride is one of the decomposition products. A. Werner, and A. Werner and A. Grün obtained **cobaltic chloroaquotriamminonitrate**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})_2\text{Cl}](\text{NO}_3)_2$, in bluish-violet needles, by adding nitric acid to a cold soln. of the corresponding chloride.

S. M. Jørgensen¹⁰ prepared **cobaltic bromopentamminonitrate**, $[\text{Co}(\text{NH}_3)_5\text{Br}](\text{NO}_3)_2$, by washing the corresponding bromide with water acidulated with sulphuric acid, at 30° to 40° , into cold, conc. nitric acid. The dark violet, octahedral crystals have a sp. gr. of 1.965 at $17.1^\circ/4^\circ$; and I. Posen, and R. Lorenz and I. Posen gave 1.9632 for the sp. gr. in vacuo, and found the eq. conductivity of soln. with a gram-equivalent of the salt in 128, 512, and 1024 litres, at 3.6° to 4.2° , to be, respectively, 71.28, 76.89, and 78.29; and at 18° , 101.5, 108.6, and 109.5, when the eq. conductivity at infinite dilution is 116.4 at 18° . S. M. Jørgensen found the salt is soluble in water, and insoluble in dil. nitric acid, and in alcohol. J. N. Brønsted and A. Petersen found that a sat., aq. soln. contained 0.010 mol per litre at 20° ; and F. Ephraim, 0.0107 mol per litre at 20° . J. N. Brønsted and co-workers studied the solubility of the salt in water and in methanol. S. M. Jørgensen observed that silver nitrate precipitates no silver bromide from the freshly-prepared soln., but after standing for some time, or boiling for a short time, an opalescence appears, owing to the formation of silver bromide as the bromo-nitrate forms the aquo-nitrate. Hydrobromic and hydrochloric acids form the corresponding bromide or chloride. H. J. S. King prepared **cobaltic nitratoaquatetramminosulphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})(\text{NO}_3)]\text{SO}_4$.

E. Schmidt, and A. Werner and W. E. Boës prepared **cobaltic cis-bromobisethylenediamineamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Br}](\text{NO}_3)_2$, by triturating the corresponding bromide with nitric acid, and re-crystallizing from its aq. soln. The dark reddish-violet, columnar crystals are almost black, and sparingly soluble in water. A. Werner and E. Scholze obtained the *dextro*-salt as a *monohydrate* from the corresponding camphorbromosulphonate. The dark violet crystals, in 0.08 per cent. aq. soln., have a sp. rotation $[\alpha] = 45^\circ$ for red-light. If nitric acid be dropped into a cold, sat., aq. soln. of the bromide, **cobaltic cis-bromobisethylenediamineamminobromonitrate**, $[\text{Co}(\text{NH}_3)_2\text{en}_2\text{Br}](\text{NO}_3)\text{Br}$, is formed in reddish-violet crystals. A. Werner and W. E. Boës also prepared **cobaltic trans-bromobisethylenediamineamminonitrate**, as a *monohydrate*, by triturating lithium nitrate with the bromide and a little water. C. S. Borzekowsky prepared **cobaltic bromohydroxylaminebisethylenediaminenitrate**, $[\text{Co}(\text{NH}_3)_2\text{en}_2(\text{NH}_2\text{OH})\text{Br}](\text{NO}_3)_2$.

A. Werner and A. Wolberg¹¹ prepared **cobaltic cis-bromoaquatetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Br}](\text{NO}_3)_2$, by triturating the corresponding bromide, six times with dil. nitric acid (4 : 1), and washing the residue with alcohol and ether. The reddish-violet crystals are easily soluble in water. E. Schmidt, and A. Werner and E. Schmidt obtained **cobaltic cis-bromoaquobisethylenediaminenitrate**, $[\text{Co en}_2(\text{H}_2\text{O})\text{Br}](\text{NO}_3)_2$, as a bluish-violet crystalline powder, by adding sodium nitrate to a conc., aq. soln. of the corresponding bromide.

J. Sand and G. Bökman obtained **cobaltic iodopentamminonitrate**, $[\text{Co}(\text{NH}_3)_5\text{I}](\text{NO}_3)_2$, by triturating black nitrosopentamminonitrate with an alcoholic soln. of iodine, and boiling the green product with 20 per cent. nitric acid. A. Werner obtained the salt by mixing the nitro-nitrate with the iodo-nitrate, but preferably by triturating the corresponding dichromate or iodide with ammonium nitrate and a little water, and precipitating the salt from its aq. soln. by conc. nitric acid. J. Angerstein studied the absorption spectrum of aq. soln. The yellowish-green, crystalline powder is sparingly soluble in water—F. Ephraim added that a sat., aq. soln., at 20° , contains 0.00217 mol of the salt. A. Werner found that when warmed with silver nitrate in dil. acetic acid soln., the iodo-nitrate is converted into aquonitrate, with the precipitation of silver iodide.

S. M. Jörgensen¹² prepared **cobaltic sulphatotetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{SO}_4)]\text{NO}_3$, by treating an aq. soln. of the hydrosulphate with ammonium nitrate. The reddish-violet, four- or six-sided prisms lose no weight over sulphuric acid, or at 100° . F. Ephraim and W. Flügel observed that the sat., aq. soln. has 0.0273 mol of salt per litre at 20° ; and J. N. Brönsted and A. Peterson found 0.0260 mol per litre at the same temp. A. Werner and A. Miolati found the mol. conductivities of soln. with a mol of salt in 64, 256, and 1024 litres of water, at 25° , were, respectively, 78.63, 89.73, and 101.6. J. C. Duff added that the conductivity increases a little with time. P. Job found that when the soln. is titrated electrometrically with soln. of barium hydroxide, the curve is regular and shows no inflexion, and this is taken to indicate that no mols. of water are present in the radical. S. M. Jörgensen observed that with the aq. soln., barium chloride gives a precipitate of barium sulphate only after the soln. has been boiled; and dil. nitric acid, potassium iodide, and dichromate, and hydrochloroplatinic acid give crystalline precipitates of the corresponding salts.

F. Ephraim and W. Flügel prepared **cobaltic sulphatoaquotriamminonitrate**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})(\text{SO}_4)]\text{NO}_3$, by adding ammonium nitrate to a conc., aq. soln. of the corresponding chloride. G. Vortmann and O. Blasberg also prepared this salt. The rose-red, prismatic crystals lose a mol of water slowly at 100° . F. Ephraim and W. Flügel found that a sat., aq. soln. has 0.0712 gram-atom of Co per litre at 20° . P. Job studied the electrometric titration of the salt with barium hydroxide. N. Goslings prepared **cobaltic carbonatotetramminonitrate**, $[\text{Co}(\text{NH}_3)_4\text{CO}_3]\text{NO}_3 \cdot \text{H}_2\text{O}$; and K. J. Pedersen studied the rate of decomposition of the salt.

The CoA_4 or Tetrammine Family

H. J. S. King¹³ prepared **cobaltic dihydroxytetramminonitrate**, $[\text{Co}\{\text{Co}(\text{NH}_3)_4(\text{OH})_2\}_3](\text{NO}_3)_6$; and E. Birk obtained **cobaltic dinitratotetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{NO}_3)_2]\text{NO}_3 \cdot \text{H}_2\text{O}$, by boiling and cooling a soln. of carbonatotetramminonitrate in nitric acid. The red crystals of the *monohydrate* lose their water at 90° to 95° . The sp. gr. of the monohydrate is 1.914 at $25^\circ/4^\circ$, and the mol. vol. 173.0; whilst the sp. gr. of the anhydrous salt is 1.939 at $25^\circ/4^\circ$, and the mol. vol. is 161.5. This salt resembles one prepared by G. Vortmann in 1885. W. Schramm obtained the salt by the action of malonic acid on the diaquotetramminonitrate, or on the hydroxyaquotetramminonitrate. Oxalic acid converts the salt into the oxalatonitrate; but malonic acid has no action. A. Werner and C. Kreutzer obtained **cobaltic dinitratobisethylenediaminehydronitrate**, $[\text{Co en}_2(\text{NO}_3)_2]\text{NO}_3 \cdot \text{HNO}_3$, in dark red, triclinic crystals, by evaporating to dryness a soln. of cis-dinitritobisethylenediaminenitrate with conc. nitric acid, dissolving the residue in conc. nitric acid, and evaporating over potassium hydroxide. When the hydronitrate is exposed to air, or confined over potassium hydroxide, it furnishes a greyish-brown powder of **cobaltic dinitratobisethylenediaminenitrate**, $[\text{Co en}_2(\text{NO}_3)_2]\text{NO}_3$, which is also prepared by evaporating the aq. soln. of the hydronitrate with conc. aq. ammonia, or by heating the hydrosulphate with liquid ammonia. The *monohydrate* was reported by W. Schramm to be formed by the action of malonic acid

on the diaquo-nitrate. The monohydrate decomposes slowly at 120° , and explosively above that temp.

H. Seibt¹⁴ prepared **cobaltic cis-difluobisethylenediaminenitrate**, $[\text{Co en}_2\text{F}_2]\text{NO}_3$, in green plates, by evaporating trans-difluobisethylenediaminefluoride with water, mixing the cold, conc., aq. soln. with ammonium nitrate, and re-crystallizing the precipitate from water by the addition of alcohol. M. L. Ernsberger and W. R. Brode, and A. Gordienko studied the absorption spectrum.

A. Werner prepared **cobaltic cis-dichlorotetramminonitrate**, $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{NO}_3$, by rubbing up the dithionate, with ammonium chloride, and then treating the cold, aq. soln. with nitric acid, and washing with alcohol and ether. The bluish-violet, six-sided plates are freely soluble in water and lose no weight over phosphorus pentoxide. A. Werner and A. Klein obtained **cobaltic trans-dichlorotetramminonitrate**, in green needles, by treating the hydrosulphate with conc. nitric acid. The salt was prepared by G. Vortmann and considered by him to be the monohydrate. O. Stelling studied the X-ray absorption spectrum. A. Werner and A. Miolati found that the mol. conductivity, at 25° , increases for a dilution of 512 litres per mol, from 133.5 to 323.0 in 1 hour, and the salt is completely transformed into the diaquo-nitrate. L. Tschugaeff made some observations on this subject. E. Rosenbohm found the magnetic susceptibility to be -0.175×10^{-6} mass unit; and L. C. Jackson, and W. Biltz studied the magnetic properties. J. N. Brönsted and A. Petersen found that a sat., aq. soln., at 0° , contains 0.00383 mol per litre; they also studied the effect of the addition of other salts on the solubility of the dichloronitrate. A. Werner and A. Klein observed that silver nitrate gives a precipitate of silver chloride, after it has been warmed.

A. Werner and R. Feenstra prepared **cobaltic trans-dichloroquaterpyridinenitrate**, $[\text{Co py}_4\text{Cl}_2]\text{NO}_3$, by treating a soln. of the chloride with nitric acid; dissolving in water at 40° to 50° , and precipitating with conc. nitric acid; and re-crystallizing from dil. acetic acid. The green needles of the monohydrate lose their water of hydration over phosphorus pentoxide. T. S. Price obtained an air-dried salt with 4 to 5 mols. of water of hydration. The salt loses pyridine in a drying-oven. S. M. Jörgensen obtained violet prisms of **cobaltic cis-dichlorobisethylenediaminenitrate**, $[\text{Co en}_2\text{Cl}_2]\text{NO}_3$, by the action of dil. nitric acid on the corresponding chloride. O. Stelling studied the X-radiograms. The mol. conductivity of an aq. soln. with 150 litres per mol, was found by A. Werner and C. Herty to suffer very little change at 0° with time, but at 25° the conductivity changed from 97.38 to 123.45 in 19 mins., in consequence of the ionization of chlorine-ions liberated during the aq. solution of the complex salt. The subject was discussed by L. Tschugaeff, W. D. Harkins and co-workers, and E. Petersen. E. Rosenbohm found the magnetic susceptibility to be -0.287×10^{-6} mass unit; and the magnetic properties were also studied by L. C. Jackson. P. Larisch, and A. Werner and P. Larisch found that 100 c.c. of water, at 7° , dissolve 0.566 gm. of the salt. S. M. Jörgensen observed that the salt is less soluble than the corresponding chloride, and that silver nitrate gives no precipitate with the cold soln., but a precipitate of silver chloride is produced if the soln. has stood for some time, or if it has been boiled. Hydrochloroplatinic acid gives a precipitate of chloroplatinate. A. Werner and G. Tschernoff obtained the *dextro*-salt and the *levo*-salt, in violet crystals, from the corresponding camphorbromosulphonates and nitric acid. A 0.25 per cent. soln. of the salt has the sp. rotations $[\alpha] = \pm 164^{\circ}$. S. M. Jörgensen prepared **cobaltic trans-dichlorobisethylenediaminenitrate**, $[\text{Co en}_2\text{Cl}_2]\text{NO}_3$, by adding nitric acid to an aq. soln. of the corresponding chloride. The emerald-green crystals do not dissolve in water so readily as the chloride; according to P. Larisch, and A. Werner and P. Larisch, 100 c.c. of water, at 7° , dissolve 0.346 gm. of the salt. O. Stelling studied the X-radiograms. A. Werner and C. Herty found that the mol. conductivity of a soln. with 125 litres per mol, at 0° , suffers very little change with time, but at 25° the conductivity rises from 95.44 to 122.97 in 34 mins., in consequence of the aq. solution of the salt. The subject was discussed by L. Tschugaeff. According to S. M. Jörgensen, the colour of the soln. changes to violet-red when it is boiled, in consequence of the formation of the chloro-aquonitrate; but on cooling, its green colour returns, in consequence of the re-formation of the dichloro-nitrate. Silver nitrate precipitates no silver chloride from the cold soln. A. Werner and A. Fröhlich prepared **cobaltic trans-dichlorobispropylenediaminenitrate**, $[\text{Co pn}_2\text{Cl}_2]\text{NO}_3 \cdot \text{H}_2\text{O}$, in matte green crystals, by triturating the corresponding chloride in a little water. The monohydrate loses its water of hydration in the desiccator. They also found that silver **cobaltic dichlorobispropylenediaminesulphononitrate**, $2[\text{Co pn}_2\text{Cl}_2]\text{SO}_4\text{Ag} \cdot \text{AgNO}_3$, is formed, in malachite-green scales, on mixing cold, conc., aq. soln. of the component salts. The salt readily dissolves in water, and becomes bluish-

red on keeping—possibly owing to the formation of silver chloride, say $2\text{Co}[\text{pn}_2\text{Cl}(\text{AgCl})]\text{SO}_4 \cdot \text{AgNO}_3$. A. Werner obtained sparingly soluble **cobaltic dichlorobispyridinediamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{py}_2\text{Cl}_2]\text{NO}_3$, by adding nitric acid to a soln. of the chloride. C. Rix, and A. Werner and F. Chaussy prepared **cobaltic trans-dichloroethylenediaminediamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{enCl}_2]\text{NO}_3$, as a green precipitate, on adding, drop by drop, 1 : 1-nitric acid to a conc. soln. of the corresponding chloride. M. L. Ernsberger and W. R. Brode studied the absorption spectrum of **cobaltic chlorobromobisethylenediaminenitrate**.

S. M. Jörgensen¹⁵ obtained **cobaltic dichloroaquotriamminonitrate**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{Cl}_2]\text{NO}_3$, by treating an ice-cold soln. of the hydrosulphate with dil. nitric acid; and A. Werner, by treating the chloride in a somewhat similar way. The dark green crystals are slightly dichroic—bluish-green and pale red—and the green, aq. soln. changes to blue when kept for some time. A. Werner and A. Grün obtained **cobaltic dichloroaquoethylenediamineamminonitrate**, $[\text{Co}(\text{NH}_3)_2\text{en}(\text{H}_2\text{O})\text{Cl}_2]\text{NO}_3$, by the action of nitric acid (1 : 4) on the chloride. The green crystals are freely soluble in water.

A. Werner prepared **cobaltic dichlorodiaquodiamminonitrate**, $[\text{Co}(\text{NH}_3)_2(\text{H}_2\text{O})_2\text{Cl}_2]\text{NO}_3$, by treating the hydrosulphate with cold, conc. nitric acid. The dark green, crystalline powder forms a green soln. with water, which soon becomes blue. The dry salt decomposes on keeping.

A. Werner and A. Wolberg prepared **cobaltic trans-dibromotetramminonitrate**, $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{NO}_3$, by treating a cold soln. of the chloride with nitric acid. The pale green, prismatic crystals dissolve in water to form a soln. which soon changes into an aquo-salt. A. Werner and co-workers prepared **cobaltic cis-dibromobisethylenediaminenitrate**, $[\text{Co en}_2\text{Br}_2]\text{NO}_3$, in greyish-violet crystals, by adding sodium nitrate to a cold, sat., aq. soln. of the bromide. S. M. Jörgensen prepared **cobaltic trans-dibromobisethylenediaminenitrate**, $[\text{Co en}_2\text{Br}_2]\text{NO}_3$, by treating a soln. of the bromide, acidified with sulphuric acid, with dil. nitric acid (1 : 2). The rhombic, acicular crystals are isomorphous with those of the trans-dichloronitrate. E. Petersen, A. Werner and C. Herty, and W. D. Harkins and co-workers discussed the lowering of the f.p. of aq. soln., and the electrical conductivity. According to S. M. Jörgensen, the salt is sparingly soluble in water, and forms a yellowish-green soln.; the soln. gives precipitates with hydrochloroplatinic acid, sodium chloromercurate, and potassium dichromate. Silver nitrate gives a precipitate of silver bromide with an aged soln., but not with one freshly prepared. S. Berkman and H. Zocher, and G. Depold studied the magnetic constants of **cobaltic carbonatotetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{CO}_3)]\text{NO}_3 \cdot \frac{1}{2}\text{H}_2\text{O}$.

E. Böhm¹⁶ obtained **cobaltic fluohydroxytetramminonitrate**, $[\text{Co}(\text{NH}_3)_4(\text{OH})\text{F}]\text{NO}_3$, in purple-red, acicular or prismatic crystals, along with the hexamminofluonitrate, by the action of hydrofluoric acid and an excess of aq. ammonia, on cobaltous nitrate. H. Fischlin also prepared **cobaltic chlorohydroxybisethylenediaminenitrate**, $[\text{Co en}_2(\text{OH})\text{Cl}]\text{NO}_3$, by the action of lithium nitrate on the corresponding bromide—the *dextro*-salt, or the *lævo*-salt. The sp. rotation of the *dextro*-salt is $[\alpha] = 530^\circ$, and of the *lævo*-salt, -542° in Na-light. J. Lifschitz studied the anomalous dispersion. A. Werner prepared dark violet needles of **cobaltic cis-bromochlorobisethylenediaminenitrate**, $[\text{Co en}_2\text{ClBr}]\text{NO}_3$, by treating a cold soln. of the bromide with ammonium nitrate. A. Werner and G. Tschernoff obtained the *dextro*-salt, and the *lævo*-salt by the action of conc. nitric acid on the corresponding camphorbromosulphonates. The dark grey powder, 45 mins. after being dissolved in water, becomes inactive. The sp. rotation of a soln. of the *dextro*-salt is $[\alpha] = 144^\circ$, and of the *lævo*-salt, -152° . A. Werner also prepared **cobaltic trans-bromochlorobisethylenediaminenitrate**, by heating chloroaquobisethylenediaminebromide for some hours at 110° , triturating the mixture of violet cis- and green trans-bromochlorobromide with cold water and saturating the green soln. with ammonium nitrate. The violet cis-bromochlorobromide does not dissolve. The pale green plates are sparingly soluble in water.

A. Werner and A. Grün obtained pale green **cobaltic bromochloroaquotriamminonitrate**, $[\text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})\text{ClBr}]\text{NO}_3$, by adding conc. nitric acid to a cold,

aq. soln. of the bromide; and similarly with pale green **cobaltic bromochloro-aquoethylenediamineamminonitrate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})\text{ClBr}]\text{NO}_3$.

R. Luther and H. Frieser studied the decomposition of **cobaltic trinitratotriammine**, $[\text{Co}(\text{NO}_3)_3(\text{NH}_3)_3]$, in acidic soln., in light and in darkness.

Complexes with Two or More Carbon Atoms

E. Frémy¹⁷ prepared **cobaltic peroxo-decamminotetranitrate**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5](\text{NO}_3)_4 \cdot 2\text{H}_2\text{O}$, in dark brown prisms, by the aerial oxidation of a conc. ammoniacal soln. of cobaltous nitrate. The salt was also prepared by G. Vortmann, C. Schwenk, and O. W. Gibbs. A. Werner and A. Mylius recommend the following process for preparing what was formerly called *oxycobaltamine nitrate*:

Cobalt nitrate (200 grms.) is dissolved in water (250 grms.), the boiling solution poured into ammonia (850 grms., sp. gr. = 0.927), and the mixture heated for about 5 minutes; when cold, the mixture is filtered and treated with a slow current of air as long as a thick, crystalline precipitate is formed. The crystals of the peroxo-nitrate are collected, washed with ammonia and alcohol, and dried by pressing between filter-paper.

The brown crystals sometimes become green when dried; and when formed in the presence of ammonium nitrate, the prisms are dark olive-green, almost black. A. Werner and A. Mylius, and A. Mylius observed that the salt decomposes at 110° , and G. Vortmann, that it explodes at 200° . E. Feytis gave 0.092×10^{-6} mass unit for the magnetic susceptibility. E. Frémy observed that the salt is decomposed by sulphuric acid, potash-lye, or water, in the cold, and oxygen is given off. G. Vortmann noted that it decolorizes soln. of permanganates. According to A. Werner and A. Mylius, after heating at 110° until the weight is constant, the product, when treated with a small quantity of water, and the brown filtrate mixed with conc. hydrochloric acid, yields, after a time, a brown precipitate consisting of a mixture of melanocobalt chloride, hexamminochloride, and aquopentamminochloride. The melanocobalt chloride, which is formed in small quantities only, remains undissolved when the mixture is treated with water. The soln. containing the other two salts is boiled with hydrochloric acid, when the chloropentamminochloride is precipitated from the hot soln., and the hexamminochloride separates on cooling. This operation must be repeated several times in order to effect a complete separation. When the brown, aq. soln. obtained from the product from the peroxo-decamminonitrate, after heating at 110° , is treated with nitric instead of with hydrochloric acid, hexamminonitrate is obtained, and on adding hydrochloric acid to the filtrate from this salt, chloropentamminochloride is precipitated. G. Vortmann obtained **cobaltic peroxo-decamminohydrionitrate**, $[\text{Co}_2(\text{O}_2)(\text{NH}_3)_{10}](\text{NO}_3)_4 \cdot \text{HNO}_3 \cdot 3\text{H}_2\text{O}$, by half an hour's action of conc. nitric acid on the normal nitrate. The brownish powder is very unstable. He also prepared **cobaltic peroxo-decamminohydrochloronitrate**, $[\text{Co}_2(\text{O}_2)(\text{NH}_3)_{10}](\text{NO}_3)_2 \cdot \text{Cl}_2 \cdot 4\text{HCl} \cdot \text{H}_2\text{O}$, by the action of conc. hydrochloric acid on the nitrate. The brownish-violet crystals are very unstable. By the action of nitric acid on the sulphate, G. Vortmann also prepared **cobaltic peroxo-decamminohydrosulphatonitrate**, $[\text{Co}_2(\text{O}_2)(\text{NH}_3)_{10}](\text{SO}_4)(\text{NO}_3)_2 \cdot 4\text{HNO}_3 \cdot \text{H}_2\text{O}$, in brownish-violet, unstable crystals.

G. Vortmann prepared what was formerly called *anhydroxycobaltamminenitrate*, or **cobaltic peroxo-decamminopentanitrate**, $[(\text{NH}_3)_5\text{Co}-\text{O}_2-\text{Co}(\text{NH}_3)_5](\text{NO}_3)_5$, by dissolving the tetranitrate, just described, in warm nitric acid (1 : 1), and cooling, and re-crystallizing from water acidulated with nitric acid. A. Werner and A. Mylius recommended the following process:

Fifty grms. of cobalt carbonate, dissolved in the necessary quantity of dil. nitric acid, are mixed with 200 grms. of ammonium nitrate, and filtered, mixed with 600 c.c. of ammonia (20 per cent.), and treated with a current of air for 26 to 48 hours, until the soln. no longer smells strongly of ammonia. The black soln., which contains crystals of E. Frémy's tetranitrate, is evaporated to a magma in a current of air, mixed with nitric acid, and the salt separated by filtration, and washed with cold, dil. nitric acid until the filtrate is

colourless. The pentanitrate is completely insoluble in dil. nitric acid, whereas it is quickly decomposed by pure water. It crystallizes from hot, dil. nitric acid (20 c.c. acid to 1000 c.c. water) in black, lustrous needles.

S. M. Jörgensen used a similar process. G. Vortmann observed that the salt decomposes with the evolution of oxygen. A. Werner and A. Mylius found that when treated with hydrochloric acid, the salt forms chloropentamminochloride; sulphurous acid converts it into aquopentamminonitrate; and potassium cyanide forms a complex cyanide with the evolution of ammonia and hydrogen cyanide. G. Vortmann observed that if the corresponding chloride is treated with dil. hydrochloric acid, **cobaltic peroxo-decamminochlorotetranitrate**, $[\text{Co}_2(\text{O}_2)(\text{NH}_3)_{10}]\text{Cl}(\text{NO}_3)_4 \cdot \text{H}_2\text{O}$, in leek-green crystals is formed; and with conc. hydrochloric acid, **cobaltic peroxo-decamminotrichlorodinitrate**, $[\text{Co}_2(\text{O}_2)(\text{NH}_3)_{10}]\text{Cl}_3(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$, is formed, also in leek-green crystals. When peroxo-decamminotetranitrate is treated with sulphuric acid (1:1), and cooled, **cobaltic peroxo-decamminonitratodisulphate**, $[\text{Co}_2(\text{O}_2)(\text{NH}_3)_{10}](\text{SO}_4)_2\text{NO}_3 \cdot \text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$, is formed in green crystals, which are sparingly soluble in water, and become matte at 110° . A. Werner prepared **cobaltic trichlorohydroxy-peroxohexamminonitrate**, $[\text{Cl}_2(\text{NH}_3)_3-\text{O}_2-\text{Co}(\text{NH}_3)_3(\text{OH})\text{Cl}]\text{NO}_3$, by treating the corresponding chloride with conc. nitric acid.

A. Werner and co-workers prepared what they called **cobaltic diozotriimidodecamminonitrate**, $[\text{Co}_4(\text{O}_2)_2(\text{NH}_3)_3(\text{NH}_3)_{10}](\text{NO}_3)_5 \cdot 5\text{H}_2\text{O}$, by treating a soln. of the chloride in dil. nitric acid with silver nitrate. The product furnishes black, tetrahedral crystals. When treated with warm, conc. nitric acid, it yields cobaltous salts and a bright red salt which, when treated with hydrochloric acid, is converted into the dichloroaquotriamminochloride. When treated with nitrous acid, it yields an imidohexammine salt, probably nitratotriaquaimido hexamminonitrate, and the mother-liquors of this salt, when treated with hydrochloric acid, yield the dichlorotetramminochloride and a dark-coloured salt of unknown composition.

A. Werner and co-workers obtained **cobaltic sulphatoimino-octamminonitrate**, $[(\text{NH}_3)_4\text{Co}=(\text{NH})(\text{SO}_4)=\text{Co}(\text{NH}_3)_4](\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$, in pale violet crystals, by treating sulphato- μ -amino-octamminonitrate with conc. ammonia. A. Werner prepared **cobaltic μ -aminodecamminonitrate**, $[(\text{NH}_3)_5\text{Co}-\text{NH}_2 \cdots \text{Co}(\text{NH}_3)_5](\text{NO}_3)_5$, when μ -amino-ol-octamminonitrate is treated with cold, conc. nitric acid. As indicated below, it forms nitratoaquo- μ -amino-octamminonitrate, and this is converted into μ -amino-decamminonitrate when it is gradually added to well-stirred, liquid ammonia—a small quantity of the initial salt is at the same time regenerated. The same compound is produced by treating chloroaquo- μ -amino-octamminochloride with conc. nitric acid, and dissolving the product of the reaction, chloronitratato- μ -amino-octamminonitrate, in liquid ammonia, and, after evaporating off the ammonia, the residue is covered with water, and heated on a water-bath until the greater part has dissolved. The insoluble part is filtered from the hot soln., and re-crystallized from water containing acetic acid, when long, red needles of the μ -amino-decamminonitrate are formed. The constitution of this salt was determined independently of the octammine series, as chloropentammine and hexammine salts are obtained by the action of a mixture of hydrochloric and sulphuric acids, from which the deduction is made that 5 mols. of ammonia are attached to each of the cobalt atoms, thus: $[(\text{NH}_3)_5\text{Co} \cdot \text{NH}_2 \cdot \text{Co}(\text{NH}_3)_5]\text{Cl}_5 + \text{HCl} = [\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2 + [\text{Co}(\text{NH}_3)_6]\text{Cl}_3$. That the decammine salt is not an imino-derivative of the type, $[(\text{NH}_3)_5\text{Co} \cdot \text{NH}(\text{HCl}) \cdot \text{Co}(\text{NH}_3)_5]\text{Cl}_4$, is shown by its behaviour towards alkalis, the elements of hydrogen chloride not being withdrawn. The bluish-red needles are soluble in 200 grms. of water per gram of salt, and the soln. has a neutral reaction; it is precipitated almost quantitatively from its aq. soln. by nitric acid; and it is not decomposed by boiling nitric acid. A. Werner and A. Baselli prepared **cobaltic nitratato-aquo- μ -amino-octamminonitrate**, $[(\text{H}_2\text{O})(\text{NH}_3)_4\text{Co} \cdots \text{NH}_2-\text{Co}(\text{NH}_3)_4(\text{NO}_3)](\text{NO}_3)_4$, by triturating 5 grms. of μ -amino-ol-octamminonitrate with 15 c.c. of cold, conc. nitric acid, allowing the mixture to stand for 12 hrs., draining the crystals on a porous plate, and washing several times with

alcohol. The violet powder is converted by liquid ammonia into the μ -amino-decamminonitrate. The aq. soln. reacts acidic, since, by aquation, $[\text{Co}_2(\text{NH}_2)(\text{NH}_3)_8(\text{H}_2\text{O})](\text{NO}_3)_5$, is formed. A. Werner prepared **cobaltic chloronitrato- μ -amino-octamminonitrate**, $[\text{Cl}(\text{NH}_3)_4\text{Co}-\text{NH}_2\cdots\text{Co}(\text{NH}_3)_4(\text{NO}_3)](\text{NO}_3)_3$, by treating a freshly-prepared soln. of chloroaquo- μ -amino-octamminochloride with conc. nitric acid. The greyish-violet needles readily dissolve in water; the freshly-prepared soln. gives no precipitate with silver nitrate, but when the soln. has aged for a few hours, it gives a precipitate of silver chloride, indicating that some aquation has taken place. Dil. sulphuric acid precipitates μ -amino-octamminosulphate from the warm soln. of the nitrate. A. Werner, and I. Fürstenberg prepared **cobaltic tetrabromo- μ -amino-hexamminonitrate**, $[\text{Br}_2(\text{NH}_3)_3\text{Co}-\text{NH}_2\cdots\text{Co}(\text{NH}_3)_3\text{Br}_2]\text{NO}_3 \cdot 2\text{H}_2\text{O}$, by treating the bromide with nitric acid (1:1). The brownish-green powder loses 2 mols. of water at 80° . A. Werner obtained **cobaltic trichloronitrato- μ -amino-hexamminonitrate**, $[\text{Cl}_2(\text{NH}_3)_3\text{Co}-\text{NH}_2\cdots\text{Co}(\text{NH}_3)_3(\text{NO}_3)\text{Cl}]\text{NO}_3$, in violet-black crystals, by the action of conc. nitric acid on trichloroaquo- μ -amino-hexamminochloride, and precipitating the salt from the cold, aq. soln. by conc. nitric acid.

According to A. Werner and A. Baselli, **cobaltic sulphato- μ -amino-octamminonitrate**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{SO}_4)\cdots\text{Co}(\text{NH}_3)_4](\text{NO}_3)_3$, can be obtained by treating cobalt with fuming nitric acid, and, after allowing the mixture to remain for an hour, washing the violet precipitate with water, this operation being repeated three times; the precipitate is then washed with water until the wash-water becomes violet-red, and the product re-crystallized from dilute nitric acid; it cannot, however, be completely purified by this means. In order to obtain the pure salt, the crude product is converted into the chloronitrate, dissolved in the smallest quantity of water, and precipitated with nitric acid; it crystallizes in small, violet leaflets, is only sparingly soluble in cold water, and decomposes when heated on the water-bath, especially in the absence of free acid; but the dry salt is stable at 110° . The sulphuric acid contained in this salt cannot be detected by a direct method. A. Werner and A. Baselli also prepared **cobaltic sulphato- μ -amino-octamminodichloronitrate**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{SO}_4)\cdots\text{Co}(\text{NH}_3)_4](\text{NO}_3)\text{Cl}_2$, by dissolving the crude nitrate in hydrochloric acid on the water-bath, filtering as quickly as possible, and cooling the filtrate with ice and salt, the crystalline product being washed free from acid with water and with alcohol, and dried on a porous plate over sulphuric acid. It crystallizes in slender, microscopic, violet needles, easily soluble in water, and when warmed with hydrochloric acid and water, is converted into the sulphato- μ -amino-octammine salt. The aq. soln. gives characteristic precipitates with several metallic salts; for example, the sat., aq. soln. gives precipitates with sodium and potassium iodides and bromides, with potassium ferrocyanide and ferricyanide, with auric chloride, with hydrochloroplatinic acid, and with oxalic acid. A. Werner prepared optically inactive or racemic **cobaltic sulphato- μ -amino-quaterethylenediaminenitrate**, $[\text{en}_2\text{Co}=(\text{NH}_2)(\text{SO}_4)\cdots\text{Co en}_2](\text{NO}_3)_3 \cdot 2\text{H}_2\text{O}$, in red prisms, from the μ -amino-peroxo-quaterethylenediaminenitrate, by dissolution in conc. sulphuric acid; this is attended by the development of heat, and, on cooling, reddish-brown crystals separate. Further treatment with sulphur dioxide gives a red salt, from the aq. soln. of which concentrated nitric acid precipitates the required nitrate as light red needles. The optically active *dextro*-salt is obtained by treating *laevo*- μ -amino-peroxo-quaterethylenediaminenitrate with sulphurous acid, as just indicated for the optically inactive salt. The sp. rotation of a 0.125 per cent. aq. soln. is $[\alpha]=200^\circ$.

A. Werner prepared **cobaltic diol-octamminonitrate**, $[(\text{NH}_3)_4\text{Co}\cdots(\text{OH})_2\cdots\text{Co}(\text{NH}_3)_4](\text{NO}_3)_4$, as a bright carmine-red crystalline powder, by adding 25 c.c. of a cold, sat. soln. of sodium nitrate to a soln. of 3 grms. of the corresponding chloride in 140 c.c. of water, and reprecipitating the salt by sodium nitrate from its aq. soln. A. Werner and J. Rapiort obtained **cobaltic diol-quaterethylenediaminenitrate**, $[\text{en}_2\text{Co}\cdots(\text{OH})_2\cdots\text{Co en}_2](\text{NO}_3)_4$, by similarly treating an aq. soln. of the corre-

spending bromide. The purple, crystalline powder is readily soluble in water. E. Rosenbohm found the magnetic susceptibility to be -0.193×10^{-6} mass unit; and L. C. Jackson studied the magnetic properties of the salt. A. Werner obtained **cobaltic dinitrato-diol-hexamminonitrate**, $[(\text{NO}_3)(\text{NH}_3)_3\text{Co} \cdots (\text{OH})_2 \cdots \text{Co}(\text{NH}_3)_3(\text{NO}_3)](\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$, by treating an ice-cold soln. of triol-hexamminosulphate in 8 c.c. of water, with 5 c.c. of cold nitric acid (1 : 1), and stirring the mixture for 5 to 10 mins. The crystals are drained, washed with alcohol and ether; and purified by adding nitric acid to the aq. soln. The pale violet scales form a bluish-red soln. with water; the aq. soln. reacts neutral, but with ageing, the soln. becomes acidic, owing to aquation.

A. Werner prepared **cobaltic hydroxyaquo-peroxo-ol-hexamminonitrate**, $[(\text{OH})(\text{NH}_3)_3\text{Co}=(\text{OH})(\text{O}_2) \cdots \text{Co}(\text{NH}_3)_3(\text{H}_2\text{O})](\text{NO}_3)_3$, by triturating the corresponding sulphate with ammonium nitrate and water acidulated with acetic acid, precipitating from the filtrate with ammonium nitrate, and purifying by adding alcohol to the aq. soln. It is also present amongst the products obtained by treating cobalt melanochloride with silver nitrate. The dark brown, tabular crystals form, with water, a brown soln. having an alkaline reaction. If a cold, aq. soln., acidified with acetic acid, be treated with conc. hydrochloric acid, the chloride of the series is not obtained, for the ol-bridge is broken, and trichlorohydroxy-peroxo-hexamminochloride is formed—*vide supra*.

A. Werner obtained **cobaltic μ -imino-peroxo-quaterethylenediaminenitrate**, $[\text{en}_2\text{Co}=(\text{O}_2)(\text{NH})=\text{Co en}_2](\text{NO}_3)_3$, in brown needles, by triturating the iodide with water and the theoretical amount of silver nitrate, and evaporating the filtrate over sulphuric acid. The aq. soln. gives a precipitate of silver nitrate. The addition compound, **silver cobaltic μ -imino-peroxo-quaterethylenediaminenitrate**, $3[\text{Co}_2(\text{O}_2)(\text{NH})\text{en}_4](\text{NO}_3)_3 \cdot 5\text{AgNO}_3$, was obtained in dark brown crystals; and similarly, copper nitrate furnishes **copper cobaltic μ -imino-peroxo-quaterethylenediaminenitrate**, in apple-green crystals; and mercuric chloride gives bright red crystals of **mercuric cobaltic μ -imino-peroxo-quaterethylenediamine-chloronitrate**.

A. Werner obtained **cobaltic μ -amino-peroxo-quaterethylenediaminenitrate**, $[\text{en}_2\text{Co}=(\text{O}_2)(\text{NH}.\text{HNO})=\text{Co en}_2](\text{NO}_3)_3 \cdot 2\text{H}_2\text{O}$, by triturating μ -amino-peroxo-octamminonitrate with 10 per cent. ethylenediamine, and boiling the mixture until ammonia is no longer given off. The cold, brown liquor is mixed with nitric acid, added drop by drop, until the colour becomes red, and it is then cooled in a freezing mixture. The red, crystalline powder is washed with alcohol and ether. The salt in soln. changes into the green isomeric μ -amino-peroxo-quaterethylenediaminenitrate.

A. Werner and F. Beddow, and C. Schwenk prepared **cobaltic μ -amino-peroxo-octamminonitrate**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{O}_2) \cdots \text{Co}(\text{NH}_3)_4](\text{NO}_3)_4$, which they regarded as a *dihydrate*, by treating cobalt fuscousulphate with conc. nitric acid; on diluting with water, a dark green soln. is obtained, and a violet-red, insoluble salt; on mixing the aq. soln. with conc. nitric acid, the nitrate is precipitated. It crystallizes from acidified water in dark green prisms; it is very soluble in water; and it decomposes in neutral solns. with the evolution of ammonia and the precipitation of cobalt oxide; when heated at 100° , it does not give off its water of crystallization. They also said that a *hexahydrate* can be obtained by precipitating a well-cooled soln. of the preceding salt with a small quantity of nitric acid; and it crystallizes in silky, olive-green needles. When this nitrate is heated with an aq. soln. of ammonium carbonate, a dark brown salt is deposited, which has the composition of a basic tetrammine salt. It is sparingly soluble in cold water, easily so in warm water acidified with acetic acid, and crystallizes in black, flat prisms: a salt which is probably identical with this is obtained on treating the nitrate with ammonia. Neither A. Werner and A. Baselli, nor A. Werner and A. Grün could prepare these hydrates; the anhydrous salt was always obtained. The peroxo-salt is reduced by potassium iodide, or by sulphurous or nitrous acids. The central group is so stable that when this nitrate is warmed with 10 per cent. ethylenediamine, all the NH_3 -groups can be displaced to furnish **cobaltic μ -amino-peroxo-quaterethylenediaminenitrate**, $[\text{en}_2\text{Co}=(\text{NH}_2)(\text{O}_2) \cdots \text{Co en}_2](\text{NO}_3)_4$, in green needles. According to A. Werner and co-workers, if a well-cooled soln. of the optically-

active camphorbromosulphonates of the series be treated with conc. nitric acid and then with alcohol, the *dextro-salt*, and the *laevo-salt* can be obtained as pale olive-green, crystalline powders, very soluble in water. The sp. rotations of 0.125 per cent. aq. soln. are $[\alpha] = \pm 920^\circ$.

A. Werner prepared symmetrical—*vide supra*, the corresponding chlorides—**cobaltic dichloro- μ -amino-peroxo-hexamminonitrate**, $[\text{Cl}(\text{NH}_3)_3\text{Co}=(\text{NH}_2)(\text{O}_2)\cdots\text{Co}(\text{NH}_3)_3\text{Cl}](\text{NO}_3)_2$, by triturating the chloride several times with conc. nitric acid. The black, microcrystalline powder is sparingly soluble in water.

A. Werner obtained **cobaltic μ -amino-ol-octamminonitrate**, $[(\text{NH}_3)_4\text{Co}=(\text{NH}_2)(\text{OH})\cdots\text{Co}(\text{NH}_3)_4](\text{NO}_3)_4$, by acting on the corresponding chloride with silver nitrate, and precipitating from the filtered soln. with nitric acid. The raspberry-red prisms, needles, or scales are stable at 80° ; 100 grms. of water dissolve 0.833 grm. of the salt at room temp., but the neutral soln. is unstable. Conc. hydrochloric acid forms chloroaquo- μ -amino-octamminochloride; and triturating with ammonium bromide furnishes the bromide.

A. Werner and co-workers—I. Fürstenberg, F. Steinitzer, and A. Mylius—prepared **cobaltic diaquo- μ -amino-ol-hexamminonitrate**, $[(\text{H}_2\text{O})(\text{NH}_3)_3\text{Co}\cdots(\text{NH}_2)(\text{OH})\cdots(\text{NH}_3)_3(\text{H}_2\text{O})](\text{NO}_3)_4 \cdot 2\text{H}_2\text{O}$. A mixture of 650 grms. of cobalt chloride with 400 c.c. of water and 2 litres of 25 per cent. ammonia is heated to boiling, filtered from the precipitated cobalt oxide, and exposed to the air for 48 hrs. The resulting brownish-red solution is filtered from the crystals which have deposited, and mixed with 3 litres of concentrated hydrochloric acid. The resulting brownish-red precipitate is quickly collected and extracted with cold water until it becomes pure grey in colour and the wash-water is coloured a brownish-violet. One kilogram of cobalt chloride gives about 60 grms. of melano-chloride. The aq. soln. is acidic, owing to the hydration represented as a balanced reaction by the equation:

so that both the ol- and the diol-salts are precipitated from aq. soln. Potassium bromide or iodide gives the corresponding salts of μ -amino-diol-hexammine; warm hydrochloric acid gives trichloro-aquo- μ -amino-hexamminochloride; warm hydrobromic acid forms tetrabromo- μ -amino-hexamminobromide; and warm acetic acid forms the μ -amino-ol-acetatohexammine. The salt is precipitated from a cold, aq. soln. by conc. nitric acid, or ammonium nitrate; and, according to A. Werner and co-workers, hot, conc. nitric acid yields **cobaltic nitratoaquo- μ -amino-ol-hexamminonitrate**, $[(\text{H}_2\text{O})(\text{NH}_3)_3\text{Co}\cdots(\text{NH}_2)(\text{OH})\cdots\text{Co}(\text{NH}_3)_3(\text{NO}_3)](\text{NO}_3)_3 \cdot 2\text{H}_2\text{O}$. This salt was prepared by A. Werner, by dissolving a gram of diaquo- μ -amino-ol-hexamminonitrate in 7 c.c. of hot water to which a few drops of nitric acid have been added, 18 c.c. of conc. nitric acid are added to the well-cooled soln., and in a few minutes, yellowish-brown, flat needles separate out. The salt can be re-crystallized from warm water by the addition of nitric acid. Liquid ammonia converts it into μ -amino-ol-octamminonitrate.

A. Werner prepared **cobaltic triol-hexamminonitrate**, $[(\text{NH}_3)_3\text{Co}\cdots(\text{OH})_3\cdots\text{Co}(\text{NH}_3)_3](\text{NO}_3)_3 \cdot 2\text{H}_2\text{O}$, by treating an ice-cold, conc., aq. soln. of the chloride or bromide with sodium nitrate, and re-crystallizing from a little water by adding sodium nitrate. The red prisms of the *dihydrate* lost the water of hydration over sulphuric acid, phosphorus pentoxide, or at 60° ; 100 grms. of water dissolve 8.33 grm. of the salt at room temp.

According to A. Pieroni and A. Pinotti, red, acicular crystals are precipitated when nitric acid is added to a soln. of diol-peroxo-sexiesallylaminechloride, and W. R. Bucknall and W. Wardlaw found that **cobaltic diol-peroxo-sexiesallylaminonitrate**, $[(\text{C}_3\text{H}_5\text{NH}_2)_3\text{Co}\cdots(\text{O}_2)(\text{OH})\cdots\text{Co}(\text{C}_3\text{H}_5\text{NH}_2)_3](\text{NO}_3)$, can be prepared by the addition of about 1 c.c. of nitric acid to 20 c.c. of a soln. of the complex

chloride (2 grms.), and freed from acid by washing with cold water, in which it is slightly soluble; the filtered substance can be air-dried on a porous plate. It contained no chlorine, and when it was moistened with sulphuric acid, nitric acid was liberated. It was slightly soluble in cold water, and on standing, or by warming, hydrolysis occurred, with the precipitation of hydroxide. Warming with sodium hydroxide caused the evolution of allylamine, and by distillation with sodium hydroxide and Devarda's alloy, the nitrate groups are reduced to ammonia. The nitrate is hydrolyzed by boiling water, but the presence of nitric acid retards the hydrolysis; if the conc. of the nitric acid is too great, the salt is dissolved and the complex ion broken down.

According to A. Werner, **cobaltic μ -amino-diol-hexamminonitrate**, $[(\text{NH}_3)_3\text{Co} \cdots (\text{NH}_2)(\text{OH})_2 \cdots \text{Co}(\text{NH}_3)_3](\text{NO}_3)_3 \cdot 2\text{H}_2\text{O}$, is formed by the action of a conc. soln. of silver nitrate on the corresponding iodide, and the subsequent addition of alcohol. The red crystals furnish an aq. soln. with a neutral reaction. A. Werner and co-workers—A. Baselli, F. Steinitzer and K. Rücker, and F. M. Grigorieff—obtained **cobaltic μ -amino-ol-peroxo-hexamminonitrate**, $[(\text{NH}_3)_3\text{Co} \cdots (\text{NH}_2)_2(\text{OH})(\text{O}_2) \cdots \text{Co}(\text{NH}_3)_3](\text{NO}_3)_3 \cdot \text{H}_2\text{O}$, as a by-product in the action of silver nitrate on the melanochloride. It is also produced when the corresponding bromide is treated with the theoretical quantity of silver nitrate in cold soln., and the filtrate treated with alcohol. The green scales form a greenish-brown soln., which becomes red when reduced with sulphurous acid; hydrochloric and hydrobromic acids break down the ol-bridge to form the dichlorochloride, or dibromo-bromide; and fuming nitric acid forms trinitratotriammine.

S. M. Jørgensen observed that **cobaltic hexol-dodecamminonitrate**, $[\text{Co}\{(\text{OH})_2=\text{Co}(\text{NH}_3)_4\}_3](\text{NO}_3)_6$, is precipitated, in greyish-brown, acicular crystals when a soln. of the corresponding chloride is treated with dil. nitric acid, and the product washed with alcohol and ether, and dried over sulphuric acid. The aq. soln. has a neutral reaction, and behaves towards general reagents like a soln. of the chloride. A. Werner found that **cobaltic hexol-sexiesethylenediaminenitrate**, $[\text{Co}\{(\text{OH})_2=\text{Co}(\text{en})_2\}_3](\text{NO}_3)_6 \cdot 3\text{H}_2\text{O}$, is formed when a soln. of cobalt nitrate and of ethylenediamine is submitted to atmospheric oxidation; it crystallizes in long, dark brown needles, yields cis-diaquobisethylenediaminecobaltic halide by solution in conc. hydrochloric or hydrobromic acid, trans-dichlorodietthylenediaminechloride by evaporation with dil. hydrochloric acid, and cis-hydroxo-aquobisethylenediaminenitrate by treatment with potassium hydroxide. The 10 per cent. aq. soln. gives crystalline precipitates with potassium bromide, iodide, and thiocyanate, with sodium nitrate, and with platinic chloride; and no precipitate with sodium nitrite, sulphate, and dithionate, or with ammonium chloride. E. Schmidt obtained this salt. The complex with gum arabic was studied by H. G. B. de Jong and J. Lens.

§ 29. Cobaltous Phosphates

According to H. Rose,¹ A. Salvétat, W. J. Russell, and A. Terreil, when a soln. of a cobaltous salt is treated with sodium hydrophosphate, reddish-violet flakes are formed, and when heated in hydrogen gas, it furnishes cobalt tritadiphosphide, so that the salt probably contains the molar proportion $\text{CoO} : \text{P}_2\text{O}_5 = 3 : 1$, that is, **cobaltous orthophosphate**, $\text{Co}_3(\text{PO}_4)_2$. A. Reynoso obtained small, octahedral, rose-red crystals by heating the pyrophosphate with water, in a sealed tube, for 5 or 6 hrs. at 280° to 300° ; and F. Ephraim and C. Rossetti obtained rectangular plates by crystallization from a soln. containing more than a mol. of P_2O_5 to 3 mols. of CoO . E. Birk and W. Biltz observed that the dehydrated phosphate has the sp. gr. 2.587 at $25^\circ/4^\circ$, and the mol. vol. 141.8. F. de Boer studied the K-series of the X-ray absorption spectrum; and E. F. Herroun, its magnetic properties. The violet-salt forms a deep red soln. with an excess of phosphoric acid; it dissolves in aq. ammonia, and in a soln. of ammonium chloride or nitrate. A. Salvétat observed that the reddish-violet salt becomes violet-blue when heated; and J. B. Senderens noted that it is not attacked by sulphur in boiling water. E. Birk and W. Biltz observed that the dehydrated salt is not attacked by ammonia under press.; A. Naumann, that it is insoluble

in methyl acetate; and J. A. Hedvall and J. Heuberger studied the reactions with heated alkaline earth oxides. According to H. Debray, the *dihydrate*, $\text{Co}_3(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$, is formed when hydrated cobaltous hydrophosphate is heated with water, or with cobaltous nitrate, in a sealed tube, at 250° ; or, according to G. Chancel, when hydrated ammonium cobaltous phosphate is boiled with water. H. Bassett and W. L. Bedwell obtained the *tetrahydrate*, $\text{Co}_3(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$. A. Reynoso obtained the *octohydrate*, $\text{Co}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$, by adding alcohol to a soln. of the dihydrophosphate; H. Bassett and W. L. Bedwell also prepared this salt. According to M. Reitler, the commercial salt is the octohydrate. E. Birk and W. Biltz observed that if the flocculent precipitate of cobalt orthophosphate is allowed to stand in the mother-liquor, it forms the crystalline octohydrate. The sp. gr. is 2.769 at $25^\circ/4^\circ$; and the mol. vol., 184.6 . The hydrate loses all its combined water at 200° . N. S. Kurnakoff and I. A. Andreevsky found that the dehydration curves have breaks at 110° , 190° , and 270° . According to E. Birk and W. Biltz, the hydrate is easily soluble in conc. aq. ammonia. R. F. Weinland and co-workers obtained a complex salt with pyridine, namely, $\text{Co}_3(\text{PO}_4)_2 \cdot \text{C}_5\text{H}_5\text{N} \cdot 6\text{H}_2\text{O}$, as a violet-blue powder. J. A. Hedvall and E. Norström studied the reactions with the oxides of the alkaline earths. W. Muthmann and H. Heramhof tried cobalt phosphate as a pigment for porcelain.

H. Debray obtained **ammonium cobaltous orthophosphate**, $(\text{NH}_4)\text{CoPO}_4 \cdot 6\text{H}_2\text{O}$, or $(\text{NH}_4)_3\text{PO}_4 \cdot \text{Co}_3(\text{PO}_4)_2 \cdot 18\text{H}_2\text{O}$, as a *hexahydrate*, by the action of an excess of ammonium phosphate on a soln. of a cobalt salt at 80° ; M. Porumbaru, by heating neutral or acid cobaltic aquopentamminopyrophosphate, in a sealed tube, at 225° ; and H. D. Dakin obtained the *monohydrate*, by evaporating to dryness, at 100° to 105° , a soln., of a cobalt salt mixed with ammonium hydrophosphate. The monohydrate furnishes violet crystals which do not decompose in boiling water, and which do not lose ammonia at 110° . The subject was discussed by A. Brand, P. Dirvell, H. Bassett and W. L. Bedwell, H. Behrens, and O. Richter. G. Chancel also described rose-red crystals of the *dodecahydrate* obtained by treating a cold soln. of a cobalt salt with an excess of ammonium phosphate, and allowing the bluish-violet, gelatinous precipitate to stand in contact with its mother-liquor for some time. The crystals partially decompose at 100° into cobaltous and ammonium phosphates.

L. Ouvrard melted cobalt oxide with potassium pyrophosphate or hydrophosphate, potassium metaphosphate or orthophosphate with an excess of cobalt oxide, or cobaltous orthophosphate and potassium chloride, and obtained **potassium cobaltous orthophosphate**, KCoPO_4 , or $\text{K}_3\text{PO}_4 \cdot \text{Co}_3(\text{PO}_4)_2$, and H. Grandeau obtained the same salt by heating cobaltous orthophosphate with potassium sulphate between 800° and 1000° , and washing the product with water. The blue, rhombic crystals have the sp. gr. 3.5 at 20° , and are easily soluble in acids. If the temp. of preparation is in the vicinity of 1400° , some higher oxide of cobalt is formed. L. Ouvrard melted potassium metaphosphate with cobalt oxide and obtained rose-red, monoclinic crystals of potassium cobaltous phosphate, $\text{K}_3\text{PO}_4 \cdot 3\text{KCoPO}_4$, or $2\text{K}_3\text{PO}_4 \cdot \text{Co}_3(\text{PO}_4)_2$, of sp. gr. 2.9 at 20° . The presence of potassium chloride favours crystallization. The crystals are soluble in acids. L. Ouvrard also obtained **sodium cobaltous orthophosphate** by fusing together sodium metaphosphate with an excess of cobalt oxide in the presence of sodium chloride; and also by fusing sodium pyrophosphate with an excess of cobalt oxide; or cobaltous orthophosphate with an excess of sodium chloride. The rhombic prisms are isomorphous with those of the corresponding zinc salt, and have a sp. gr. 3.6 at 20° . By melting together sodium pyrophosphate with a small proportion of cobalt oxide; or sodium orthophosphate and cobalt oxide, crystals of $\text{Na}_3\text{PO}_4 \cdot \text{NaCoPO}_4$, or $\text{Na}_4\text{Co}(\text{PO}_4)_2$, isomorphous with those of the corresponding zinc salt, are obtained. Their sp. gr. is 2.5 at 20° .

J. G. Gentile obtained **zinc cobaltous orthophosphate**, $3\text{Zn}_3(\text{PO}_4)_2 \cdot \text{Co}_3(\text{PO}_4)_2 \cdot 12\text{H}_2\text{O}$, by adding a mixed soln. of zinc and cobalt sulphates to an excess of a

soln. of sodium hydrophosphate, the green precipitate which soon becomes blue. An excess of zinc sulphate yields a green precipitate, and an excess of cobalt sulphate, a blue one. J. G. Gentile described the use of the mixed salt as a pottery colour. A. G. Bergman prepared **uranyl cobaltous phosphate**, $\text{Co}(\text{UO}_2)_2(\text{PO}_4)_2$.

According to H. Debray,² **cobaltous hydrophosphate**, $\text{CoHPO}_4 \cdot 1\frac{1}{2}\text{H}_2\text{O}$, is formed by digesting cobaltous carbonate with phosphoric acid, and boiling the acidic soln.; and the same *hemitriphosphate*, $\text{CoHPO}_4 \cdot 1\frac{1}{2}\text{H}_2\text{O}$, also by boiling a soln. of cobaltous dihydrophosphate with a cobaltous salt. F. Ephraim and C. Rossetti observed that the hydrated hydrophosphate, $\text{CoHPO}_4 \cdot n\text{H}_2\text{O}$, is a well-defined, crystalline compound. C. H. D. Bödeker prepared the *hemipentahydrate*, $\text{CoHPO}_4 \cdot 2\frac{1}{2}\text{H}_2\text{O}$, in pale violet-red crystals, by adding an excess of sodium hydrophosphate to a soln. of cobaltous chloride, dissolving half the lilac-red precipitate in the smallest possible quantity of hydrochloric acid, digesting the other half with the soln. so obtained, and allowing the liquid to stand for some time. H. Bassett and W. L. Bedwell studied the constitution of the salt. R. F. Weinland and co-workers obtained a complex salt with pyridine, viz., $2\text{CoHPO}_4 \cdot 7\text{C}_5\text{H}_5\text{N} \cdot 8\text{H}_2\text{O}$, as a rose-red, crystalline powder.

H. Debray prepared **sodium cobaltous hydrophosphate**, $\text{Co}_3(\text{PO}_4)_2 \cdot 2\text{Na}_2\text{HPO}_4 \cdot 8\text{H}_2\text{O}$, by adding an excess of sodium hydrophosphate to a soln. of a cobaltous salt, digesting the gelatinous precipitate with an excess of a soln. of sodium hydrophosphate at 80° for 15 to 20 days; the blue liquid which is formed deposits the salt in blue, tabular crystals. This salt was also prepared by H. Bassett and W. L. Bedwell.

A. Reynoso³ heated cobaltous pyrophosphate with water, in a sealed tube, at 280° for 5 to 6 hrs.; cobaltous orthophosphate is precipitated in rose-red, octahedral crystals, and **cobaltous dihydrophosphate**, $\text{Co}(\text{H}_2\text{PO}_4)_2$, remains in soln. The evaporation of the soln. yields a gum-like mass of the dihydrophosphate. The aq. soln. is decomposed by alcohol.

H. Debray observed that when precipitated ammonium cobaltous phosphate is digested with a conc. acidic soln. of ammonium phosphate for 7 or 8 days, it forms rose-red, insoluble crystals of **ammonium cobaltous dihydrophosphate**, $(\text{NH}_4)\text{CoPO}_4 \cdot (\text{NH}_4)_2\text{H}_2\text{PO}_4 \cdot 4\text{H}_2\text{O}$.

According to F. Schwarz,⁴ if a soln. of a cobaltous phosphate be treated with sodium triphosphate, **cobaltous triphosphate**, $\text{Co}_m\text{H}_{5-2m}\text{P}_3\text{O}_{10} \cdot n\text{H}_2\text{O}$, is formed as an amorphous precipitate contaminated with a sodium salt. The precipitate quickly re-dissolves. It was also prepared by M. Stange, and P. Glühmann. F. Schwarz mixed a soln. of a gram of octahedral sodium triphosphate, in the least possible quantity of water, with 1.5 to 1.75 grms. of cobalt sulphate. The rose-red precipitate, unwashed, was dried on a porous tile. The analyses of the **sodium cobaltous triphosphate** approximate $\text{NaCo}_2\text{P}_3\text{O}_{10}$, but they varied so much that it might be questioned if a chemical individual is formed under these conditions. A *dodecahydrate* was obtained from soln. of sodium triphosphate and a cobaltous salt in dil. aq. soln. The rose-red crystals become blue when dehydrated, and they fuse to a blue glass; they are easily soluble in acids; and, according to M. Stange, they are isomorphous with those of the corresponding nickel salt.

According to F. Stromeyer,⁵ H. Rose, A. Terreil, and A. Roseheim and co-workers, the precipitate which a soln. of a cobaltous salt furnishes when treated with sodium pyrophosphate, is **cobaltous pyrophosphate**, $\text{Co}_2\text{P}_2\text{O}_7$; it is soluble in an excess of the precipitant, forming a deep green soln. from which it is precipitated when it is allowed to stand for some time. H. D. Dakin obtained it by igniting ammonium cobaltous phosphate. The salt was studied by H. Bassett and W. L. Bedwell. F. W. Clarke found the sp. gr. to be 3.746 at 23° , and 3.710 at 25° . E. F. Herroun, and P. Pascal studied the magnetic properties. A. Reynoso found that when the pyrophosphate is heated, in a sealed tube, with water for some hours at 280° to 300° , it is resolved into acid and normal phosphate. A. Schwarzenberg said that it is insoluble in aq. ammonia. J. A. Hedvall and

H. Heuberger studied the reactions with alkaline earth oxides whereby orthophosphates are formed.

According to C. D. Braun, if cobaltic hexamminometaphosphate be calcined, a smalt-blue powder is formed having the composition $6\text{CoO} \cdot 5\text{P}_2\text{O}_5$; and if cobaltic hexamminohydrophosphate be calcined, the violet powder has the composition $3\text{CoO} \cdot 2\text{P}_2\text{O}_5$.

L. Ouvrard prepared **sodium cobaltous pyrophosphate**, $4\text{Na}_2\text{P}_2\text{O}_7 \cdot 5\text{Co}_2\text{P}_2\text{O}_7$, by fusing a mixture of sodium metaphosphate and cobalt oxide; and K. A. Wallroth, by melting microcosmic salt with cobalt oxide, Co_3O_4 . The salt furnishes dichroic, violet-red prisms isomorphous with the corresponding nickel salt. The sp. gr. is 3.2 at 20° . P. Pascal noted the formation of complexes when freshly-precipitated cobalt pyrophosphate is dissolved in an excess of a soln. of sodium pyrophosphate; and the sp. magnetic susceptibility of the soln. is 3.03×10^{-7} mass unit.

J. H. Gladstone observed that when a feebly ammoniacal soln. of cobalt nitrate is treated with pyrophosphotriaminic acid, violet **cobalt triamidopyrophosphate** is formed.

R. Maddrell⁶ evaporated to dryness a soln. of cobalt sulphate in an excess of phosphoric acid, and heated the residue to 316° . A rose-red powder of **cobaltous monometaphosphate**, $\text{Co}(\text{PO}_3)_2$, is formed, insoluble in water and dil. acids, but soluble in conc. sulphuric acid. A. Glatzel said that the metaphosphate is perceptibly soluble in boiling hydrochloric or nitric acid; it melts at a red-heat, and on cooling it forms a glassy mass. When heated with alkali sulphide soln., cobalt sulphide is precipitated, and alkali metaphosphate remains in soln.

A. Glatzel obtained **cobaltous dimetaphosphate**, $\text{Co}_2(\text{PO}_3)_4$, as a rose-red precipitate on treating a soln. of cobalt chloride with sodium metaphosphate. When heated, the hydrate becomes blue; gives off its water of hydration at a dull red-heat; and then melts, forming, when cold, a glassy mass. P. Hautefeuille and J. Margottet obtained a metaphosphate by melting cobalt oxide with metaphosphoric acid. C. D. Braun obtained the dimetaphosphate by calcining crystals of cobaltic aquopentamminopyrophosphate. The smalt-blue product forms a brown soln. and brown powder when treated with conc., aq. ammonia; potash-lye forms a rose-red powder, and when heated, a blue soln. which gradually oxidizes and deposits hydrated cobaltic oxide. A. Glatzel said that 1 part of the dimetaphosphate dissolves in 25 parts of water; and it dissolves in boiling mineral acids—particularly sulphuric acid. Cold, conc. sulphuric acid does not dissolve the salt, but the hot acid does do so, leaving behind a carmine-red powder which is soluble in water. G. Tammann found that if an excess of a cobalt salt is added to a soln. of sodium dimetaphosphate, **sodium cobaltous dimetaphosphate** is formed.

G. Tammann obtained **cobaltous trimetaphosphate**, $\text{Co}_3(\text{PO}_3)_6 \cdot 9\text{H}_2\text{O}$, by treating sodium trimetaphosphate with cobalt chloride or sulphate. The product is sparingly soluble in water. G. Tammann, and G. Tammann and A. Hollander obtained **disodium tricobaltous trimetaphosphate**, $\text{Na}_2\text{P}_2\text{O}_6 \cdot \text{Co}_3(\text{PO}_3)_6$, as a purple powder consisting of cubic and octahedral crystals, by fusing cobalt sulphate and sodium ammonium hydrophosphate. The salt is insoluble in conc. acids. G. Tammann also treated a soln. of a cobalt salt with one of sodium dimetaphosphate, in equivalent proportions, 3:1, and obtained a precipitate approximating the *henicosihydrate*, $\text{Na}_2\text{P}_2\text{O}_6 \cdot \text{Co}_3(\text{PO}_3)_6 \cdot 21\text{H}_2\text{O}$. R. Maddrell obtained **sodium tricobaltous trimetaphosphate**, $\text{NaPO}_3 \cdot \text{Co}_3(\text{PO}_3)_6$, by evaporating a soln. of phosphoric acid, sodium phosphate, and cobalt sulphate to a syrup, and then heating the product to 316° . The rose-red salt is insoluble in water and dil. acids, but soluble in conc. sulphuric acid. L. Ouvrard reported **tetrasodium cobaltous trimetaphosphate**, $\text{Na}_4\text{Co}(\text{PO}_3)_6$, to be formed by melting a mixture of sodium pyrophosphate and a little cobalt oxide, or sodium orthophosphate and cobalt oxide. The crystals have a sp. gr. 2.5 at 20° , and are isomorphous with those of the corresponding

zinc salt. C. G. Lindbom, and T. Fleitmann and W. Henneberg reported an *octohydrate*, $\text{Na}_4\text{Co}(\text{PO}_3)_6 \cdot 8\text{H}_2\text{O}$, soluble in water. A. Mente prepared **cobalt nitrilotrimetaphosphate**, $\text{CoNP}_3\text{O}_7 \cdot \text{H}_2\text{O}$, by treating a dil. soln. of the acid with cobalt nitrate. The red salt is insoluble in water, slightly soluble in dil. acids, and easily soluble in aq. ammonia. It is decomposed by sodium hydroxide or carbonate, and by ammonium sulphide.

H. Rose observed that sodium hexametaphosphate gives a red precipitate of **cobaltous hexametaphosphate**, $\text{Co}_6(\text{PO}_3)_{12} \cdot n\text{H}_2\text{O}$, when added to a soln. of cobalt chloride, but not the sulphate.

§ 30. Cobaltic Phosphates

G. D. Braun¹ obtained **cobaltic hexamminorthophosphate**, $[\text{Co}(\text{NH}_3)_6]\text{PO}_4 \cdot 4\text{H}_2\text{O}$, by mixing soln. of the hexamminochloride with sodium orthophosphate. The salt was also obtained by O. W. Gibbs, M. Porumbaru, and G. Vortmann. S. M. Jörgensen mixed a warm soln. of 2 grms. of the corresponding nitrate in 200 c.c. of water and 10 to 20 c.c. aq. ammonia, with 3 grms. of normal sodium phosphate in 100 c.c. of water, and washed the precipitate with cold water. The golden-yellow, acicular crystals of the *tetrahydrate*, dried in air, lose their water of hydration at 100° to 130°. W. Biltz observed that when the salt is heated for 3 days at 190° to 200° in a current of carbon dioxide, it furnishes cobaltous pyrophosphate, and the gaseous products—ammonia, water, and nitrogen. E. Birk and W. Biltz gave 1.864 for the sp. gr. of the crystals at 25°/4°; and 137.4 for the mol. vol. P. Mosimann, and F. Ephraim and co-workers observed that a sat., aq. soln. at 18° contains 0.033 grm. or 0.00055 mol of the salt per litre.

R. Klement prepared **cobaltic aquopentamminorthophosphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{PO}_4 \cdot 2\text{H}_2\text{O}$, by the action of normal sodium phosphate on the corresponding nitrate, and he also prepared it from the mother-liquor left in making the phosphatotetrammines. The brownish-red crystals are sparingly soluble in water, and the mol. conductivities of soln. with a mol of the salt in 1000 and 2000 litres of water, are, respectively, 214, and 253. The aq. soln. has an alkaline reaction, and gives an immediate precipitation of silver phosphate when it is treated with silver nitrate; conc. hydrochloric acid converts the salt slowly into the aquopentamminochloride. The basic salt reported by S. M. Jörgensen is considered to be a hydroxypentamminophosphate. J. C. Duff reported **cobaltic orthophosphatopentamminophosphate**, which he represented by the formula :

It is usually formulated as a **cobaltic phosphatopentammine**, $[\text{Co}(\text{NH}_3)_5(\text{PO}_4)] \cdot 2\text{H}_2\text{O}$, in which the pentammine, being associated with a trivalent acid radicle in the nucleus, is nullvalent. A pentammine with a dibasic acid radicle in the complex is univalent; and with a monobasic acid radicle in the complex, bivalent. R. Duval prepared a similar compound. J. C. Duff obtained the phosphatopentammine in brick-red, flattened needles by using as precipitant for aquopentamminonitrate a soln. of 6.73 grms. of hydrated sodium hydrophosphate to which 18.75 c.c. of *N*-NaOH had been added to make the normal phosphate. The salt does not lose water at 100°; it is sparingly soluble in warm water; and gives a precipitate with silver nitrate, but not with ferric chloride. The measurements of the mol. conductivity places the salt in the same class as the carbonato- and similar pentamminosalts, but not with the aquopentammines. The compound was also prepared by C. Duval; but R. Klement could not satisfy himself that the salt is a phosphatopentammine.

R. Klement obtained **cobaltic diaquotetramminorthophosphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]\text{PO}_4$, by mixing warm, equivalent soln. of the diaquo-chloride and normal sodium phosphate. The brick-red crystalline powder is sparingly soluble in water, and the aq. soln. has an alkaline reaction, and it gives a precipitate with silver nitrate. If dichlorodiaquodiamminochloride or dichlorodiaquotriamminochloride be warmed with an aq. soln. of sodium hydrophosphate, a green powder is formed consisting of cobaltous phosphate and **cobaltic phosphatotetrammine**, $[\text{Co}(\text{NH}_3)_4(\text{PO}_4) \cdot n\text{H}_2\text{O}]$, or :

where n may be 2 or 3. The tetrammine is separated by boiling the green powder with a soln. of ammonium phosphate and conc., aq. ammonia, and allowing the violet liquid to cool. The salt can be purified by dissolution in very dil. hydrochloric acid, and precipitation with dil. ammonia. The violet plates very readily lose their water of hydration. The electrical conductivities of soln. with a mol of the salt in 1000 and 2000 litres of water are, respectively, 37 and 65. The salt is sparingly soluble in water; the aq. soln.—0.001 mol per litre—gives no precipitate with silver nitrate; conc. hydrochloric acid forms a mixture of cis- and trans-dichloro-chloride; oxalic acid yields the cis-diaquo-oxalate; and liquid ammonia does not react with the salt. R. Vogel reported **cobaltic chlorobisethylenediaminepyridinephosphate**, and also **cobaltic diphosphatobisethylenediaminephosphate**,

A similar salt, **cobaltic diphosphatobispropylenediaminephosphate**, $[(\text{Co en}_2)_3(\text{PO}_4)_2]\text{PO}_4 \cdot 14\text{H}_2\text{O}$, was prepared by A. Werner and A. Frölich by the action of a soln. of sodium phosphate on the corresponding dichloro-chloride.

C. D. Braun² prepared **cobaltic hexamminohydrophosphate**, $[\text{Co}(\text{NH}_3)_6]_2(\text{HPO}_4)_3 \cdot 4\text{H}_2\text{O}$, by adding a soln. of sodium hydrophosphate to a soln. of a soluble hexammino-salt. The product was probably impure, because his formula very nearly corresponds with $3[\text{Co}(\text{NH}_3)_6]\text{PO}_4 \cdot \text{H}_3\text{PO}_4 \cdot 5\frac{1}{2}\text{H}_2\text{O}$, whereas that prepared by S. M. Jörgensen agrees with that of the tetrahydrate just indicated. S. M. Jörgensen obtained the salt by mixing a soln. of 3 grms. of the hexamminochloride in water acidified with acetic acid with an aq. soln. of 6 grms. of sodium hydrophosphate; and also by neutralizing an aq. soln. of the hexamminocarbonate with 10 per cent. phosphoric acid. The brownish-yellow crystals of the *tetrahydrate* are stable over sulphuric acid, but 3 mols. of water are lost in about a couple of hours at 100°, and the remaining water is given off more slowly. The hydrophosphate is soluble in dil. hydrochloric acid; nitric acid converts it into the hexamminonitrate; and an excess of aq. ammonia converts it into the normal phosphate.

C. and M. Duval prepared **cobaltic phosphatopentamminochloride**, $[\text{Co}(\text{PO}_4)(\text{NH}_3)_5]\text{Cl}$. S. M. Jörgensen reported **cobaltic aquopentamminohydrophosphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_2(\text{HPO}_4)_3 \cdot 4\text{H}_2\text{O}$, to be formed by mixing a soln. of the corresponding carbonate with the theoretical proportion of 10 per cent. phosphoric acid. Oily drops separate from the filtrate, and crystals are formed; then the liquid is allowed to stand in a cool place for a few days. The crystals resemble those the corresponding hexammine. The *tetrahydrate* loses no water over sulphuric acid, but at 100°, it rapidly loses 5 mols. of water, and more is lost slowly at this temp. The salt is sparingly soluble in cold water, and readily soluble in hot water. The undissolved salt melts under hot water, to form a viscid, reddish-brown mass which becomes pale red on cooling.

A. Werner and E. Kindscher prepared **cobaltic diol-octamminohydrophosphate**, $[(\text{NH}_3)_4\text{Co}(\text{OH})_2\text{Co}(\text{NH}_3)_4](\text{HPO}_4)_2 \cdot 6\text{H}_2\text{O}$, by the action of sodium hydrophosphate on the corresponding chloride. The rose-red crystals of the *hexahydrate* are insoluble in water.

J. C. Duff³ reported a **cobaltic phosphatopentamminodihydrophosphate**, which he represented by the formula: $[\text{Co}(\text{NH}_3)_5(\text{HPO}_4)]\text{H}_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$, or rather:

to be formed by adding 5 grms. of the carbonato-nitrate to a soln. of 3 grms. of orthophosphoric acid in 25 c.c. of water at 40°. The salt is said to be very sparingly soluble in cold water, readily soluble in dil. alkali-lye, or dil. mineral

acids. The water of crystallization is lost by the *dihydrate* over sulphuric acid. The salt melts in the steam-oven. R. Duval prepared the complex: $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{PO}_4)](\text{H}_2\text{PO}_4)_2 \cdot 4\text{NH}_4\text{NO}_3$. L. Dede studied the subject.

C. D. Braun,⁴ O. W. Gibbs, G. Vortmann, and M. Porumbaru studied the preparation of **cobaltic hexamminopyrophosphate**, $[\text{Co}(\text{NH}_3)_6]_4(\text{P}_2\text{O}_7)_3 \cdot 20\text{H}_2\text{O}$. S. M. Jörgensen said that when a cold soln. of the hexamminochloride is treated with a soln. of sodium pyrophosphate, the precipitate approximates $[\text{Co}(\text{NH}_3)_6]\text{NaP}_2\text{O}_7 \cdot 11\frac{1}{2}\text{H}_2\text{O}$, and when this is washed with hot water, it is converted into the normal *icosihydrate*. If hot soln. of the component salts are mixed, say at 80° to 85° , **sodium cobaltic hexamminopyrophosphate**, $[\text{Co}(\text{NH}_3)_6]_6(\text{P}_2\text{O}_7)_3(\text{NaP}_2\text{O}_7) \cdot 39\text{H}_2\text{O}$, is formed in yellowish-brown crystals which lose most of their water of hydration when confined over sulphuric acid. The other sodium cobaltic hexamminopyrophosphate retains its composition when washed with cold water, and it furnishes brownish-yellow, six-sided plates, sparingly soluble in water. The salt loses 8 mols. of water over sulphuric acid; and 11 mols. at 100° . This salt was discussed by A. Rosenheim and T. Triantaphyllides. W. Lenz observed no fluorescence with ultra-violet rays.

Returning to the normal icosihydrated hexamminopyrophosphate, S. M. Jörgensen prepared it by treating a cold soln. of the hexamminonitrate with potassium pyrophosphate; or as indicated above. The brownish-yellow, six-sided crystals lose 15 mols. of water very slowly over sulphuric acid, and the salt decomposes at 100° . The salt is almost insoluble in hot and cold water. S. M. Jörgensen said that an acid pyrophosphate, **cobaltic hexamminohydropyrophosphate**, $[\text{Co}(\text{NH}_3)_6]\text{HP}_2\text{O}_7$, is produced when the precipitation is made in soln. acidified with acetic acid. The dark orange-yellow, prismatic crystals are almost insoluble in water, and they are stable in boiling water; soluble in dil. hydrochloric acid; and are converted by dil. soda-lye into the sodium cobaltic salt. The acid salt was discussed by A. Rosenheim and T. Triantaphyllides. W. Lenz observed no fluorescence in ultra-violet light.

M. Porumbaru reported that when the double salt with sodium precipitated on adding an excess of sodium pyrophosphate to a soln. of chloropentamminochloride, is washed with luke-warm water, **cobaltic aquopentamminopyrophosphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]_4(\text{P}_2\text{O}_7)_3 \cdot 12\text{H}_2\text{O}$, is formed. S. M. Jörgensen obtained it by adding the theoretical proportion of sodium pyrophosphate to a soln. of the corresponding sulphate. The red, hexagonal, acicular crystals of the *dodecahydrate* lose 6 mols. of water over sulphuric acid, and 13 mols. of water are lost at 100° . If a soln. of 5 grms. of the aquo-nitrate in 45 c.c. of water and 10 c.c. of 45 per cent. acetic acid, at 80° , is mixed with a soln. of 2 mols. of sodium pyrophosphate in 80 c.c. of water, also at 80° , rectangular prisms of **cobaltic aquopentamminohydropyrophosphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{HP}_2\text{O}_7$, are formed. The salt is insoluble in water, soluble in dil. acetic acid, and freely soluble in dil. hydrochloric acid. If the salt be shaken with dil. soda-lye, it forms **sodium cobaltic aquopentamminopyrophosphate**, $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]\text{NaP}_2\text{O}_7 \cdot 11\frac{1}{2}\text{H}_2\text{O}$. This salt was also described by C. D. Braun, O. W. Gibbs, and, as indicated above, by M. Porumbaru. S. M. Jörgensen obtained it by adding an excess of sodium pyrophosphate to an aq. soln. of the aquo-sulphate. The salt yields hexagonal prisms when re-crystallized from dil. aq. ammonia.

S. M. Jörgensen prepared **cobaltic diaquotetramminopyrophosphate**, $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]_4(\text{P}_2\text{O}_7)_3 \cdot 6\text{H}_2\text{O}$, by adding a 4 per cent. aq. soln. of sodium pyrophosphate to a conc. soln. of the diaquo-sulphate in eq. proportions, and washing the precipitate with water. The *hexahydrate* slowly loses 4 mols. of water over sulphuric acid, and 6 mols. at 100° . The salt is insoluble in water, but easily soluble in dil. acids. If the cold soln. in conc. sulphuric acid is treated with hydrochloric acid, the diaquo-chloride is formed.

C. D. Braun, and O. W. Gibbs obtained **cobaltic chloropentamminopyrophosphate**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{P}_2\text{O}_7 \cdot 4\text{H}_2\text{O}$, by the action of a soln. of sodium pyrophosphate

on a soln. of the chloro-chloride. S. M. Jörgensen recommended shaking soln. of eq. proportions of the chloro-nitrate and sodium pyrophosphate, and shaking the filtrate with alcohol. The violet-red needles lose 3 or 4 mols. of water at 100°. The salt is easily soluble in water, and the soln. has an alkaline reaction. If a very conc., cold, aq. soln. of the chloro-nitrate be treated with a mixture of sodium dihydropyrophosphate with a little free pyrophosphoric acid, or with pyrophosphoric acid alone, and then with alcohol, violet-red needles of **cobaltic chloropentamminohydropyrophosphate**, $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{H}_2\text{P}_2\text{O}_7$, are formed. The salt is sparingly soluble in cold water, easily soluble in hot water; and with dil. hydrochloric acid, it forms the chloro-chloride, and with hydrofluosilicic acid, the chloro-fluosilicate.

C. and M. Duval prepared **sodium cobaltic pyrophosphatopentamminocobaltate**, $\text{Na}[\text{Co}(\text{P}_2\text{O}_7)(\text{NH}_3)_5]$.

C. D. Braun⁵ obtained a **cobaltic hexamminochlorometaphosphate**, which F. M. Jäger represented by the assumed formula: $[\text{Co}(\text{NH}_3)_6]\text{Cl}(\text{PO}_3)_2 \cdot n\text{H}_2\text{O}$. It was obtained by evaporating the mother-liquid obtained in the preparation of the hydrophosphate. The reddish-yellow scales were found by F. M. Jäger to be rhombic bipyramids with the axial ratios $a : b : c = 0.9866 : 1 : 1.044$.

 ——— -sexiesethylenediamines, 710
 ——— salts, 710
 Tetramethylammonium ferric fluoride, 7
 ——— fluoerrate, 8
 ——— tetrachloroferrate, 101
 Tetrasodium cobaltous trimetaphosphate,
 854
 ——— ——— octohydrate, 855
 Thallie cobaltous octochloride, 646
 Thallous cobaltous disulphate, 782
 ——— enneaffuoferrate, 8
 ——— ferric alum, 349
 ——— ——— disulphate, 349
 ——— ——— pentachloride, 105
 ——— ferrous sulphate, 300
 ——— pentachloroferrate, 105
 Thallium cadmium voltaite, 353
 ——— cobalt alloys, 536
 ——— cobaltic hexamminosulphate, 791
 ——— ferrous voltaite, 353
 ——— magnesium voltaite, 353
 Thénard's blue, 519
 Thomaite, 355
 Thoran, 542
 Thorium cobaltous nitrate, 828
 Tilkerodite, 424
 Tin-cobalt alloy, 536
 Titanium-cobalt alloys, 536
 ——— cobaltic hexamminofluoride, 610
 Towanite, 184
 Transvaalite, 424, 586
 Trichlorophosphatoferric acid, 409
 Tricobaltic diaquo-pentol-hexammines, 710
 ——— ——— tetrol-quaterethylenediamines,
 710
 ——— ——— diphosphatobisethylenediamines, 710
 ——— ——— diphosphatobispropylenediamines, 710
 ——— ——— hexol-hexammines, 710
 ——— ——— salts, 710
 Tricobaltous disodium trimetaphosphate,
 854

Tricobaltous disodium trimetaphosphate,
 henicosihydrate, 854
 ——— sodium trimetaphosphate, 854
 Triethylammonium ferric chlorotribromide,
 125
 ——— ——— trichlorobromide, 125
 ——— ——— fluoride, 7
 ——— fluoerrate, 8
 ——— pentachloroferrate, 101
 ——— tetrachloroferrate, 101
 Triphylite, 396
 Triplite, 396
 Triploidite, 396
 Tripotassium sodium ferrous hexachloride,
 32
 Troilite, 136
 Tungsten-aluminium-cobalt alloys, 542
 ——— -chromium-cobalt alloys, 542
 ——— -cobalt alloys, 541
 ——— ——— -iron alloys, 554
 ——— ——— ——— -chromium alloys, 554
 ——— ——— ——— tritacarbide, 541
 ——— ——— ——— molybdenum-chromium-cobalt alloys,
 543
 Tungstyl cobaltic hexamminofluoride, 610
 Turquoise green, 519
 Tully, 419

U

Uranium-cobalt alloys, 543
 Uranyl cobaltic hexamminofluoride, 610
 ——— cobaltous phosphate, 853
 Urusite, 346
 Utahite, 328, 334

V

Valleriite, 136
 Vallerite, 167, 192
 Vanadyl cobaltic hexamminofluoride, 610
 Vauxite, 395
 Vegasite, 328, 349
 Vilateite, 401
 Villamaninite, 424
 Violarite, 424
 Violobromide, 729
 Vitriol, 242
 ——— green, 245, 248
 ——— ochre, 335
 ——— of Mars, 243
 ——— red, 761
 Vitriolgelb, 343
 Vitrolum viride, 245
 Vitriolocker, 335
 Vitriolum ferri, 245
 ——— martis, 244, 245, 248
 Vivianite, 396
 Volomite, 542
 Voltaite, 328, 352
 Vortmann's fuscousulphate, 674
 ——— salt, 803

W

Wad, 424
 Walleriite, 136

Wasserkies, 200
 Weisskupfererz, 200
 Wenzelite, 396
 Whatonite, 200
 White pyrites, 199
 Widia, 542
 Willyamite, 424
 Winklerite, 424
 Wodanium, 421
 Wodankies, 421

X

Xanthosiderite, 329
 Xanthoxenite, 409

Y

Yellow atrament, 329

Z

Zaffera, 420
 Zaffler, 519
 Zaffre, 420, 519
 Zaphara, 420
 Zapher, 420
 Zaphera, 420
 Zarn med kalkjord förenadt, 355
 Zellpyrites, 218
 Zinc ammonium cobaltous sulphate, 782
 ——— ferrous sulphate, 298
 ——— -cobalt alloy, 532
 ——— -copper alloys, 533

Zinc cobalt hexachloride, 643
 ——— -mercury alloy, 534
 ——— cobaltic aquopentamminobromide, 723
 ——— aquopentamminopentachloride, 661
 ——— aquopentamminoiodide, 745
 ——— chloropyridinebisethylenedia-
 minechloride, 666
 ——— hexamminoiodide, 743
 ——— hexamminopentachloride, 656
 ——— cobaltite, 594
 ——— cobaltous carbonate, 813
 ——— orthophosphate, 852
 ——— sulphate, 782
 ——— tetrachloride, 644
 ——— ferric alum, 348
 ——— chloride, 104
 ——— tetrasulphate, 348
 ——— tetracosihydrate, 348
 ——— tetradecahydrate, 348
 ——— ferrous chlorides, 34
 ——— hydrosulphate, 298
 ——— sulphate, 297
 ——— sulphide, 167
 ——— trisulphate, 298
 ——— dihydrate, 298
 ——— octodecahydrate, 298
 ——— green, 519, 602
 ——— iron spar, 359
 ——— pentafluoferrate, 8
 ——— percobaltite, 602
 ——— potassium cobaltous sulphate, 782
 ——— ferrous sulphate, 298
 ——— römerite, 348
 Zirklerite, 35
 Zwieselite, 396, 397
 Zwiselite, 396

END OF VOL. XIV
